ABSTRACT

Background: *To measure neck circumference and waist circumference, to compare it between normal and overweight/obese adolescents and to validate these with body mass index.*

Methods: *A cross-sectional study was conducted in 500 school going children/adolescents. Body mass index, waist circumference and neck circumference were measured. Independent samples t-test and Pearson's correlation were used as tests of significance to analyse quantitative data.*

Results: *A positive correlation of neck circumference and waist circumference with body mass index was observed. The neck circumference and waist circumference in overweight/obese adolescents were significantly higher than adolescents with normal body mass index (P<0.001). Area under curve of waist circumference was more than area under curve of neck circumference. Cut off value of neck circumference for screening adolescent obesity in boys and girls were 30.73 cm, and 29.73 cm, respectively, and waist circumference cut off value were 70.73 cm for boys and 69.23 cm for girls at fairly good levels of sensitivity and specificity.*

Conclusion: *Neck circumference and waist circumference may be used in clinical practice and epidemiological studies as an index of overweight/obesity among school-going adolescents.*

Key words: *Anthropometry, Body mass index, Neck circumference (NC), Waist circumference (WC), Area under curve (AUC).*

INTRODUCTION

Overweight and obesity used to be the problems of developing countries, but recently it is on increasing trends in developing countries too, due to cross cultural interactions, aggressive marketing by food industries and increasing sedentary life style.[1] Central obesity being main predicter of obesity related disorders, body mass index (BMI) may not be the best indicator of functional consequences of obesity.[2] Calculation and interpretation of BMI is difficult & time consuming by field worker sometimes and varying with age. Neck circumference (NC) on contrary may be a good marker to judge subcutaneous fat& obesity, a new concept in the anthropometry. Measuring NC and Waist circumference(WC) by tape is easy and can be taken by health staff and social worker, has not been much explored. Thus present study was conducted to evaluate NC & WC as anthropometric measurement for judging overweight/obesity among adolescent and correlate them with BMI.

METHODS

This school and Hospital based study was conducted in Rajsamand district of Rajasthan. For selection of cases, one school was chosen from low (Government school) and high (Public school) socioeconomic status each and cases

attending hospital OPDs. Total 500 students were selected by random sampling following student list in attendance register. Ethical clearance was obtained from institution's ethical committee with permission from Principal/ Headmaster of the school prior to study.

Healthy children were included in the study. Children with any condition affecting the measurement of NC such as Goitre, swelling/cyst neck, cranio-vertebral diseases/ anomalies were excluded. The cases with Cushing Syndrome/steroid ingestion (Nephrotic syndrome, Bronchial asthma, Collagen vascular disease), Malnutrition, HIV, Malignancies and chronic illnesses were also excluded.

Weight was taken in light clothes without shoes from digital weighing machine. Height was measured by vertical scale, without shoes. Children were categorised according to their BMI, using BMI percentile of Indian Children from 5-17 years with 3rd, 10th, 25th, 50th, 75th and 95th percentile and at 18 years two more percentiles (23 & 28 kg/m^2) were also added.[3] WC was measured by non-stretchable tape at midpoint between costal margin and iliac crest in midaxillary line in standard position at the end of gentle expiration.[4] NC was measured by same tape in standing position with head erect at the level of thyroid cartilage.[5] Anthropometry was performed by trained Paediatric nurse/resident. Data were analysed by using independent t test and Pearson's correlation. Receiver operating characteristics (ROC) analysis was done to find optimal and maximal sensitivity & specificity for NC/WC against BMI. The cut off value of these were determined by Yonden Index (Sensitivity + Specificity – 1). A p-value of <0.05 was considered to be statistically significant.

RESULTS

The age of adolescents recruited in the study (n=500; 55% boys) varied from 10-16 years with a mean SD age 13 (1.4) years. The study sample consisted of 390(78%) with normal BMI, 60(8%) with overweight/ obesity and 50(6.66%) with underweight children. The mean (SD) BMI of boys and girls were 18.4(4.5) and18.6(4.3) kg/m^2 respectively. The mean (SD) waist circumference (WC) for boys and girls were 68.6(12.4) and 66.3 (9.4) cm respectively. There was significant difference (P<0.001) in WC & NC between adolescents with normal and high BMI for both sexes (Table 1).

Table 1: Anthropometric Measurements in Adolescents in the study

BOYS	With (N) BMI	Overweight/ Obese	P Value
Height (cm)	151.6 (13.09)	155.2 (13.05)	<0.001
Weight (Kg)	38.5 (9.87)	59.78 (14.19)	-
WC	64.5 (8.58)	80.48 (12.57)	-
NC	28.9 (2.56)	32.65 (2.68)	-
GIRLS			
Height	147.6(8.3)	148.9(9.3)	<0.05
Weight	36.89(7.0)	54.29(10.1)	<0.001
WC	63.00(7.48)	74.5(8.5)	<0.001
NC	28.18(2.2)	31.06(2.4)	<0.001

All values in Mean (SD)

All values in Mean (SD); for (N) BMI, n =215 for boys and n=175 for girls; and for overweight/obese n=33 for boys and n= 27 for girls.

BMI was positively correlated with NC (r=0.644 for boys, 0.613 for girls) and WC(r=0.691 for boys, 0.681 for girls) at significant level (p=<0.001). For boys 3rdpercentile of NC was 24.9 cm & 97th percentile was 35.95 cm and for girls, 3rd percentile was 24.1 cm and 97th percentile was 34.9 cm.

Table 2 shows values of area under the curve (AUC) and cut off values for WC and NC with their respective sensitivity & specificity levels in identifying children with overweight/ obesity.

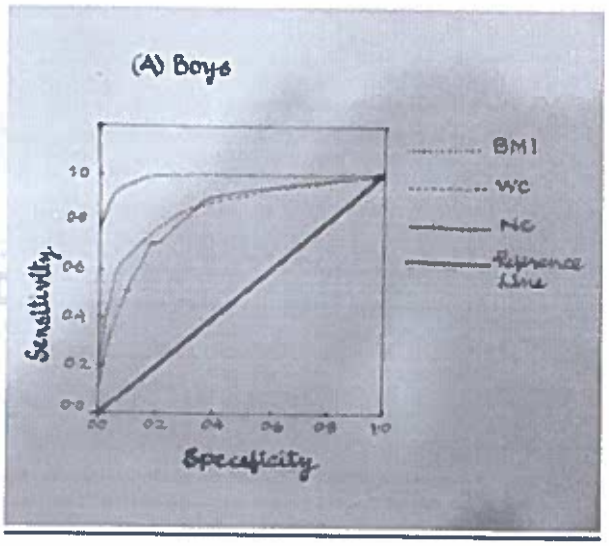
Table 2 also shows the comparison of NC as a tool for detection of overweight/obesity as compared to WC.

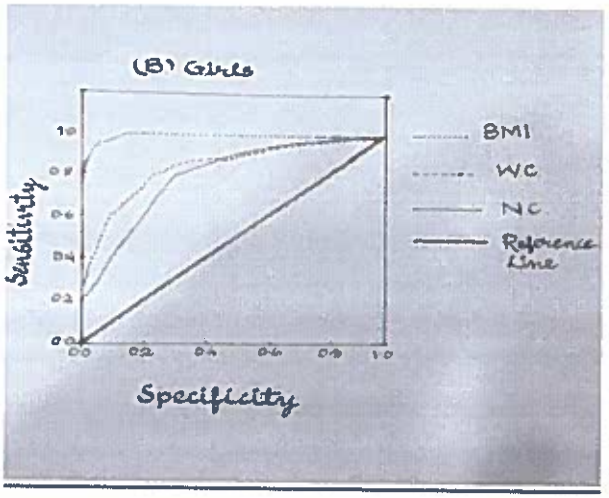
Table 2: Performance of NC in detecting overweight/ obesity

	AUC	95% CI	Cut off	Sensationally	Specificity
WC	Boys 0.885	0.837, 0.894	70.73	82.7	77.2
	Girls 0.849	0.821, 0.879	69.23	74.4	81.0
NC	Boys 0.821	0.793, 0.852	30.73	78.9	68.6
	Girls 0.815	0.784, 0.844	29.73	71.9	77.0

Fig. 1 ROC curve comparing neck circumference and waist circumference with body mass index (BMI) in boys (A), and girls (B).

WC-waist circumference and NC- neck circumference.





DISCUSSION

In this study, it is found that a significant difference in WC & NC among normal and overweight/obese children detected by BMI(p=<0.001) in both boys and girls. Also there was a strong positive correlation of NC as well as WC with BMI.

Limitations of the present study includes enrolments of adolescents from small geographic area, sample size and lack of validations of these measurements with functional consequences of obesity.

It was found that cut off values of NC for screening adolescent obesity in boys and girls was 30.73 cm & 29.73 cm. respectively while for WC 70.73 cm. and 69.23 cm. for boys and girls respectively. These results are close to estimates from previous studies.[1,2] Small differences between cut off could be explained by ethnic variations.[5,7] Correlation of NC & WC with BMI has also been reported in studies.[5,7,8] It was observed that AUC of >80% for both NC & WC in boys and girls including its accuracy to detect adolescents with increased BMI. Further AUC for WC was found to be more as compared to NC in girls (0.849 vs 0.815) and boys (0.885 vs 0.821) indicating WC may be better measure for obesity in adolescents, however several limitations have been documented in the literature either related to its measurements,[7] specially among the adolescents owing to body changes they experience during puberty or due to its variations throughout the day according to bowel function or menstrual period.[9] Measurement of NC may be relatively simple, convenient and nonintimidating specially for adolescents. As compared to BMI, Waist to hip ratio, Neck &Waist circumference have been shown to have high accuracy in predicting the risks of atherosclerosis in middle aged adults.[10]

CONCLUSION

Thus, we conclude that both NC & WC are useful screening tools for adolescents with overweight/obesity and have a potential to be used as screening tool for adolescent overweight/obesity.

Bacteriological Profile and Antibiotic Sensitivity Pattern in Community Acquired Neonatal Sepsis in Rajsamand – A Hospital Based Prospective Study

SK Tak[1], Anup Paliwal[2*], Sameer Jagrwal[3]

[1]Associate Professor, [2]Assistant Professor, [3]Senior Resident, Department of Paediatrics, Ananta Institute of Medical Sciences and Research Centre, Rajsamand, Rajasthan, India.

ABSTRACT

Background: *To isolate the pathogenic bacteria and to know the antibiotic sensitivity in the community acquired neonatal sepsis.*
Materials & Methods: *It was a prospective study undertaken on 120 neonates suspected of community acquired neonatal sepsis admitted in Pediatrics Department of AIMSRC over a period of two year. All these cases fulfilled the inclusion criteria required for the study. Blood culture of these cases was performed by Mackie and McCartney method and antibiotic sensitivity by Kirley-Baner's disc diffusion method.*
Results: *Out of 120 cases, 88 cases showed positive blood culture. Gram negative isolates (N=55) were more frequent than gram positive isolates (N=33). Most common isolate was Klebseilla, Pneumoniae followed by Staphylococcus Aureus, E. Coli, Pseudomonas Aeroginosa, Acinetobacter. Both gram negative as well as gram positive isolates showed high resistance to ampicillin and gentamycin. Gram negative isolates were highly sensitive to Colistin Sulphate and Meropenem whereas gram positive isolates were highly sensitive to Linezolid and Vancomycin.* ***Conclusion:*** *Gram negative bacteria were more frequent causes of community acquired neonatal septicemia than gram positive isolates. Both gram positive and negative isolates showed poor sensitivity towards conventional first line antibiotics, rather were mainly susceptible to higher antibiotics. So, the knowledge of the pattern of bacteriological isolates and their antimicrobial susceptibility pattern can be very helpful for prompt treatment of such patients, to decrease neonatal morbidity and mortality as well as reducing the emergence of multi-drug resistant organisms.*

INTRODUCTION

Neonatal Sepsis refers to the invasive bacterial infection occurring in the first 4 weeks of life. It encompasses various infections of the new born like septicemia, meningitis, arthritis, osteomyelitis and urinary tract infection but excludes superficial infections like conjunctivitis and oral thrush.[1] It can be early onset sepsis(EOS) presenting within 72 hours of life with maternal genital tract being the main source of infection or it can be late onset sepsis (LOS) which usually presents after 72 hours of life and the main source of infection is nosocomial (hospital acquired)or community acquired infection.[2,3] Neonatal sepsis, the commonest cause of neonatal morbidity and mortality is responsible for 30-50% of total neonatal deaths each year in the developing countries.[4-6] According to the World Health Organization (WHO) estimate, there are about 5 million neonatal deaths per year in the world, 98% of these occurring in the developing world. Neonatal mortality rate in developing countries from various causes is about 34 per 1000 live births, most of the deaths occurring in the first week of life. Globally, major causes of the neonatal deaths are due the prematurity (28%), sepsis (26%), and birth asphyxia (23%).[7] The incidence of the neonatal sepsis according to the Neonatal and Perinatal Database (NNPD) is 30 per 1000 live births. The NNPD network comprising of the 18 tertiary care neonatal units across India found sepsis to be the commonest cause of neonatal mortality contributing to 19%

Source of Support: Nil, **Conflict of Interest:** None

of all neonatal deaths.[8] In India, sepsis has been reported as a cause of neonatal deaths in 20-50% of cases in the community based studies.[9,10] The gold standard for the diagnosis of neonatal sepsis is isolation of bacterial agents from the blood culture.[11] Both gram negative and gram positive bacteria have been isolated from the blood and predominance of one type over the other varies from place to place and even in the same place over the time to time.[12] In most of the developing countries, gram negative sepsis remains the major cause of the neonatal septicemia. Commonly isolated organisms include Klebseilla Pneumonia, Escherichia Coli, Enterobacilli, Pseudomonas Aeruginosa, Staphylococcus Aureus, Streptococcal Species, Citrobacter Species and Coagulase Negative Staphylococcus (CoNS).[13,14] So, this study was undertaken with the aim to determine the bacteriological profile and its antibiotic susceptibility pattern in the community acquired neonatal sepsis. Following a rational antibiotic therapy, we can minimize the risk of severe neonatal morbidity and mortality as well as decrease the development of multidrug resistant bacteria.

METHODS

It was a hospital based prospective study conducted in the department of Pediatrics, AIMSRC, Rajsamand. It included 120 neonates admitted with clinically suspected community acquired sepsis during the period of two year. Only those neonates were included who were less than 28 days of life, had clinically suspected septicemia and presented after 72 hours of birth. Neonates of more than 28 days of life or presenting before 72 hours of life or already on antibiotics were excluded from the study. Sepsis was suspected from the clinical history of one or more of the symptoms like refusal to feed, lethargy, fever, abdominal distension, loose stools, vomiting, features of hypoglycemia, hypothermia, tachypnea, tachycardia, grunting, chest retractions, cyanosis, apnea, pallor, shock, excessive crying, body mottling, poor cry, prolonged capillary time, bleeding from any site, neck retractions and vacant stare. With all the recommended aseptic precautions, 1ml of blood was drawn from each neonate and collected in a sterile bottle containing 1%glucose broth and inoculated at 37^{0}C. Subcultures were made on blood agar and Mac-Conkey agar after 24 hours, 48 hours, 72 hours and 7 days which were further inoculated at 370C for 18-24 hours. The plates were observed the next day. If no growth was observed even after 7th day, sample was reported negative for bacterial isolate. The growth of isolates were identified by colony morphology, gram staining and standard biochemical tests described in Mackie and McCartney Practical Medical Microbiology.[16] For identification of gram positive isolates catalase and coagulase tests were done; for gram negative organisms, Simons's citrate test, motility indole test, urea (MIU) test and triple sugar test (TST) were done. Antibiotic susceptibility test was performed on the and identified isolates using commercially prepared antibiotics disks (High media Co. Mumbai, India) on Muller Hinton agar by Kirby-Baur Disk Diffusion method as recommended in the Clinical Laboratory Standard Institute (CLSI) guidelines.[15]

RESULTS

Out of 120 study cases, 73 (61.24%) were males and 47 (38.76 %) were females. Three most frequent features suggestive of septicemia were refusal to feed (n= 92; 77%), lethargy (n= 80; 66.66%) and fever (n= 59; 49 %) followed by other clinical features. 88 (73.33%) showed positive blood culture and 32 (26.66 %) showed no bacterial growth. Gram negative isolates (n =55; 62.5 %) were more frequent than gram positive growths (n=33; 37.5 %). The most common pathogen isolated was Klebseilla pneumoniae (n= 28) followed by other organisms and CONS was the least common bacterial isolate [Table 1]. The gram-negative isolates showed high resistance to Ampicillin and Gentamycin but were highly sensitive to Colistin Sulphate and Meropenem [Table 2]. Gram positive isolates were also quite resistance to Ampicillin and Ceftazidime but were highly sensitive to Linezolid and Vancomycin [Table 3].

Table 1: Organisms Isolated.

Organisms Isolated	Number(N=88)	Percentage
Gram Negative (55)		
Klebseilla Pneumonia	28	31.81
Escherichia Coli	14	18.33
Pseudomonas	12	16.12
Acinetobacter	3	3.62
Gram Positive (33)		
Staphylococcus Aureus	22	28.85
Enterococcus	1	1.28
Coagulase Negative Staphylococci (CoNS)	7	

Table 2: Antibiotic Susceptibility Pattern of Gram Negative Isolates. (n=55)

Antibiotic	Gram Negative	Percentage
Amikacin	34	61.8
Gentamicin	21	38.1
Ceftriaxone	24	43.6
Piperacillin-Tazobactam	23	41.8
Imipenem	53	96.36
Colistin Sulphate	54	98.18
Ceftazidime	25	46.28
Ciprofloxacin	36	65.4
Ampicillin	2	3.63
Cefotaxime	25	46.28
Cefoperazone	26	46.78

Table 3: Antibiotic Susceptibility Pattern of Gram Positive Isolates. (n=33)

Antibiotic	Gram Positive	Percentage
Amikacin	30	90.9
Gentamicin	14	42.4
Ceftriaxone	16	48.4
Linezolid	32	96.9
Amoxycillin- Clavulanate	15	45.4
Ceftazidime	4	12.1
Vancomycin	31	93.9
Ciprofloxacin	18	54.5
Ampicillin	2	6
Cefotaxim	17	51.5
Methicillin	29	87.8
Cefoperazone	18	54.5

DISCUSSION

Neonatal Sepsis is a life-threatening emergency and any delay in its treatment may lead to mortality.[4,7] Bacteriological profile of community acquired neonatal sepsis changes from region to region and time to time. In addition, there is increasing multidrug resistance over the last few years.

Therefore, knowledge of pattern of the bacteriological profile and its antimicrobial susceptibility pattern can be very helpful for prompt empirical treatment of neonatal sepsis. This study was undertaken keeping these objectives in mind.

Out of 120 study cases; male to female ratio 1.5:1 which is comparable to other studies like by Begums et al.[16] Reason for male preponderance may be Social and Sex dependent factors as X-linked immunoregulatory genes may play some protective roles in females.[17] Positive blood culture was observed in 73% cases in the present study which is comparable to study by Premlata et al.[18] showing blood culture positivity in 82% cases although the results are higher as compared to Karthikeyan et al.[19] showing blood culture positivity in 51% cases. The difference may be due to variable incidence of neonatal sepsis from place to place and due to many other factors like perinatal care, birth weight etc. Gram negative isolates (62.50%) were more frequent than gram positive (37.50%). These results were consistent with the NNPD data. Out of all culture positive cases, Klebseilla pneumonia was most frequent (31.81%) gram negative isolate and Staphylococcus Aureus was the most common (28.85%) gram positive isolate. These results are similar to many other Indian studies. Most of the gram-negative isolates in the present study were resistant to the routinely used first line empirical antibiotics with 96.15% resistant to Ampicillin and 58.34% to Gentamicin. But all the negative organisms showed 100% sensitivity to Colistin Sulphate to Imipenem. Our findings correlate well to those of Mustafa et al and many other studies.[20] Out of gram positive isolates, again 93.82% were resistant to routinely used first line antimicrobial Ampicillin and 42.40% were resistant to Gentamicin whereas 96.90% gram positive isolates were sensitive to Linezolid, 90.90% were sensitive to Amikacin and 93.90% to Vancomycin. Our findings again correlate well with those reported by Mustafa et al and Kaistha et al.[20,21] Increasing resistance by both gram positive and gram negative isolates to routinely used antimicrobials may be due to inappropriate use of antibiotics.

CONCLUSION

Gram negative organisms were more frequent causes of community acquired (CA) neonatal septicemia than gram positive isolates. Klebseilla Pneumoniae was the most common, Staphylococcus Aureus was the second most common and CoNS was the least common organisms isolated. Both gram negative and gram positive showed poor sensitivity towards routinely used first line antimicrobials like Ampicillin and Gentamicin. Gram-negative organisms were highly sensitive to Colistin Sulphate, Imipenem, Ciprofloxacin, Amikacin and third generation Cephalosporins in the descending order. Gram-positive isolates were mainly sensitive to Linezolid, Amikacin, Vancomycin, Methicillin, Ciprofloxacin and third generation Cephalosporins in descending order. Therefore, the bacteriological profile and the sensitivity pattern of Community acquired neonatal septicemia in a particular geographical area must be considered before deciding the empirical antibiotic treatment of community acquired neonatal septicemia.

Knowledge, Attitude and Practice Study About Use of ORS in Diarrhea in Mothers with Children 02-05 Year Age Group Residing in Various Urban Slums of Bhopal City

Deepti Singh[1], Sunita Lakhwani[2], D.P.S. Gaharwar[3]

[1,2]Associate Professor, Department of Paediatrics, R.K.D.F. Medical College Hospital & Research Centre, Bhopal, [3]Assistant Professor, Department of Paediatrics, R.K.D.F. Medical College Hospital & Research Centre, Bhopal.

Abstract

Background: KAP study for use of ORS in Diarrhea in mothers with children 02-05 year age group. The objective of the study was to assess the Knowledge, Attitude and Practice use of ORS in Diarrhea among mothers at various Urban Slums of Bhopal City. **Subjects and Methods:** A cross sectional descriptive study was conducted among mothers having children 02-05 year age group. All mothers were interviewed through a self designed pretested structured questionnaire regarding use of ORS in Diarrhea of their infants and socio demographic profile. **Results:** Majority of the mothers were illiterate, and not aware about benefits of use of ORS. Although mother's knowledge was lacking but most of mother use of ORS in Diarrhea in their children. **Conclusion:** Most of mothers do not follow practice of use of ORS in Diarrhea and had lack of knowledge. The knowledge regarding method of use of ORS for management of diarrhoea was found to be inadequate in this study. Though many mothers are aware that it is useful most are not aware of its method of use. More measures need to be adopted to improve this knowledge and make mothers aware about the method of use and availability of ORS.

Introduction

Diarrhoea is defined as the passage of three or more loose or liquid stools per day (or more frequent passage than is normal for the individual). Frequent passing of formed stools is not diarrhoea, nor is the passing of loose, "pasty" stools by breastfed babies. Diarrhoeal disorders in childhood reported in large proportion (18%) of childhood deaths, with an estimated 1.8 million deaths per year globally. The World Health Organization (WHO) suspects that there are >700 million episodes of diarrhea annually in children < 5 years of age in developing countries.[1]

The objective of this study was to see the change in knowledge and behavior of the mother acute diarrhea in children 02-05 years of age group. Because almost three decades have passed since commercially available ORS was launched and continued feeding during diarrhea is being stressed.[2,3]

Diarrhoeal disease is the 2nd principal cause of death in children under 05 years old, & is responsible for killing around 760 000 children every year. Diarrhoea can last several days, & can leave the body without the water & salts that are necessary for survival.[4] Most people who die from diarrhoea die from severe dehydration & fluid loss. Children who are malnourished or have impaired immunity as well as people living with HIV are most at risk of life-threatening diarrhoea. It is usually a symptom of an infection in the intestinal tract, which can be caused by a variety of bacterial, viral and parasitic organisms. Infection is spread through contaminated food or drinking-water, or from person-to-person as a result of poor hygiene.[5]

Subjects and Methods

This study was conducted at various Urban Slums of Bhopal City. This cross sectional study was carried out from September 2018 to August 2019. All mothers who have 02-05 years of age group child with diarrhea were enrolled. Total 300 consecutive mothers with written informed consent were taken.

A predesigned & pretested questionnaire was prepared comprising of nearly 20 questions, most of the questions were close ended. Besides literacy, socioeconomic status was also noted. Questions pertained to practices towards diarrhea, nutrition during diarrhea and awareness of ORS. A single interviewer interviewed all 300 mothers who have 02-05 years of age group child for diarrhea and related diseases.

It took nearly 15-20 minutes to finish one interview & on a single day, not more than 5 interviews were carried out. At the end of each interview, the mothers were provided with health education to improve their knowledge of diarrhea, nutrition during diarrhea and oral rehydration therapy, with practical demonstration of correct ORS preparation. Also, the mothers were handed over a health education pamphlet in Hindi pertaining to diarrhea and ORS at various Urban Slums of Bhopal City, to improve their knowledge and management skills in the future. The data was calculated in Microsoft Excel and interpreted as mean and percentages.

Inclusion Criteria:

Mothers with children of 02 to 05 yrs age group, who are permanent residents of urban slums.

Exclusion Criteria:

1. Mothers with either less than 02 years or more than 05 yrs age group children.
2. Mothers with children who are critically ill, hospitalized or on medication.
3. Mothers who are guests or temporary residents of urban slums.

Results

Table 1: Age of Mothers

Age of mother	No. of mother (n = 300)	Percentage of mother
Below 25 years	53	17.66
25-35 years	179	59.66
35 years and above	68	22.68

In our study, 59.66% were in age group of 25-35 years, followed by 22.68 were 35 years & above & 17.66% were below 25 years.

Table 2: Education of Mothers

Education of mothers	Number of mothers (n = 300)	Percentage of mother
Intermediate	21	7.00
Primary	97	32.34
Illiterate	182	60.66

In our study, 60% were Illiterate mothers, followed by 32.34 Primary & 7% were Intermediate.

Table 3: Knowledge, Attitude and Practice study about use of ORS in Diarrhea in mothers

S. No.	Parameter	Number of mothers (n = 300)	Percentage of mothers
1	Did not know the exact definition of diarrhoea	267	91%
2	Aware that diarrhoea leads to dehydration	79	26.33%
3	Food contamination causes diarrhea	98	32.66%
4	Rice based feeds are best in diarrhea	112	37.34%
5	Oral fluids should be increased in diarrhea	96	31.88%
6	Aware of ORS but not practising it	217	72.53%
7	Unaware of ORS	179	59.66%
8	Wrongly preparing ORS	193	64.29%

193 mothers said that they one or the other time used wrong commercial preparation like Sporolac/Lactrol as ORS. Nearly 91% of the mothers did not know exactly how much ORS is to be given with each loose stool.

Discussion

Diarrhoea stays one of the main worldwide reasons for death among youngsters younger than two years. ORS is straightforward, exceedingly compelling, economical and suitable treatment for diarrheal drying out and since the presentation of ORS in 1979, there has been an unfaltering decrease in passing because of diarrheal ailments6. Diarrhoea is the frequent (typically characterized as at least three times in multi day) passage of liquid or soft stool7,8. It is the most widely recognized clinical indication of gastrointestinal infection and the second driving reason for death on the planet among kids under two years old. Unfortunately, particularly in creating nations, because of absence of legitimate information in mother, with respect to accessibility, planning and utilization of ORS, this objective is a long way from accomplished.

Although use and availability of ORS can reduce the morbidity and mortality associated with diarrhoeal diseases it is far from being highly effective especially in developing countries due to lack of awareness about availability and use of oral rehydrating solution for management of diarrhoeas.9 Also complicating the issue is lack of understanding regarding the role of sanitation and hygiene in reducing the incidence of diarrhoea.[10] In present study, although 75% of the mothers were educated, only 156 knew the correct method of ORS preparation and its use whereas out of the remaining mothers who knew about ORS did not know the correct method of using ORS.[11] In fact, people adopt a wait and watch approach as it is believed the consumption of food and water increases the bulk of stools and does not provide rest to the intestine which is necessary for recovery from diarrhoea. Even some of the educated people do the same thing.[12]

Conclusion

Most of mothers do not follow use of ORS in Diarrhea practices and had lack of knowledge was found. The

knowledge regarding method of use of ORS for management of diarrhoea was found to be inadequate in this study. Though many mothers are aware that it is useful most are not aware of its method of use. More measures need to be adopted to improve this knowledge and make mothers aware about the method of use and availability of ORS.

Knowledge, Attitude and Practice Study about Complementary Feeding in Mothers with Children Upto 02 Years Age Group in Urban Slums across Bhopal City

Deepti Singh[1], Sunita Lakhwani[2], D.P.S. Gaharwar[3]

[1,2]Associate Professor, Department of Paediatrics, R.K.D.F. Medical College Hospital & Research Centre, Bhopal, [3]Assistant Professor, Department of Paediatrics, R.K.D.F. Medical College Hospital & Research Centre, Bhopal.

Abstract

Background: Objective of our study was to assess the knowledge, attitude and practice of complementary feeding among mothers in various Urban Slums across Bhopal City. **Subjects and Methods:** A cross sectional study was done about knowledge of mothers with children below 2 years of age with help of pretested self designed questionnaire based interview who are attending Anganwadi Centre & Slum Areas. **Results:** In our study most of mothers did not know correct time of starting complementary feeding, they also did not know what food can be given, frequency and amount of complementary feed. **Conclusion:** Knowledge of Mother's concerning timing of complementary feeding is inadequate and practice and attitude are inappropriate. Majority of them are not aware of the current recommendations. Health education about correct feeding should be given to mothers and family members including appropriate time for complementary feeding initiation, complementary foods, it's preparation and practices to give on proper time and amount and hygiene. It will help to prevent malnutrition, infant and under 5 mortality and morbidity and improve the health status of children. Correct information and guidelines about complementary feeding is not reaching the target population. False beliefs, customs and attitude of the mother tend to wean the child late. Poor breastfeeding and inappropriate complementary feeding practices are the principal proximate causes of malnutrition during the first two years of life. Study Design: Cross Sectional Study

Introduction

World Health Organization (W.H.O), Complementary feeding is the process starting when breast milk alone is no longer adequate to meet the nutritional requirements of infants, & consequently other foods and liquids are needed, along with breast milk. The change from exclusive breast feeding to family food referred to as complementary.[1]

Breast feeding is well renowned while early age to be the best feeding for a neonate. Early breastfeeding within 01 hour and for first 06 months related to child malnutrition & mortality respectively.[2] In India effective implementation of these interventions is yet to be achieved. Proper initiation & continuation of breast feeding in children under 06 months is only 46.4%.[3] To formulate any effective strategy to improve infant nutrition it is imperative to have an insight into existing knowledge, attitude and practices about infant feeding practices existing in the community.[4]

Subjects and Methods

A cross sectional study was conducted at Anganwadi Centre & Slum Areas of Bhopal between August 2018 to July 2019. Mothers of children age below 2 year of various Urban Slums across Bhopal City were included in the study. Well informed written consent was taken by all mothers, Mothers with older children and non willing to participate were excluded. During study 300 mothers were interviewed through a self designed pre tested structured questionnaire based on extensive literature search and WHO and national guidelines. The questionnaire included socio-demographic variables, starting time for complementary feeding, complementary food, frequency and amount of feed, liquid, semisolid and solid food, homemade or readymade food, their knowledge about hygiene in food preparation and feeding, finger foods. Total thirty two questions were asked in interview. The questions had single as well as multiple correct options, some were open ended and others were with

options all questions asked by doctors after explaining mother about study.

Inclusion Criteria-

All mothers living in urban slums, with up to 2 yrs age group child.

Exclusion Criteria-

1. Visitors to the slums.
2. Mothers with child who is more than 2 yrs of age
3. Sick children, children with serious illnesses or children on medication.

Statistical analysis

Statistical analysis was done by using descriptive and inferential statistics using chi square test. Software used in analysis was SPSS 20.0 version. P Value < 0.05 is considered as level of significance.

Results

Table 1: Comparison of demographic profile to Knowledge of Mothers about Complementary feeding

Table 1A: Education of mothers

Education of mothers	Number of mothers	Knowledge of mothers about complementary feeding			P-Value
		Good	Average	Poor	
Primary	84	29	33	22	0.031 Significant
Illiterate	216	27	109	80	

P Value is less than 0.05, hence it is significantly associated.

Table 1B: Number of children

Number of children	Number of mothers	Knowledge of mothers about complementary feeding			P-Value
		Good	Average	Poor	
One child	104	15	47	42	0.042 Significant
More than one child	196	24	110	62	

P Value is less than 0.05, hence it is significantly associated.

Table 1C: Age of Mother

Age of mother	No. of mother	Knowledge of mothers about complementary feeding			P-Value
		Good	Average	Poor	
Below 30 years	186	16	91	79	0.032 Significant
30 years and above	114	23	58	43	

P Value is less than 0.05, hence it is significantly associated.

Table 1D: Income / Month

Income / Month	Number of mothers	Knowledge of mothers about complementary feeding			P-Value
		Good	Average	Poor	
Above 10,000 Rs	89	09	47	33	0.96 Not Significant
Below 10000 Rs	211	18	112	81	

P Value is greater than 0.05, hence it is not significantly associated.

Table 2: Knowledge of mothers about complementary feeding

S. No.	Complementary feeding Knowledge	Good	Average	Poor
1	Meaning of complementary feeding	64	156	80
2	Time to start	42	184	74
3	Amount of feed	62	174	64
4	Frequency of feed	104	114	82
5	Food can be given	82	152	66
6	Hygine practices	56	116	128
7	Liquid, Semisolid and solid diet	40	196	64

Discussion

Exclusive breastfeeding is recommended worldwide as the ideal feeding for first six months of life. For successful lactation, timely initiation of breastfeeding i.e. within ½ hr of normal delivery and within 4 hrs of caesarean delivery is essential. In fact a recent study from Ghana found that 22% death among newborn can be prevented if they are given breastfeeding within one hr of birth.[5] In present study only half of the total mothers knew about this fact (57% urban and 46.7% rural). Likewise only 63.3% urban and 40% rural mothers knew about correct period of exclusive breastfeeding. As far as maximum period of breastfeeding (i.e. up to 2 years) is concerned, only 40% of urban and 36% of rural mothers were knowledgeable about it.

The women who had history of antenatal care visit during pregnancy period and post natal visit initiate complementary feeding timely. A study in Ghana, Harar, Tigrai found out that timely initiation of complementary feeding is become higher with antenatal and Post natal, maternal education, antenatal care and Post natal care.[6,7] Mothers who have No post natal visit in Health institution were start early complementary feeding as compared to mothers who have follow up. These finding is supported by study conducted by South West Ethiopia.[8] This is explained Mothers who get Health education and advice on complementary feeding during Post natal visit has great effect t on the timely initiation of complementary feeding. In this study more than two third 139 (69.5%) of mothers had history of ante natal care visit during their pregnancy period from which the majority (59.0%) have had more than three times. This is higher than study in Uganda that only 47% of women receive antenatal care coverage.[9] This may be due the low overall antenatal care coverage of in the country.

Conclusion

Knowledge of Mother's concerning timing of complementary feeding is inadequate and practice and attitude are inappropriate. Majority of them are not aware of the current recommendations. Health education about

correct feeding should be given to mothers and family members including appropriate time for complementary feeding initiation, complementary foods, it's preparation and practices to give on proper time and amount and hygiene. It will help to prevent malnutrition, infant and under 5 mortality and morbidity and improve the health status of children. Correct information and guidelines about complementary feeding is not reaching the target population. False beliefs, customs and attitude of the mother tend to wean the child late. Poor breastfeeding and inappropriate complementary feeding practices are the principal proximate causes of malnutrition during the first two years of life.

Abstract

Aim: To study Hypothermia in infants of less than 2 months of age in urban slums of Indore city. **Methods:** Retrospective, cross-sectional observational study of 411 infants of below 2 months of age. **Period of study:** 1 year (August 2015 to August 2016) **Results:** Infants below 2 months of age when studied in home deliveries; conducted by Trained Birth Attendant's- 19% were having 'hypothermia by maternal perception' Immediately after birth only 47% were covered fully, 52% were only partially covered, while 1% were not at all covered. Immediately post delivery only 24% were kept in skin-to-skin contact with mother. First bath immediately post birth was given in 57% infants. **Conclusion:** In urban slums of Indore city, in home deliveries 19% of newborns were suffering from hypothermia even when deliveries were attended by Trained Birth Attendant. This can be attributed to faulty newborn care practices.

Keywords: Hypothermia, Neonatal care, Newborn, Urban slums

Introduction

Many practices in midwifery care are prevalent without ever having been properly assessed. Perinatal routine care in urban slums seems to be in particular need of assessment. Birth asphyxia and hypothermia are common antecedents of excessive morbidity and mortality in the neonatal period. The prevention of neonatal hypothermia in uncompromised newborns is dependent on the degree of adherence to simple routines after birth. These routines are- wiping and wrapping the baby, keeping the delivery room warm and giving opportunities for early breast feeding. The newborn responds differently to hypothermia-by 'non shivering thermogenesis'- a metabolic process whereby oxygen consumption is raised independently of muscle activity; occasionally transient shivering can be observed [1] but mostly newborn responds to cold stress by changing its position in an attempt to decrease its body surface.

Manuscript received: 16th September 2016
Reviewed: 28th September 2016
Author Corrected: 15th October 2016
Accepted for Publication: 27th October 2016

First bath and hypothermia: Bathing the newborn is a common routine mostly to remove the 'dirty skin'- the 'vernix caseosa'. Vernix is actually a product of fetal skin representing physiological and sterile coverage of parts of the fetal body beyond 34 to 36 wks of normal pregnancy. It has no infected material and on the contrary it has got antibacterial properties that may contribute to the protection of the newborn from bacterial infections.

Methods

This study was conducted over a period of 1 year at the Aanganwadi centres of various urban slums of Indore city at M.P. state. For these purpose 411 subjects of age 0-2 months were randomly selected.

Inclusion criteria: All term Neonates and infants up to age 2 months who are permanent residents of urban slums of Indore city

Exclusion criteria: More than 2 months old preterm or sick newborns who needed admission in NICU within 7 days after birth or who were delivered in institutes and children of guests or relatives from other places were excluded from the study. Mothers were explained about the aims, objectives and type of study. They were asked if they understand the term 'hypothermia by maternal perception'. Only those mothers were included who had home delivery conducted by Trained Birth Attendant. Mothers who had recollection of perceiving body temperature of infants less than 2 months old, were included.

Pre-conceived and printed questionnaire was used as proforma and filled by both the investigators themselves; based on mothers interview.

Data was collected, tabulated and analysed statistically. As this is a one-time single observation study, Confidence Interval (CI) was chosen as the best tool to gather reliable data; narrower the range, more the confidence in the data. The calculation of 95% CI was done by method described by J.E.Park [2]

95% Confidence Interval (CI): it is the range of 95% confidence in any data To calculate CI, SEP (Standard Error of Proportion) is calculated as follows: SEP= $\sqrt{(pq/n)}$
Where,

P= proportion of parameter for which 95% CI is to be calculated

Q= proportion of the rest of the parameters

N= sample size

95% CI= SEP×1.96±p

i.e. (SEP ×1.96CI)+p to (SEP×1.96 CI)-p

For every parameter 95% CI is calculated.

Results

In home delivery 19% newborns were hypothermic by maternal perception (95% CI-0.15-0.22). Only 47% newborns were fully covered with cloth (95% CI-0.43-0.51) and only 24% were kept in skin contact with mother (95%CI-0.19-0.28), most of the babies (57%) were given bath immediately (95%CI-0.52-0.61).

Table-1: Distribution according to Hypothermia by maternal perception (Home delivery)

Hypothermia	No.	%	95% CI
Yes	78	19	(CI-0.15-0.22)
No	333	81	(CI-0.77-0.84)
Total	**411**	**100**	

Hypothermia was present in 19% of subjects (95%CI-0.15-0.22)

Table-2: Distribution according to way of covering the baby

Baby covered as	No.	%	95% CI
Head covered	8	2	(CI-0.006-0.03)
Head +body covered	193	47	(CI-0.42-0.51)
Only body covered	206	50	(CI-0.45-0.54)
not covered	4	1	(CI-0.0004-0.02)
Total	**411**	**100**	

Only 47% were covered fully (95%CI-0.43-0.51)

Table-3: Distribution according to status of Baby-Mother skin-to-skin contact

Whether kept in skin-to-skin contact with mother	No	%	95% CI
YES	99	24	(CI-0.91-0.28)
NO	312	76	(CI-0.71-0.80)
TOTAL	411	100	

Only 24% were kept in contact with mother (95% CI-0.19-0.28)

Table-4: Distribution according to time since birth for first bath

First bath after how many hrs since birth	No.	%	95% CI
Immediately	234	57	(CI-0.52-0.61)
B/w 12-24 hrs	116	28	(CI-0.23-0.32)
B/w 24-48 hrs	35	9	(CI-0.06-0.11)
B/w 48-72 hrs	26	6	(CI-0.03-0.08)
Total	**411**	**100**	

Majority of the newborns (57%) were immediately bathed (95% CI-0.51-0.61)

Discussion

In our study overall incidence of Hypothermia was found to be 19% by maternal perception. Hands and body both were covered in only 47% newborns while 50% were kept with only body covered, 2% only head covered and 1% were not covered at all. Only 24% were kept in skin – to-skin contact with mother, 57% were bathed immediately, 28% between 12-24hrs, 9% within 24-48 hrs and 6% were given bath within 48-72hrs.

A similar study in Zambia [3] found that 30.64% neonates were completely wrapped, which is similar to our study, 20.96% were incompletely wrapped; which is less than our study and 8% were not wrapped at all; which is more than our study. A similar study on uncomplicated newborn infants in Nepal [4] found that hypothermia was present in 2.9% of hospital deliveries; which is less than our study.

A similar study in Shimla [5] found that hypothermia was present in 81% of newborns on first day after birth, which is more than our study. In a community based study in Ambala city [6] incidence of hypothermia was 11.1% which is less than our study. A cross-sectional community based study of care of newborns in Nepal [7]; found that in home deliveries only 4% newborns were wrapped, which is less than our study.

In Uganda: A randomized, controlled trial [8] found that 83% neonates were hypothermic after 1 hour, which is more than our study.

A study was conducted by UHRC[9] with 15025 mothers across 45 slums in Meerut city of UP found that the incidence of hypothermia was 12%, which is similar to our study, 26.5% were kept in contact with mother and 18.8% were wrapped completely; these findings are less than our study.71.5% were wrapped partially, which is more than our study. 32% were bathed immediately, which is less than our study.

A similar study conducted in urban slums of Lucknow city, UP [10] found that 79.7% newborns were bathed immediately, which is more than our study. A study among slum dwellers in Rachna Town, Lahore [11] found that 37.2% newborns were bathed immediately, which is less than our study; 18.8% were wrapped completely, which is less than our study and only 26.5% were kept in contact with mother, which is similar to our study.

A systemic review on similar topic [12] found out that in home deliveries; range of prevalence of hypothermia was from 11 to 92.3%. 92.3% in Sarlahi, Nepal, 82% in Kathmandu, 43% in Uttar Pradesh and 25% in Delhi, which are more than our study and 11% in Haryana, 17% in Gadchiroli; which is less than our study.

Conclusion

The incidence of Hypothermia varies in different regions and seasons. The incidence of hypothermia reported in this study should be taken as minimum as lower environmental temperatures in the night might have increased the incidence during night hours.

Since the relation between neonatal temperature and mortality is shown to be linear; appropriate practices

like-warm delivery room, immediate drying and skin to skin contact with mother for first hours after birth and delaying first bath must be followed. While promoting the programme for prevention of neonatal hypothermia, caution should be taken to modify the guidelines according to the specific environmental situation.

Funding: Nil, **Conflict of interest:** Nil
Permission from IRB: Yes

What is already known?: Hypothermia is a common cause of excessive morbidity and mortality in neonatal period.

What this study adds?: In urban slums of Indore city incidence of hypothermia is high in home deliveries even while they are being conducted by Trained Birth Attendants. Hypothermia can fully be attributed to faulty newborn care practices.

Clinico-etiological Profile and Developmental Status of Infants Aged 1–24 months with Epilepsy

Pankaj Kumar Sahu[1] · Devendra Mishra[1] · Monica Juneja[1] · Kushagra Taneja[1]

Received: 1 November 2018 / Accepted: 25 March 2019 / Published online: 12 April 2019

Abstract

Objective To study the clinico-etiological profile of epilepsy in children aged 1–24 mo attending a tertiary-care public hospital.

Methods All infants aged 1–24 mo with epilepsy (as per International League Against Epilepsy, 2014) presenting between April 2016 and March 2017 were enrolled. Detailed history and examination were done in all children, and developmental assessment was done using Developmental Assessment Scale for Indian Infants (DASII). Electroencephalography and neuroimaging (CT/MRI) were done for all subjects.

Results Sixty children (39 males) were consecutively enrolled after informed written consent. The mean (SD) age at seizure onset was 4.3 (4.14) mo. Perinatal asphyxia (45%) and malformations of cortical development (18.3%) were the commonest etiologies. Neurological examination was abnormal in 68.3%, and a neuroimaging abnormality was present in 76% of children. Fifteen patients (25%) had West syndrome, which was symptomatic in the majority (73.3%). Developmental delay (DQ < 70) was the commonest co-morbidity (81.7%); 28.3% had profound delay. Odds of having developmental delay were 13-times higher in those with an abnormal neurological examination [OR 13.5 (2.82–64.67), $P = 0.001$], and nearly 9-times higher with abnormal neuroimaging [OR 8.9 (2.11–37.9), $P = 0.003$].

Conclusions Epilepsy in children <2 y is symptomatic in the majority, with sequelae of birth asphyxia as the commonest etiology. High prevalence of co-morbid developmental delay underscores the need for routine evaluation and early intervention in all high-risk infants.

Keywords Electroencephalography · Neuroimaging · Outcome · Seizures

Introduction

Epilepsy is the most common disabling neurological problem among children worldwide [1], and has a varying prevalence and etiological profile across the life-cycle. Onset of epilepsy prior to two-year age is more common than later in childhood [2]. It more commonly has a symptomatic cause [3–6], and poor long-term outcome with respect to seizure-control [5–7] and cognition [2–5]. A recent community-based study in this age-group in UK identified the highest incidence among Asian children [3]. Previous work from India on epilepsy in infants has either focused on a single etiology [8], on one particular epilepsy syndrome [9, 10], or on single seizure rather than epilepsy [11]. As there is a paucity of literature on infantile epilepsy from India, and because etiological correlates and types of epilepsy are likely to be different across regions [12]; the present study was conducted to delineate the clinico-etiological profile of epilepsy in infants aged between 1 and 24 mo at a public hospital in India.

Material and Methods

This descriptive study with prospective data-collection was conducted from April 2016 through March 2017, after Institutional Ethics Committee clearance. Consecutive infants aged 1 mo to 24 mo with epilepsy [13], who presented on pre-specified weekdays to the Pediatric department of authors' institution, were assessed for inclusion. Both incident and prevalent cases were enrolled after taking written informed consent from the parents. Infants diagnosed with febrile seizures were excluded.

Details regarding seizure-onset and semiology, duration of seizure, frequency, current treatment, any precipitating factors for seizures, current seizure control and current medications, antenatal/perinatal/neonatal history, and developmental status were recorded in a structured proforma. Developmental assessment was done by a single trained examiner in all children by using Developmental Assessment Scale for Indian Infants (DASII) [14]. Developmental delay was defined as the development quotient (DQ) score ≤ 70 on either the mental or motor scales [14]. Based on the development quotient, infants were classified as No delay (DQ ≥ 85), Borderline delay (DQ, 71–84), Mild delay (DQ, 50–70), Moderate delay (DQ, 35–49), Severe delay (DQ, 20–34) and Profound delay (DQ < 20).

Results of neuroimaging (either Computed tomography of head or Magnetic Resonance Imaging of brain) and electroencephalography (EEG) were recorded, if already done. For others, these were carried out at the study institution. Neuroimaging investigations were reported by a single radiologist for all infants. Evaluation for neuro-metabolic disorders (serum ammonia and lactate, blood sugar, urine for reducing substances, Tandem Mass Spectroscopy and urinary Gas Chromatography – Mass Spectrometry), and any additional investigations were carried out as per clinical suspicion.

Seizure and epilepsy classification, and etiology were labelled for each child by two experts in consultation, on the basis of the clinical history, reviewing parent-recorded video of the episode (if available), and incorporating the diagnostic data. These were re-classified as per the recent classification for the purpose of this publication [15–17]. Seizure outcome was described as 'seizure-free' (with/without antiepileptic drugs), 'controlled seizures' (<1 seizure per mo on any antiepileptic drug), and 'poorly controlled' seizures despite treatment, in last three months [18]. 'Diagnostic delay' was defined as an interval of one month or greater from second seizure to epilepsy diagnosis [19]. Birth asphyxia was labeled if there was a history of delayed cry, with either features suggestive of hypoxic-ischemic encephalopathy (lethargy, hypotonia, history of seizure) or documented low APGAR scores.

General physical examination and detailed systemic examination to document co-morbidities was done in all participants. The neurologic examination was considered abnormal if any abnormalities were evident on examination of the cranial nerves, motor system and sensory system, cerebellar functions, or gait.

All data were compiled on Excel spreadsheet and analyzed. Proportion of children with developmental delay, and in various etiological groups was calculated. The authors used a univariate analysis to compare the odds of having developmental delay in those with abnormal neuroimaging, abnormal neurological examination, and abnormal EEG. *P* value less than 0.05 was considered significant.

Results

Of the 82 infants approached, 60 infants [median age (range), 14.5 (4.8–24) mo; 39 males] were finally enrolled (Fig. 1). Seizures were observed (by a researcher or on a video-recording) in 39 (65%);15 (25%) infants were seeking medical attention for the first time. The mean (SD) age at seizure onset was 4.3 (4.14) mo. Diagnostic delay was seen in 21 (35%) infants, with the median delay (range) in presentation being 1.5 (1–18) mo. Microcephaly (30, 50%) and neurological abnormalities (41, 68.3%) were present in majority of the infants (Table 1).

Predominantly generalized seizures were present in 56.7% infants (generalized tonic-clonic, 21; myoclonic, 9; and tonic, 4), focal seizures in 11 (18.3%) and epileptic spasms in 15 (25%). Multiple type of seizures were present in 10 children. West syndrome (15), Dravet syndrome (1) and Lennox-Gastaut syndrome (1) were the epilepsy syndromes identified. Majority of the infants (42, 67%) had a structural etiology; sequelae of perinatal asphyxia (46.7%) and malformations of cortical development (18.3%) were the commonest etiologies found (Table 2). Neuroimaging had a high diagnostic yield, with an MRI abnormality being present in 76% infants (35 of 46 infants in whom MRI was done).

Complete seizure control was seen in only 22 (36.7%) infants with median (range); 2 (1–2) drugs. Remaining two-third had continuing seizures despite multiple antiepileptic drugs [median (range); 3 (1–3)]; 17/38 (44.7%) of these had daily seizures. The number of antiepileptic drugs being used in those with persisting seizures was higher than those in whom seizure were controlled [2.6 (0.74) *vs.* 1.9 (0.6); $P < 0.001$]. Non-pharmacologic modalities (Ketogenic diet, vagal nerve stimulation) for seizure management were not being used in any of the patients. The odds of having a good control of epilepsy was significantly higher among those with an unknown etiology than those with a structural etiology [OR (95% CI): 2.6 (1.44–4.87), $P = 0.004$].

Development delay (DQ ≤ 70) was the commonest co-morbidity (81.7%), with 28.3% having profound delay. Developmental delay was significantly more likely in those with an abnormal neurological examination [OR 13.5 (2.82–64.67), $P = 0.001$] or abnormal neuroimaging [OR 8.9 (2.11–37.9), $P = 0.003$]; though, not associated with an abnormal EEG ($P = 0.18$) (Table 3).

Discussion

In this descriptive study of 60 consecutively enrolled 1–24 mo-old infants with epilepsy at a public hospital in India, an underlying etiology was found for more than three-fourth infants. Perinatal asphyxia and malformations of cortical

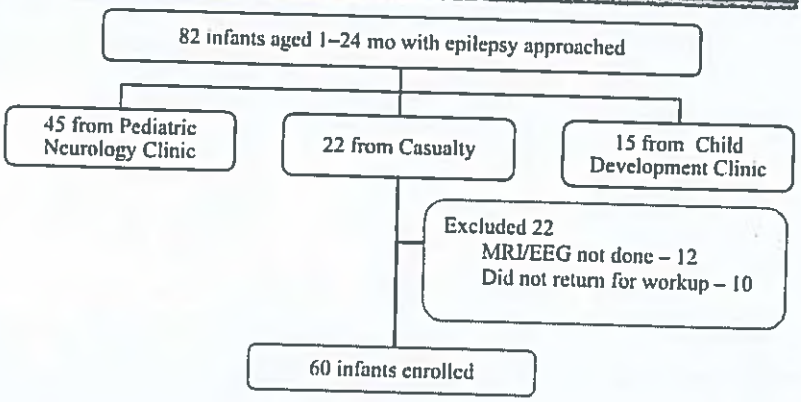

Fig. 1 Flow of participants in the study

development were the commonest etiologies, with 75% patients having an abnormal MRI. Development delay was the commonest co-morbidity, and two-third had abnormalities on neurological examination. West syndrome (WS) was the commonest epilepsy syndrome identified.

Severe delay (20–34)	8 (13.3)
Profound delay (<20)	17 (28.3)

$ Some infants had multiple abnormalities; *Delayed P wave latency in Visual evoked potentials in 17, clinically in the rest; # Delayed/absent wave V on Brain evoked response audiometry in 4, clinically in the rest; ^Few patients classified in more than one etiological category; ¥ 10 patients had multiple seizure types, classified as per predominant seizure type; € Hemiparasis-2, Paraparesis-1, Chorea-1; £ Generalized slowing-2, multi-focal discharges-4, focal abnormalities-4

Symptomatic epilepsy is reported in a high proportion (45%–82%) of infants of this age-group [3–6, 20–22]. Related finding has been the high proportion with MRI abnormalities (57%–72%) in this age-group in both community-based and hospital-based populations [3, 23]. Although, a study from this region [21] even reported 71% of CT scans

*Developmental delay: Developmental Quotient (DQ) ≤ 70 on DASII

to be abnormal, the same had been done selectively rather than in all infants. In consonance with the bulk of the literature, the current recommendations for evaluation of epilepsy in infancy also suggest MRI in all such infants [24].

Previous hospital-based studies [4, 5, 25, 26] have reported the proportion of infants with developmental delay to range between 65 and 80%, which is similar to present findings; although, a recent community-based study [3] in the UK reported subnormal cognitive functioning in around 60% of their subjects. Developmental delay in this population has been reported to be associated with abnormal neurological examination [3, 4, 27] and abnormal neuroimaging [3], similar to the present post hoc analysis. Association of developmental delay has also been reported with an abnormal neonatal [3] or current [4, 22] EEG, but authors did not find any such association, similar to other reports [27], which could have been due to the small numbers in this study.

Almost half the participants had predominantly generalized seizures, although studies have reported both generalized [21, 26, 27] or focal [20] seizures to be commoner. The proportion of children with WS in this study is in consonance with the reported 20–53% in previous studies from different regions [6, 20, 25], though lower numbers have also been reported [21, 26]. The present findings in the West syndrome sub-group were similar to the previous Indian studies [9, 10], except for an older mean age of onset in those studies, possibly due to these studies done at referral centers or the smaller numbers in the present study.

The study results are limited by its tertiary hospital-based enrolment, with majority referred from the neurodevelopment clinic. This could likely have led to enrolment of more children with associated neurodevelopmental disorders, especially global developmental delay and cerebral palsy. The generalizability of the study findings are also limited by the small numbers in this study. The authors did not collect anthropometric data, which could have helped in identifying co-existent failure to thrive in this sub-group of patients. Extensive and complete work-up of a large number of consecutively enrolled patients is the strength of the study.

This study has documented that most of the epilepsy in infants less than two years in a developing country setting is symptomatic in nature, with sequelae of birth asphyxia being the commonest etiology. This is a potentially preventable entity, likely to be amenable to better perinatal care, and early identification and management of seizures. High prevalence of co-morbid developmental delay again underscores the need for follow-up of all high-risk infants, and early identification and management of seizures. The need for further studies from different regions is highlighted so as to better elicit the various etiologies and co-morbidities of infantile epilepsy in India, especially with respect to genetic causes.

Acknowledgements The authors are thankful to Dr. Sapna Singh, Professor, Department of Radiodiagnosis, for her help in reporting on the study investigations.

Abstract

Introduction: Gaucher's disease is a hereditary disease that can be diagnosed by determination of acid β glucosidase enzyme activity on leucocytes but it's diagnosis is mostly delayed due to limited availability of test.To determine prevalence of Gaucher's disease in patients of unexplained splenomegaly and/or thrombocytopenia using dried blood spot filter test.**Methodology:** This prospective cross sectional study was conducted after approval from Institutional ethical committee in 222 subjects, assuming 3.6% prevalence of the disease among unexplained cases of splenomegaly with 95% confidence interval, 0.05 α error, 80% power and with an absolute allowable error of 2.5%. After implementation of the diagnostic algorithm, samples from the patients were collected on dried blood pot filter paper and sent for analysis. Patients who tested positive by screening test were confirmed through mutational analysis done from the same sample. Data was expressed as mean, proportions and percentages. Mann Whitney test,Chi square test and Fisher's exact test were used for analysis.**Results:**The prevalence of Gaucher's disease in our study population was 2.7% (CI 0.54 to 4.86) with the odds ratio for gender calculated as 3(95% CI 0.344 to 26.134).**Conclusion:**The results of this study show that the use of an appropriate diagnostic algorithm and DBS filter test facilitate early diagnosis and management of a rare disease, thereby saving a lot of medical resources while simultaneously improving the quality of life in patients.

Key-words:Gaucher's disease, Dried blood spot filter test, Splenomegaly, Thrombocytopenia.

Introduction

Gaucher's disease(GD), the most common lysosomal storage disorder, is an autosomal recessive hereditary disease due to the congenital deficiency of lysosomal enzyme acid β-Glucosidase. It leads to accumulation of non-degraded glycosphingolipids (gluco cerebroside) in the macrophagic cells of the reticulo-endothelial system. The disease incidence in patients with Ashkenazi Jewish heritage varies from 1 in 450 to 1 in 1000, while in the rest of populations the incidence is estimated at 1:40000 to 1:60000.[1,2] Gaucher's disease is progressive and if not treated, it may lead to increased morbidity and mortality due to liver failure, pulmonary hypertension, skeletal complications, haemorrhage and sepsis.[3] Splenomegaly and thrombocytopenia are the two most typical and frequent manifestations of GD.[4] Though, GD can be easily diagnosed by determination of acid β glucosidase enzyme activity (<30% compared to healthy subjects) on leucocytes, taken from a peripheral blood sample, it's diagnosis is mostly delayed due to availability of test only at limited centres.[5]We hypothesised that a novel screening method of dried blood spot filter test can be used to screen Gaucher's disease in patients with unexplained splenomegaly and/or thrombocytopenia after implementation of an appropriate diagnostic algorithm. The primary aim of this study is to determine the prevalence of Gaucher's disease in patients of unexplained splenomegaly and/or thrombocytopenia using dried blood spot filter test and appropriate diagnostic algorithm. This method will eliminate the diagnostic delay, creating opportunities for the patient to receive treatment with enzyme replacement therapy(Imiglucerase) in the reversible phase of the disease and hence, reducing overall morbidity.[6]

Materials and Methods

This cross sectional observational study was carried out in the department of pediatrics at our institute after approval from institution's ethical committee. A written and informed consent was taken from the patient's relatives after explaining the procedure to the patient. Assuming 3.6% prevalence of GD among unexplained cases of splenomegaly, sample size was calculated to be 222 with 95% confidence interval, 0.05 α error, 80% power, with an absolute allowable error of 2.5%.[7]

Inclusion criteria comprised of patients with unexplained splenomegaly and persistent thrombocytopenia(Table 1).

Exclusion criteria was defined as the cases where causes of splenomegaly and/or thrombocytopenia have been ascertained e.g. haematological malignancies, splenomegaly due to portal hypertension, haemolytic anaemia, haemoglobinopathies, acute and chronic infections.After implementation of Gaucher's disease diagnostic algorithm proposed by Mistry et al, samples from the patients were collected on Dried Blood Spot (DBS) filter paper and sent for analysis of β-glucosidase enzyme levels. The normal reference range for β-glucosidase enzyme activity, estimated by fluorometric assay on DBS samples was taken as 2.3 – 14.1 nmol/ml/hr, and patient range as 0 – 2 nmol/ml/hr.[8] Level of chitotriosidase enzyme was also measured in the patients with normal range considered as <150 nmol/ml/hr. Patients who tested positive by

screening test were confirmed through mutational analysis done from the same sample.

Statistical Analysis was done with SPSS-16 and MS-Excel. Data was expressed as mean, proportions and percentages. Mann Whitney U test was used to calculate difference of means between two groups. Chi square test and Fisher exact test were used to demonstrate association between two variables, as appropriate.

Table 1: Inclusion criteria

S.no	Inclusion criteria	
1.	Unexplained splenomegaly	Clinically palpable spleen ≥ 2 cm from the costal margin
		Splenomegaly diagnosed by Ultrasonography
2.	Persistent thrombocytopenia	Platelet count<100,000/mm^3 on 2 occasions at least 4 weeks apart alongwith bone pain or Hemogobin<10g/dl
		Platelet count<100,000/mm^3 with history of splenectomy

Results

Two hundred twenty two patients with unexplained splenomegaly and/or thrombocytopenia were enrolled in this study. Out of 222 patients, 129 patients had both splenomegaly and thrombocytopenia, 68 had only splenomegaly while 25 had only thrombocytopenia. Among the 222 patients, 6 had low(< 2 nmol/ml/hr) levels of β-glucosidase enzyme level and high chitotriosidase level (>150 nmol/ml/hr). GD patients had significant growth retardation as compared to other patients included in the study(p value- 0.005). Average Spleen size of GD patients was significantly more than other patients(p value – 0.001). Platelet count was found to be on lower side in GD patients (p value- 0.045). GD patients had higher Serum iron than other patients (p value- 0.036). On performing ultrasongraphy, GD patients had increased liver and spleen size, with p value of 0.002 and 0.016, respectively.(Table 2)

Discussion

Gaucher's disease is the most common lysosomal storage disorder with the estimated prevalence of 1:60,000 to 1:40,000 in non-Ashkenazi jews population. There have been no prevalence studies in India, so the actual prevalence is not yet known. Some studies suggest overall prevalence to be 1:105, while others suggest higher number depending on the demographic profile.[9,10] As GD is a rare disease, involving multiple organs with variable clinical manifestation, it is accompanied by delayed diagnosis and delayed commencement of enzyme replacement therapy. Only twenty percent haematologist/oncologist considers GD in the differential diagnosis of a patient with a history of anaemia, thrombocytopenia, hepatomegaly, splenomegaly and bone pain.[11] Many a complex algorithm have been proposed for screening of patients with GD. Screening algorithm proposed by Maja et al uses five indicators i.e. skeletal erlenmeyer flask(EF) deformity, growth retardation, strabismus and/or oculomotor palsy, serum ferritin levels and tartrate resistant acid phosphatase(TRAP) levels.[12] Serum ferritin or TRAP levels are not part of routine laboratory investigations and not many

GD patients present with characteristic skeletal EF deformity, strabismus and oculomotor palsy. Therefore, relatively simple diagnostic algorithm described by Mistry et al, which uses splenomegaly and thrombocytopenia for screening was used in our study. The diagnostic algorithm proposed by Mistry et al has already been successfully applied in previous studies.[7]

The gold standard for diagnosis of Gaucher's disease is acid β-glucocerebrosidase enzyme assay in blood leucocytes but its regular use is hampered by its inaccessibility. So, we used DBS filter test for diagnosis of GD. Though DBS filter test is not the gold standard but it has been well validated in previous studies for the diagnosis of GD.[8]The prevalence of GD in our study population i.e. patients with unexplained splenomegaly and/or thrombocytopenia, was 2.7% (CI 0.54 to 4.86) with the odds ratio for gender calculated as 3(95% CI 0.344 to 26.134). There were 3 males and 1 female. Our results were similar to the study conducted by Motta et al who found the prevalence of GD in the same patient group to be 3.6% (CI 95% 1.4–7.2) with 5 females and 2 males.[13] In our study, the mean age at presentation was 55.27 ± 5.75 months (4.6 ± 0.475 years) while the mean age of diagnosis of GD was 57.60 ± 2.26 months (4.8 ± 0.188 years). Lei et al had also observed similar findings in their study. Out of 73 children, four (three boys and one girl) were diagnosed with GD, with a median age of 1.5 years, and the prevalence in that specific population was ascertained to be 5.5% (1.5-13.4%). [8,14,15]In our study, 100% of GD cases had hepatosplenomegaly (66.67% had moderate splenomegaly and 33.33% had severe splenomegaly) and thrombocytopenia. 83.3% of patients with GD had anaemia, 66.67% had growth retardation, 33.3% had bone pain but none had radiologic bone disease. These findings were consistent with ICGG Registry as 66.67% GD cases in our study were younger than 6 year. Among the six GD patients in our study, thrombocytopenia and anaemia were observed more frequently when compared with the ICGG registration which showed 50% of children with severe or moderate platelet count, and about 40% with anaemia.[4] Genotype data from the ICGG Registry indicate that four common mutations constitute 72% of all GD alleles: N370S, L444P, IVS2+1, and 84GG.[4] Depending on the allele involved the presentation and the average age of diagnosis is highly variable. At the time of diagnosis, patients with the L444P/L444P genotype had median age of 1 year. All other allele groupings had a median diagnosis age ranging from 3 to 7 years. In our study, 50% (3) had L483P/L483P genotype, 33.33% (2) had L444P/L444P genotype and 16.67% (1) had L444P/A456P genotype. 2 out of 3 L444P genotype had neurological manifestation and 1 out of 3 L483P mutation had neurological manifestations.(Table 3)

Table 3: Comprehensive evaluation of six patients with positive DBSresult

S.no.	Chitotriosidase level	β glucosidase enzyme level	Mutation Analysis*
Patient 1	239	0.46	[L444P]+[L444P]
Patient 2	228.52	1.01	[L444P]+[A456P]
Patient 3	1051.1	1	[L444P]+[L444P]
Patient 4	789	1.63	[L483P]+[L483P]
Patient 5	1041.26	1.9	[L483P]+[L483P]
Patient 6	1232.67	0.9	[L483P]+[L483P]

**The mutations are described according to the traditional amino acid residue numbering*

The relevance of the combined approach based on Mistry et al's algorithm and the use of DBS filter test to assess the β-glucosidase enzyme activity is that it can be made easily accessible, permitting earlier diagnosis and management. Although the number of GD cases in our study was small, our findings expect paediatricians to be increasingly suspicious for diagnosis of GD in children with thrombocytopenia and/or anaemia, especially those accompanied with hepatosplenomegaly.There should be a high index of suspicion in order to diagnose rare genetic disorders in children presenting with common clinical manifestation. The diagnostic algorithm was proved to be appropriate to make an early diagnosis of GD patients with mild symptoms or atypical symptoms and avoid diagnostic delay. DBS filter test is convenient for preparation, storage and transport, and can effectively screen GD patients, hence it can be used as a preliminary screening method for GD diagnosis. These results show that the use of an appropriate diagnostic algorithm and a simple, relevant diagnostic method, such as DBS filter test, are important tools to facilitate early diagnosis and management of a rare disease, thereby saving a lot of medical resources while simultaneously improving the quality of life in patients.

International Journal Of Research In Medical Sciences

International Journal of Research in Medical Sciences (IJRMS) is an open access, international, peer-reviewed general medical journal. The journal's full text is available online at http://www.msjonline.org. The journal allows free access to its contents. International Journal of Research in Medical Sciences is dedicated to publishing research in medical science from all disciplines and therapeutic areas of medical science or practice. The journal has a broad coverage of relevant topics across medical science or practice. International Journal of Research in Medical Sciences (IJRMS) is one of the fastest communication journals and articles are published online within short time after acceptance of manuscripts. The types of articles accepted include original research articles, review articles, editorial, medical news, case reports, adverse drug reactions, short communications, correspondence, images in medical practice, clinical problem solving, perspectives and new drug updates. It is published monthly and available in print and online version. International Journal of Research in Medical Sciences (IJRMS) complies with the uniform requirements for manuscripts submitted to biomedical journals, issued by the International Committee for Medical Journal Editors.

ABSTRACT

Background: To study the occurrence of hypocalcaemia in neonates with physiological unconjugated hyperbilirubinemia after 48 hours of phototherapy or at the end of phototherapy, in case duration of phototherapy was less than 48 hours.
Methods: This prospective study was conducted on 100 term neonates (61 males and 39 females) admitted to Neonatal intensive care unit of Teerthankar Mahaveer Medical College, Moradabad with unconjugated hyperbilirubinemia and requiring phototherapy. Total Serum bilirubin levels and serum calcium levels were checked before and after phototherapy. Neonates were assessed for clinical features of hypocalcemia i.e. jitteriness, irritability/excitability, lethargy and convulsions.
Results: After phototherapy, there was hypocalcemia in 35.0% neonates. The difference between pre and post phototherapy serum calcium levels were found to be statistically significant ($p < 0.001$). 2.86% of neonates developed jitteriness among those who had hypocalcemia. Hypocalcemia was more in subjects who received phototherapy for longer duration.
Conclusions: Hypocalcaemia is a common complication of phototherapy. Therefore, calcium supplementation should be done in all neonates undergoing phototherapy.

Keywords: Hyperbilirubinemia, Hypocalcemia, Phototherapy, Term neonates

INTRODUCTION

Neonatal jaundice is a common and benign problem in neonates. Jaundice is observed during first week of life in approximately 60 % of term neonates and 80 % of preterm neonates.[1] Untreated severe unconjugated hyperbilirubinemia is potentially neurotoxic.

Phototherapy is one of the routine method for management of hyperbilirubinemia. However, it is not a harmless intervention. It can produce adverse effects such as dehydration, temperature instability, skin rashes, loose stools, retinal damage, hypocalcemia, bronze baby syndrome, redistribution of blood flow and genotoxicity. It causes photo oxidation of bilirubin into water soluble or less lipophilic colorless form of bilirubin which is readily excreted in bile, feces and urine.

Hypocalcemia is one of the lesser known adverse effects of phototherapy. It is defined as total serum calcium concentration of <7mg/dl (1.75mmol/L) in preterm and serum calcium <8mg/dl (2mmol/L) in term neonates. It can cause serious complications like neuromuscular irritability, myoclonic jerks, jitteriness, convulsion, cyanosis, apnea and laryngospasm.[2] Cardiac

manifestations like tachycardia, heart failure, prolonged QT interval and decreased contractibility are also seen due to hypocalcemia.[2]

Aims and objectives was to study the occurrence of hypocalcaemia in neonates with physiological unconjugated hyperbilirubinemia after 48 hours of phototherapy or at the end of phototherapy, in case duration of phototherapy is less than 48 hours.

METHODS

This study was conducted in Neonatal Intensive Care Unit (Department of Pediatrics) at Teerthankar Mahaveer Medical College and Research Centre, Moradabad. Ethical approval for the study was obtained from the Institutional Ethical Review Committee.

It was Hospital based prospective study and 100 term neonates was there.

Inclusion criteria

Full term neonates (37 completed weeks to 41 weeks) with unconjugated hyperbilirubinemia requiring phototherapy.

Exclusion criteria

New borns

- To a diabetic mother
- With onset of jaundice within 24 hrs of age
- With perinatal asphyxia (Apgar <4 at 1 minute of birth)
- Whose mother had history of taking Anti-convulsants
- Fed with cow's milk
- Who had exchange transfusion
- With jaundice lasting more than 14 days of life
- With sepsis
- With jaundice having hypocalcemia prior to the start of phototherapy
- Babies born with apparent major congenital anomalies
- ABO incompatibility.

Written informed consent was taken from parents/guardians of all eligible subjects in their preferred language. Complete maternal history was taken and maternal risk factors like hypertension, diabetes mellitus, oligohydramnios, anaemia, epilepsy, fever, any rash, any drug intake during pregnany other than iron and folic acid supplementation were ruled out.

Complete history and physical examination was carried out in all neonates included in the study. Dermographic and clinical variables were recorded. It included birth weight, sex, gestational age, mode of delivery, time of appearance of icterus in hours, maternal blood group and Rh status, baby blood group and Rh status, anthropometric measurements (weight, length and head circumference) of infant at the time of admission and duration of phototherapy.

Total serum bilirubin (TSB), serum calcium, serum albumin, G6PD, Direct Coombs Test (DCT), Reticulocyte count and thyroid profile were sent in all cases. TSB and Serum calcium levels before and at the end of phototherapy were recorded. The first sample was considered as control. Hypocalcemia was considered as total serum calcium of <8mg/dl. Neonates were clinically assessed for features of hypocalcemia.

A conventional phototherapy equipment, containing four blue light fluorescent lamps with wavelengths of 410-470nm, was placed at a distance of 25-35cm from the skin surface of neonates under standard protocol with eyes and genitals completely covered. The irradiance during phototherapy was measured and maintained consistently at 15μW/cm²/nm at the level of infant's skin.

Statistical analysis

Data were analysed using SPSS version 17 software. Descriptive statistical analysis was done and continuous variables were described as mean and standard deviation and categorical variables in number and percentage. Students paired t test and unpaired t test had been used to assess continuous variables for pair matched samples with 95% confidence limit. p value less than 0.001 was considered statistically significant.

RESULTS

The study group included 100 neonates, 61 boys (61.0%) and 39 girls (39.0%), with mean gestational age of 38.16±0.95 weeks and mean birth weight of 2.66±0.33 kilograms. 57.0% neonates were delivered by normal vaginal delivery and 43.0% by lower segment caesarean section. Mean time of appearance of icterus and duration of phototherapy was 102.60±48.10 hours and 42.48±10.15 respectively (Table 1).

Table 1: Dermographic features of newborns.

Variable	Mean and number (%)
Gestational age (weeks)	38.16±0.95
Birth weight (kilograms)	2.66±0.33
Time of appearance of icterus (hours)	102.60±48.10
Duration of phototherapy (hours)	42.48±10.15
Type of delivery	
Normal vaginal delivery	57 (57.0%)
Lower segment caesarean section	43 (43.0%)

Mean total serum bilirubin levels before and at the end of phototherapy was 19.48±2.78mg/dl and 11.18±3.11mg/dl

respectively. Mean serum calcium levels before phototherapy was 9.14±0.78mg/dl and it reduced to 8.53±0.77mg/dl after phototherapy. It was found that there was significant reduction ($p<0.001$) in mean total serum bilirubin and mean serum calcium levels after phototherapy as compared to pre phototherapy levels (Table 2).

Table 2: Comparison between mean total serum bilirubin and serum calcium levels before and after receiving phototherapy.

Test	Admission time	After phototherapy	p-value
Total serum bilirubin (mg/dl)	19.48±2.78	11.18±3.11	0.000
Total serum calcium (mg/dl)	9.14±0.78	8.53±0.77	0.000

Serum calcium levels after phototherapy was >8mg/dl in 65.0% of subjects and hypocalcemia i.e. serum calcium levels <8mg/dl was noted in 35.0% of subjects (Table 3, Figure 1).

Table 3: Descriptive data of serum calcium levels post phototherapy.

Variable	N=100
Hypocalcemia (<8mg/dl)	35/100 (35.0%)
Normal calcium (>8md/dl)	65/100 (65.0%)

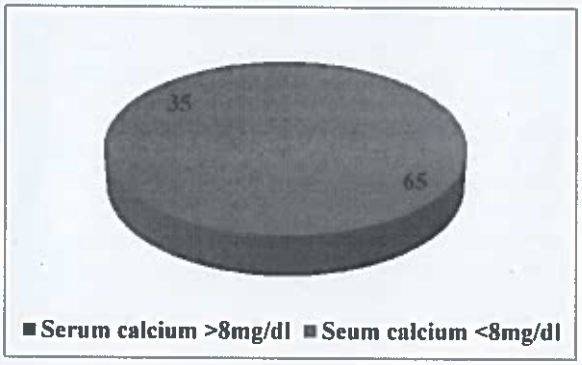

Figure 1: Incidence of hypocalcemia in term neonates after phototherapy.

Table 4: Descriptive data of symptoms among hypocalcemic cases post phototherapy.

Variable	N=35/100
Symptomatic (jitterriness)	1/100 (2.86%)
Asymptomatic	34/100 (97.14%)

Out of 35 subjects who had hypocalcemia, only one subject (2.86%) was symptomatic and developed jitteriness. Rest of the subjects (97.14%) were asymptomatic (Table 4). Also, incidence of hypocalcemia was more in neonates who received phototherapy for 48 hours (77.1%) as compared to neonates who received phototherapy for 24 hours (22.9%) (Table 5, Figure 2).

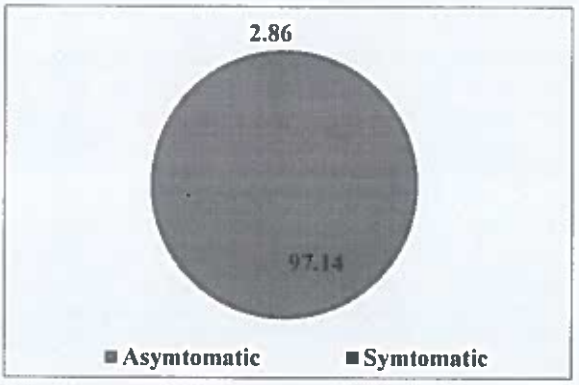

Figure 2: Incidence of symptomatic hypocalcemia.

Table 5: Incidence of hypocalcemia based on the duration of phototherapy.

	Hypocalcemia	Percentage
24 hours	8	22.9%
48 hours	27	77.1%
Total	35	100%

DISCUSSION

Phototherapy is an appropriate and commonly used measure to reduce indirect bilirubin level in newborns. Romagnoli et al was the first to suggest the association of hypocalcemia in newborn following phototherapy.[3]

The mechanism of hypocalcemic effect of phototherapy was reported by inhibition of pineal gland via transcranial illumination, resulting in decline of melatonin secretion which blocks the effect of cortisol on bone calcium. Cortisol has a direct hypocalcemic effect and increases bone uptake of calcium and induces hypocalcemia.[4]

In this study, there was a significant decrease in serum calcium levels after 48 hours of phototherapy ($p<0.001$). The mean serum calcium in this study after phototherapy was 8.53±0.77mg/dl. This was in correlation with studies done by Bahbah et al (8.58±0.76) and Singh et al (8.42±1.19).[5,6]

In an Iranian study, 7.5% neonates developed hypocalcemia after receiving phototherapy.[7] In our study, hypocalcemia was observed in 35.0% of neonates after phototherapy. Shrivastva et al, also observed hypocalcemic effect of phototherapy in 30.0% of term neonates.[8] Sethi et al, observed hypocalcemia in 75% of term neonates after phototherapy.[9]

None of the hypocalcemic neonates were clinically symptomatic in studies by Tehrani et al and Reddy et al.[7,10] In our study, symptomatic hypocalcemia was

observed in 2.86% of neonates which was similar to studies by Yadav et al and Sethi et al who also observed symptomatic hypocalcemia in term neoantes.[11,9] Bahbah et al. observed jitteriness in 14% and convulsions represented 10% of hypocalcemic cases.[5]

In a study by Reddy et al. the incidence of hypocalcemia was 18.8% when duration of phototherapy was >48 hours as compared to duration <48 hours (10.9%).[10] Out of total 35 cases of hypocalcemia in our study, incidence of hypocalcemia was more in neonates who received phototherapy for 48 hours (77.1%) as compared to neonates who received phototherapy for 24 hours (22.9%).

CONCLUSION

Phototherapy induced hypocalcemia is a significant problem. Careful estimation of calcium status should be done before starting and during phototherapy for neonatal jaundice and close monitoring of neonates for signs of hypocalcemia should be done. Calcium supplementation can be considered as prophylaxis in neonates undergoing phototherapy.

Abstract

Background: Diagnosis of celiac disease in children suffering from severe acute malnutrition without duodenal biopsy or HLA typing is a dilemma. The objective of this study was to study the response to gluten free diet in sero-positive Celiac Disease children suffering from severe acute malnutrition in age group 1-5 years. **Methods:** This prospective, observational, hospital-based study was conducted at MTC of tertiary care medical college hospital of southern Rajasthan from Feb. 2019 to Jan. 2020. Total 220 children with SAM were enrolled and screened for celiac disease on the basis of tissue tTg-IgA/IgG serology. Seropositive cases were kept on gluten free diet for short period of time and observed for the resolution of symptoms and improvement in growth, monitored by anthropometry on discharge and follow up visit. **Results:** Mean weight gain (gm/kg/day) on follow up was 3.87±3.49 in seropositive and 1.88±3.79 in seronegative cases (P-value<0.05). Mean weight gain was 6.43±3.28gm/kg/day in only tTg-IgA positive and 3.04±2.95 gm/kg/day in only tTg-IgG positive cases (P-value-<0.05). The mean weight gain in strictly gluten free adherent sero-positive cases was 4.89±2.97 gm/kg/day while in gluten free non-adherent patients it was -0.49±1.70 (P-value <0.001). Mean weight gain in probable (tTg-Ig-A <10 times ULN) and presumptive (tTg-IgA >10 times ULN) Celiac disease were 3.44±3.73 and 5.44±3.78, respectively without statically significant difference (P-value >0.05).**Conclusions:** In situations where facility of duodenal biopsy and or HLA DQ2/DQ8 typing is not available, resolution of symptoms and improvement in growth on gluten free diet confirms the diagnosis of celiac disease.

Keywords: Celiac disease, Gluten free diet, Tissue trans-glutaminase, Severe acute malnutrition.

Introduction

Celiac disease is emerging as a public health problem in India. Almost 6-8 million Indians are estimated to have celiac disease.[1] A massive increase in the number of patients with celiac disease is expected now and in the subsequent decade in India because of increasing awareness and availability of diagnostic facilities. Celiac disease is a common cause of malabsorption in the children and adults. It is characterized by an enteropathy and lifelong intolerance to gluten initiated by ingestion of gliadin related prolamines from cereals such as wheat, barley and rye in genetically susceptible individual.[2] As per NFHS-4 (2015-16) severe acute malnutrition afflicts nearly 7.5% of children below 60 months of age in India.[3] Several studies had reported high prevalence of celiac disease in north India particularly Punjab and Rajasthan in general population and children.[4-7] The clinical features of severe acute malnutrition (SAM) often overlap with the common manifestations of celiac disease such as diarrhea, failure to thrive, vomiting, abdominal distension, anemia, weight loss and irritability.[8,9] The diagnosis of celiac disease is based on clinical features, celiac serology followed by confirmation by duodenal biopsy and or HLA DQ2/DQ8 typing.[10] Facility of upper GI endoscopy and duodenal biopsy or HLA typing is available at very few centres and are expensive and most of the time not possible.This study was designed to diagnose the celiac disease in SAM children of 1-5 years of age group on the basis of celiac serology and observe the response to gluten free diet in celiac seropositive patients.

METHODS

The present study was an observational hospital based prospective study, carried out at malnutrition treatment center (MTC) at ananta institute of medical science & research center Rajsamand, Rajasthan. The study was conducted from February 2019 to January 2020. Prior approval was sought from institutional ethical committee of medical college. After written informed consent from both the parents total 220 children of either gender admitted in MTC, fulfilling the inclusion criteria, were enrolled for the study. Diagnosis of severe acute malnutrition was based on WHO criteria for severe acute malnutrition.

Inclusion criteria

- All the SAM children (meeting the WHO criteria for SAM) of age 1 to 5 years admitted in MTC and who are exposed to gluten containing diet.

- Parents given informed and written consent to enroll in the study.

Exclusion criteria

- Seriously sick SAM children admitted in PICU.
- Patients with secondary malnutrition-known c/o chronic medical or surgical disorders leading to malnutrition-congenital heart diseases with CHF, chronic renal failure, hepatic cholestasis, thyrotoxicosis, isolated childhood diabetes mellitus, HIV, childhood tuberculosis, cerebral palsy, genetic/ chromosomal syndromes, inborn errors of metabolism (IEM), malignancies, surgical resection of intestine etc
- Patients with known celiac serology
- Patients who were not exposed to gluten containing diet
- Parents not given for consent.

Celiac disease sero-positivity was accessed by screening for tissue transglutaminase IgA (tTg-IgA) and IgG (tTg- IgG) antibodies by enzyme linked immuno-sorbent assay (ELISA) method (Aeskulisat tTg-A/tTg-G new generation antigen-based kit by Aesku. Diagnostics Gmbh and Co. Kg). As per manufacturer manual of the kit, cut off value for sero-positivity for tTg-IgA/IgG was>18U/ml. Celiac Disease status was labeled according to titer of tTg-IgA and tTg-IgG as shown in Table 1.All the celiac disease seropositive patients were kept on strict gluten free diet after proper counselling. After admission anthropometric measurements and symptomatic improvement were recorded on discharge and on follow up visit.

Statistical analysis

All the collected data were managed and analysed with standard software (SPSS version 20). P-value of <0.05 was considered significant.

Table 1: Celiac disease status according to titer of tTg-IgA and tTg-IgG.

Celiac disease status	tTg-IgA Titre (Unit/ml)*	tTg-IgG Titre (Unit/ml)*
No celiac disease	≤18	≤18
Probable celiac disease (<10 times of ULN)	>18 - up to 180	>18
Presumptive celiac disease (10 times of ULN)	>180	

* Normal Range for tTg-IgA and tTg-IgG: 12-18 unit/ml (as per manufacturer manual of the kit); ULN- Upper limit of normal.[11]

Results:

Table 2: Gender wise distribution of cases.

Gender	No.	Percentage
Male	130	59.09
Female	90	40.91
Total	220	100.00

Out of total 220 enrolled cases 130 (59.09%) were male and 90 (40.91%) were female. The male to female ratio was 1.44:1 (Table 2).

Table 3: Mean weight gain at follow-up.

Sero-positivity status	Weight gain (gm/kg/day) at follow-up	
	Mean	SD
Seronegative	1.88	±3.79
Seropositive	3.87	±3.49

P-value>0.05

Seropositive celiac disease (either tTg-IgA or IgG or both IgA and IgG) was positive in 60 (27.28%) cases out of 220 enrolled cases of severe acute malnutrition. Mean weight gain (gm/kg/day) on follow up was (3.87±3.49) in seropositive group and in seronegative was 1.88±3.79. This difference was statistically significant (P- value<0.05) (Table 3).

Table 4: Mean weight gain at follow-up according to tTg-IgA titre levels.

Levels of tTg- IgA titre (U/ml)	Mean weight gain (gm/kg/day) at follow-up	
	Mean	SD
>18 up to 180	3.44	3.73
>180	5.79	3.78

P-value >0.05

Mean weight gain (gm/kg/day) on follow up in both tTg-IgA positive cases was statically insignificant (P-value>0.05) (Table 4).

Table 5: Mean weight gain at follow-up in only tTg- IgA v/s only tTg -IgG seropositive cases.

Seropositivity status	Mean weight gain(gm/kg/day)	
	Mean	SD
Only tTg-IgA positive (n=8)	6.43	3.28
Only tTg-IgG positive (n=7)	3.04	2.95

P-value <0.05

Mean weight gain (6.43±3.28) was more in only tTg-IgA positive compared to tTg-IgG positive group (3.04±2.95). This difference was statically significance (P-value-<0.05) (Table 5).

Table 6: Follow up status in cases.

Follow-up status	Seronegative group (n=80)	%	Seropositive group (n=30)	%
Follow-up	60	37.50	42	70
Follow-up failure	100	42.50	18	30

After discharge follow-up was 70% (42 out of 60) in seropositive group and 37.5% (60 out of 160) in seronegative group (Table 6).

Table 7: Gluten free diet adherence status and mean weight gain in seropositive cases on follow-up.

Gluten free diet adherence status	No.	%	Mean weight gain (gm/kg/d)	SD	P- value
Strictly Followed Gluten free diet	34	80.95	4.89	±2.97	<0.001 (HS)
Not Followed Gluten free diet	8	19.05	-0.49	±1.70	

Most of the seropositive patients 34 (80.95%) were adhered to gluten free diet as per counselling at discharge. While 8 (19.05%) were not adhered to gluten free diet (Table 7).

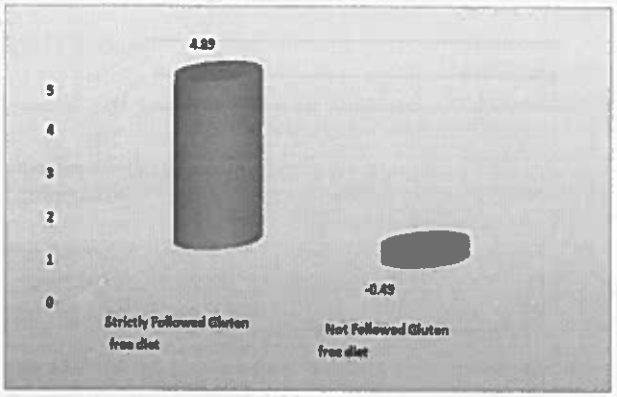

Figure 1: Mean weight gain (gm/kg/day) in gluten free diet adherent and non-adherent cases.

Mean weight gain (gm/kg/day) in strictly gluten free adherent sero-positive cases was 4.89±2.97 while in gluten free non-adherent patients it was -0.49±1.70. This difference of mean weight gain in gluten free adherent and non-adherent was statistically highly significant (P- value <0.001) (Table 6 and Figure1).

Discussion

Celiac disease and severe acute malnutrition in children share common clinical features. Confirmatory diagnosis of celiac disease is based on serology followed by duodenal biopsy or HLA DQ2/DQ8 typing.In situations where availability of Pediatric Gastroenterologist and facility of upper GI endoscopy for duodenal biopsy in small sick children (less than 5 years) is not possible or available and HLA typing is also not available/feasible then gluten free diet may be tried in celiac positive serology patients and observed for improvement in anthropometry and resolution of symptoms.In present study, authors kept the celiac seropositive patients suffering from SAM on gluten free diet and observed the response. On follow up the mean weight gain (gm/kg/day) in sero- positive cases was more in comparison to seronegative cases (P-value <0.05). This shows good response to gluten free diet in sero-positive cases and confirms the diagnosis of celiac disease in these cases.The mean weight gain on follow up was more in presumptive celiac disease sero-positive cases (5.79±3.78 gm/kg/day) in comparison to probable celiac disease sero-positive cases (3.44±3.73gm/kg/day). Although the mean weight gain was more in presumptive celiac Disease sero-positive cases but the difference of weight gain between probable and presumptive celiac sero- positive cases was statistically not significant (P- value>0.05). This suggests that response to gluten free diet is similar in tTg-IgA titre <10 and >10 times of ULN cases.So, we should not wait for to rise the tTg antibody titres>10 times of ULN and start the gluten free diet at lower level if clinical features are also suggestive of celiac disease and observe the response to gluten free diet.Mean weight gain in only tTg-IgA seropositive cases was more (6.43±3.28gm/kg/day) in comparison to only tTg- IgG sero-positive cases which was statistically significant (P-value <0.05). Comparatively lower weight gain in only tTG-IgG sero-positive cases may be because of underlying IgA deficiency leading to recurrent gastrointestinal infections and another reason may be more damage to intestinal epithelium requiring more time to regenerate and slow response to gluten free diet.In present study most of patients (93%) discharged successfully but follow-up was 70% (42 out of 60) in seropositive group and rest 30 % of seropositive cases could not be followed and follow up failure was reported for these cases. This showed that more emphasis should be given on follow up counseling in addition to dietary counseling at the time of discharge.On follow up visit after discharge authors observed that most of the sero-positive patients were well adhered to gluten free diet as per dietary counselling at the time of discharge.The mean weight gain was more in strictly adhered to gluten free diet as compared to non-adhered to gluten free diet (P-value <0.001). This is suggestive of importance of adherence to gluten free diet in Celiac disease.Other study conducted by Bhadada S et al, in short stature children age 10-15 years were screened for Celiac disease and observed that all patients showed good response in growth velocity (cm/year) to a gluten-free diet, but no other study was conducted so far to see the response to gluten free diet in celiac disease in children suffering from severe acute malnourished children in age group 1-5 years.[13]

Conclusion

Gluten free diet may be started empirically in sero- positive patients for short period of time assuming presumptive celiac disease and observed for resolution of signs/symptoms and improvement in growth.If there is rapid resolution of signs/symptoms and significant improvement in growth, confirmed celiac disease may be considered and gluten free diet continued for life long. There is no need for duodenal biopsy or HLA DQ2/DQ8 typing in these patients.If sero-positive patients with good adherence to gluten free diet do not show neither resolution of symptoms nor improvement in growth, then gluten free diet may be stopped and evaluated further to find the etiology.

Abstract

Introduction: Celiac disease (CD) may be an underlying cause of malnutrition.

Aim: The objective of this study was to find out the seroprevalence of CD in children suffering from severe acute malnutrition (SAM) in age group of 1–5 years.

Materials and Methods: This was a prospective, observational, hospital-based study carried out at Malnutrition Treatment Centre attached with the ananta institute of medical science & research center Rajsamand, Rajasthan, from February 2019 to January 2020. A total of 220 children with SAM were enrolled and screened for CD on the basis of celiac serology (tissue transglutaminase [tTg]-immunoglobulin A/G [IgA/IgG]).

Results: Celiac serology was positivity in 60 (27.28%) cases; out of total 60 seropositive cases, 28 (46.66%) cases were seropositive for both tTg-IgA and IgG, while only tTg-IgA and only tTg-IgG were positive in 18 (30%) and 14 (23.33%) cases, respectively. Mean serotiter of serum tTg-IgA and IgG in seropositive cases was 134.01±198.74 and 49.05±25.74 unit/ml.

Conclusions: High seroprevalence of CD in SAM should be taken as alert as CD may be an underlying cause and responsible for malnutrition. These children should be screened by celiac serology (tTg-IgA/IgG) to rule out CD.

Key words: *Celiac disease, Seroprevalence, Severe acute malnutrition*

Introduction

Celiac disease (CD) is defined as a permanent intolerance to ingested gluten (the protein components of wheat, barley, and rye). The intolerance to gluten results in immune-mediated damage to the mucosa of the small intestine characteristically inducing villous atrophy and crypt hyperplasia that resolves with the removal of gluten from the diet [1]. CD is one of the most common lifelong disorders in countries populated by individuals of European origin, affecting approximately 1% of the general population worldwide [2].The exact incidence of CD in India is not known, but the disease is estimated to constitute 26% of all cases of malabsorption syndrome or 4–5% of all chronic diarrheas. In PGI, Chandigarh, 20–40 new patients are seen every year and CD constitutes 7% of indoor admissions and about 5% of the patients attending pediatric gastroenterology clinic [3]. Indian Council of Medical Research task force commissioned community- based study completed recently at three sites in India, the pooled prevalence of CD and potential CD, respectively, were 8.53/1000 and 3.70/1000 in northern (Haryana), 4.66/1000 and 3.92/1000 in northeastern (Assam), and 0.11/1000 and 1.22/1000 in the southern (Tamil Nadu) study sites [4]. This is clearly an area for further inquiry and evidence generation.Diagnosis of CD is based on the combination of clinical features with a high index of suspicion, celiac serology, duodenal biopsy, and/or human leukocyte antigen (HLA)-DQ2/DQ8 typing [5]. The clinical features of severe acute malnutrition (SAM) often overlap with the common manifestations of CD such as diarrhea, failure to thrive, vomiting, abdominal distension, anemia, and weight loss [6,7]. As per the National Family Health Survey-4 (2015–2016), SAM affects nearly 7.5% of children

<60 months of age in India [8]. Several studies had reported a high prevalence of CD in North India particularly, Punjab and Rajasthan, in general population and children [9-12].Considering the high prevalence of CD among the children, it could be a major contributor or comorbid condition in children with SAM. There is very little information currently available regarding the prevalence of CD among children with SAM. The treatment of SAM in the rehabilitation phase involves cereal- based diet, which may have high gluten content. If SAM child has an underlying undetected CD, then the response to cereal based diet will be poor due to gluten content. This study was planned to find out the seroprevalence of CD in children with SAM. The objective of the study was to make the early

screening of CD in SAM children so that gluten-free diet may be started early.

Materials and Methods

The present study was an observational hospital-based prospective study, carried out at Malnutrition Treatment Center (MTC) attached with the ananta institute of medical science & research center Rajsamand, Rajasthan, from February 2019 to January 2020. Written approval from the Institutional Ethical Committee was obtained before the study. After written and informed consent from the parents, total 220 children of either gender who were admitted in MTC and fulfilling the inclusion criteria, were enrolled for the study. Inclusion criteria of this study were all the SAM children(meeting the WHO criteria for SAM) of age 1–5 years admitted in MTC and exposed to gluten containing diet and whom parents willing to enroll their child in the study. Exclusion criteria were: seriously sick SAM, children admitted in pediatric intensive units. Patients with secondary malnutrition – known c/o chronic medical or surgical disorders leading to malnutrition – congenital heart diseases with congestive heart failure, chronic renal failure, hepatic cholestasis, thyrotoxicosis, isolated childhood diabetes mellitus, HIV, childhood tuberculosis, cerebral palsy, genetic/chromosomal syndromes, inborn errors of metabolism, malignancies, surgical resection of intestine, etc., and the patients, who were not exposed to gluten-containing diet. CD seropositivity was accessed by screening for tissue transglutaminase-immunoglobulin IgA (tTg-IgA) and IgG (tTg-IgG) antibodies by enzyme-linked immunosorbent assay method(Aeskulisa tTg-A/tTg-g new generation antigen-based kit). As per manufacturer manual of the kit cutoff value for seropositivity for tTg-IgA/IgG was >18 U/ml (normal range for tTg-IgA and tTg-IgG: 12-18 unit/ml as per manufacturer manual of thekit)(13). All the collected data regarding positivity or negativity of celiac serology were entered and managed in an Excel sheet and analyzed with standard software (SPSS Version 20). P<0.05 was considered significant.

Results:

A total of 220 enrolled cases of SAM, serology for CD (either tTg-IgA or IgG or both IgA and IgG) was positive in 60 (27.28%) cases.A total of 60 seropositive cases, 28 (46.66%) cases were seropositive for both tTg-IgA and IgG, while only tTg-IgA and only tTg-IgG were positive in 18 (30%) and 14 (23.33%) cases, respectively (Table 1).

Table 1: Seropositivity status of cases

Seropositivity Status*	No (%)
Seronegative (Serum tTg-IgA and IgG negative)	160 (72 72)
tTg-IgA Positive	18 (30)
tTg-IgG Positive	14 (23 33)
Both tTg-IgG and IgA positive	28 (46 66)
Total seropositive	60 (100)
Total cases	220 (100)

***Cutoff values: tTg-IgA/tTg-IgG>18 U/ml (as per manufacturer manual of the kit) [13], tTg: Tissue transglutaminase, IgG: Immunoglobulin G, IgA: Immunoglobulin A**

Mean serotiter of serum tTg-IgA and IgG in seropositive cases was 134.01±198.74 (range – 21.04–800) and 49.05±25.74 (range – 22.20–109) unit/ml. Out of 46 tTg-IgA celiac seropositive cases, tTg-IgA titer of <10 times of upper limit of normal (ULN) was present in 34 (73.91%) cases while titer of>10 times of ULN was present in 12 (26.08%) cases (Table 2).

Table 2: CD seropositivity according to tTg-IgA titer (n=23)

tTg-IgA seropositivity	Titer (unit/ml)	No (%)
<10 times of ULN	>18 upto 180	34 (73 91)
>10 times of ULN)	>180	12 (26 08)

***Cutoff value for tTg-IgA: >18 U/ml (as per manufacturer manual for the kit) [13]; ULN-Upper limit of normal, CD: Celiac disease, Tg: Tissue transglutaminase, IgA: Immunoglobulin A**

CD seropositivity was more in males (60%, 36 in 60) as compared to females (40%, 24 in 60), and this difference in seropositivity was statistically insignificant (p>0.05). Celiac seropositivity was maximum (24/60, 40%) in age group of 4–5 years followed by 1–2 years age group (18/60, 30%) (Table 3).

Table 3: Gender and age-wise distribution of seropositivity

Anthropometric measures	Seronegative (n=80) (%)	Seropositive (n=30) (%)
Gender		
Male	94 (58 75)	36 (60)
Female	66 (41 25)	24 (40)
Age		
1–2	98 (61 25)	18 (30)
2–3	30 (18 75)	12 (20)
3–4	10 (6 25)	6 (10)
4–5	22 (13 75)	24 (40)
Total	160 (100)	60 (100)

Discussion:

CD is a common disorder in children with variable presentation wherein, underweight or malnutrition is a common presentation. Clinical manifestation of CD and SAM, in children, overlaps each other. CD may be an underlying cause responsible for malnutrition in these children. Till date, very few studies were conducted to find out the prevalence of CD in children suffering from SAM in the age group of 1–5 years age group [6,7]. We planned and conducted this study to find out and evaluate the seroprevalence of CD in children suffering from SAM. The status of seropositivity in enrolled cases according to the positivity of serology (tTg–IgA/tTg-IgG) was evaluated. Out of total 220 enrolled cases, 60 (27.28%) were seropositive (tTg-IgA/IgG/both IgA and IgG positive) for CD. Out of these 60 seropositive cases, only Ttg -IgA was positive in 18 (8.18%) cases and only Ttg-IgG was positive in 14 (6.63%) cases while both tTg-IgA and IgG were positive in 28 (12.70%) cases. Overall, the seroprevalence of CD was 27.28%. The cases in whom only tTg-IgG were positive (14 cases) may have underlying IgA deficiency, and these case may be missed if accessed for tTg-IgA only.The prevalence reported by Kumar *et al.* [6] was 13.1% (seropositive and biopsy confirmed) among the SAM children. Seroprevalence for CD reported by Beniwal *et al.* [7] was 15.38% while, the prevalence of biopsy-confirmed CD was 14.42% among the SAM children. The

prevalence of CD was more in our study as compared to other reported studies. The reason for this may be that our study is based on celiac serology only as we were not able to perform a duodenal biopsy or HLA typing for confirmation either due non-availability or feasibility at our institute. Other reason may be a high prevalence of SAM in our region having underlying CD presenting as SAM in children. This needs further research.In our study, the mean serotiter of serum tTg-IgA and IgG in seropositive cases was 134.01±198.74 and 43±24.43 unit/ml. We evaluated the CD seropositivity status according to serum tTg-IgA titers. In our study, serum tTg-IgA titer <10 times of ULN was present in 34 (73.91%) cases and serum tTg-IgA titer >10 times of ULN was present in 12 (26.08%) cases. More cases were having tTg-IgA titers of <10 times of ULN due to a low titer of tTg-IgA in these cases. It is well known fact that titer of tTg antibodies depends on the quantity and duration of gluten in the ingested diet.We compared various parameters in CD seronegative and seropositive cases. Seropositivity was more in males as compared to females. Similarly, male preponderance in seropositivity was reported by Kumar *et al.* [6] and Sharma *et al.* [14]. This suggests gender biases in society as more male children are brought for admission as compared to females. CD seropositivity was maximum in the 4–5 years age groups, suggesting the cumulative effect of gluten in the ingested diet with age. In our study, we observed high seroprevalence of CD in children suffering from SAM.The study has a few limitations, for example, only hospitalized SAM patients were included in this study. Children suffering with SAM at the community level also should be included for true seroprevalence of CD in SAM. We were not able to estimate serum IgA level to rule out serum IgA deficiency and presumed all tTg-IgA negative but tTg-IgG positive cases as IgA deficient. Our study was purely based on celiac serology for the prevalence of CD. We were not able to do upper gastrointestinal endoscopy for duodenal biopsy or HLA typing due to non-availability/feasibility at our center or expanse involved in these investigations.

Conclusions

We found high seroprevalence of CD in children of 1–5 years age, suffering from SAM which is much higher than the prevalence reported in the general population. We should have a high index of suspicion in children suffering from SAM. It is recommended that early screening and diagnosis of CD in these children by celiac serology should be done where the facility of duodenal biopsy/HLA typing not available/possible followed by gluten-free diet challenge in celiac seropositive cases.

Abstract

Introduction: Neonatal sepsis can be defined as a clinical condition which is characterized by signs and symptoms of infection in an infant 28 days of life or younger. This is manifested by systemic signs of infection and/ or isolation of a bacterial or other pathogen from the bloodstream. Sepsis is still one of the major causes of morbidity and mortality globally in neonates, despite of recent advances in healthcare units. The incidence of neonatal sepsis by bacteremia in asymptomatic infants is low. In neonatal sepsis we can include septicemia, pneumonia, meningitis, osteomyelitis, and arthritis and urinary tract infections. The burden for neonatal sepsis was 2,202 (95% CI: 1,099–4,360) per 100,000 live births, with mortality between 11% and 19% and more than 40% of under-five deaths occur in the neonatal period, resulting in 3.1 million new-born deaths each year globally.**Material and methods:** The total number neonates admitted in the hospital in given study period was 447, of which 198 were diagnosed for neonatal sepsis by the physician based on the signs and symptoms during admission. The data was collected in three parts: sociodemographic characteristics: maternal information; and part neonatal information for neonatal sepsis. Data was collected in the excel sheet and questionnaires were reviewed and organized by investigators.**Results:** Of the 198 neonates, 162 (81.8%) infants were in the age range of 0 to 7 days while 36 (18.2%) were aged between 8 and 28 days. Statistically significant difference was observed between early onset and late onset sepsis patients. Out of 198 cases 107 (54%) were male while 91(46%) were female. In early onset sepsis cases maternal UTI, Meconium stained amniotic fluid, Multipara and Premature rupture of membrane was seen in 24(14.8%), 21(13.0%), 19(11.7%) and 32 (19.8%) cases respectively. In late onset sepsis cases maternal UTI, Meconium stained amniotic fluid, Multipara and Premature rupture of membrane was seen in 1(2.8%), 2 (5.6%), 4(11.1%) and 2 (5.6%) cases respectively. Maternal risk factors were identified in 104(64.2%) of early onset sepsis cases while maternal risk factors in late onset sepsis cases were 10(27.8%). Culture positivity was observed in 28 (17.3%) cases of early neonatal sepsis while it was 4 (11.1%) in late onset sepsis.**Conclusion:** There was male preponderance in early as well as late onset neonatal sepsis. Maternal risk identification may help in the early identification and timely empirical antibiotic therapy. The prediction and/ or diagnosis of neonatal sepsis should be bases on culture-independent diagnostics and risk factor-based scoring systems.

Keywords: Neonatal,sepsis,antibiotic,therapy

Introduction

Among term and preterm infants neonatal sepsis is one of the leading causes of morbidity and mortality[1]. Also it contributes significantly to mortality and morbidity among very-low-birth-weight (VLBW, weight less than1500 gm) infants in Neonatal Intensive Care Units (NICU)[2]. Mortality in the neonatal period each year account for 41% (3.6 million) of all deaths in children under 5 years and most of these deaths occur in low income countries and about one million of these deaths are attributable to infectious causes including neonatal sepsis, meningitis, and pneumonia [3]. Neonatal sepsis can be defined as a clinical condition which is characterized by signs and symptoms of infection in an infant 28 days of life or younger. This is manifested by systemic signs of infection and/ or isolation of a bacterial or other pathogen from the bloodstream[4].Sepsis is still one of the major causes of morbidity and mortality globally in neonates, despite of recent advances in healthcare units. The burden for neonatal sepsis was 2,202 (95% CI: 1,099–4,360) per 100,000 live births, with mortality between 11% and 19% and more than 40% of under-five deaths occur in the neonatal

period, resulting in 3.1 million new-born deaths each year globally[5,6]. In neonatal sepsis we can include septicemia, pneumonia, meningitis, osteomyelitis, arthritis and urinary tract infections[7]. Clinical features are generally non-specific and are inefficient for identifying neonates with early-onset sepsis (EOS)[8]. The incidence of neonatal sepsis by bacteremia in asymptomatic infants is low[9]. Full term infants are more likely to react to a bacterial infection with fever while preterm newborns were more likely to react with hypothermia, because of transitional difficulty with temperature control especially in the first two days[10,11]. Respiratory distress with tachypnea, nasal flaring, grunting and retraction of respiratory muscles can be the manifestation of sepsis with or without pneumonia and this can be confused with transient tachypnea of newborn initially. Neonatal sepsis can be complicated by metastatic foci of infection, disseminated intravascular coagulation, congestive heart failure and shock[12]. Based on the timing of the infection neonatal sepsis has been classified into early-onset sepsis (EOS) and late-onset sepsis (LOS)[13]

Material and methods

The present study was conducted at Ananta Institute of Medical Sciences and Research Centre Rajsamand, Rajasthan. This study was carried out using institution based cross section study in the department of pediatrics. The total number neonates admitted in the hospital in given study period was 447, of which 198 were diagnosed for neonatal sepsis by the physician based on the signs and symptoms during admission. The data was collected in three parts: sociodemographic characteristics; maternal information; and part neonatal information for neonatal sepsis. Data was collected in the excel sheet and questionnaires were reviewed and organized by investigators. The data were entered after defining variables and analyzed using SPSS v. 20.0 statistical software. Statistical significance was shown if p value less than 0.05 for multivariable and 0.25 for bivariate logistic regressions. Finally, the result is presented using tables and texts.

Results

Among 447 neonates admitted 198 (44.3%) were diagnosed for neonatal sepsis by the physician based on the signs and symptoms during admission. Of the 198 neonates, 162 (81.8%) infants were in the age range of 0 to 7 days while 36 (18.2%) were aged between 8 and 28 days. Statistically significant difference was observed between early onset and late onset sepsis patients.

Table 1: Onset of neonatal sepsis

Age	Number [% (n=198)]	P value
0 to 7 days	162(81.8%)	P < 0.0001
8 to 28 days	36(18.2%)	
Total	198	

Table 2: Male to female ratio

Gender	Early onset sepsis	late onset sepsis	Total
Male	86(80.4%)	21(19.6%)	107
Female	76(83.6%)	15(16.4%)	91
Total	162(81.8%)	36(18.2%)	198

Out of 198 cases 107 (54%) were male while 91(46%) were female. Of the 107 males 86(80.4%) were of early onset sepsis while 21(19.6%) were late onset sepsis. Of the 91 females 76(83.6%) were early onset sepsis while 15(16.4%) were diagnosed as late onset sepsis.

Table 3: Maternal risk factors

Risk factors	Early onset sepsis (n= 162)	%	Late onset sepsis (n=36)	%
Foul smelling liquor	8	4.9%	1	2.8%
Maternal UTI	24	14.8%	1	2.8%
Meconium stained amniotic fluid	21	13.0%	2	5.6%
Multipara	19	11.7%	4	11.1%
Premature rupture of membrane	32	19.8%	2	5.6%
Total	104	64.2%	10	27.8%

UTI: Urinary tract infection

Maternal risk factors were identified in 104(64.2%) of early onset sepsis cases while maternal risk factors in late onset sepsis cases were 10(27.8%). Maternal risk factor foul smelling liquor in early onset sepsis and in late onset sepsis was 8 (4.9%) and 1 (2.8%) respectively. In early onset sepsis cases maternal UTI, Meconium stained amniotic fluid, Multipara and Premature

rupture of membrane was seen in 24(14.8%), 21(13.0%), 19(11.7%) and 32 (19.8%) cases respectively. In late onset sepsis cases maternal UTI, Meconium stained amniotic fluid, Multipara and Premature rupture of membrane was seen in 1(2.8%), 2(5.6%), 4(11.1%) and 2 (5.6%) cases respectively.

Table 4: Culture positive cases

Type	Culture positive	Percentage
Early onset sepsis	28	17.3%
Late onset sepsis	4	11.1%

Culture positivity was seen in 28 (17.3%) cases of early neonatal sepsis while it was 4 (11.1%) in late onset sepsis.

Discussion

Globally, there are three million annual neonatal sepsis cases (2202/ 1,00,000 live births) while India has the highest incidence of clinical sepsis (17,000/ 1,00,000 live births). The case fatality rate of sepsis among neonates is between 25% to 65% in India[15]. The application of a risk-factor based approach for guidance of the management decisions has been debated with relation to its cost-effectiveness. It has, however, been shown to be one of the highly effective approaches for reducing neonatal early-onset sepsis (EOS)-based mortality in High Income Countries. So it is adviced in resource-limited settings with a high neonatal mortality rate, such as in India, a combination of risk factors and clinical signs should guide the intrapartum and neonatal management[16]..In our study maternal risk factors were identified in 104(64.2%) of early onset sepsis cases while maternal risk factors in late onset sepsis cases were 10(27.8%). In studies it was evident that the maternal risk factors are important in early onset sepsis particularly of Group B Streptococcal aetiology[17]. Such evidence can help to design risk-factor based eligibility criteria for intervention studies on neonatal sepsis [18]. Also it has been suggested that maternal factors such as premature delivery and premature rupture of membrane have also been implicated as significant risk factors in a meta-analysis on neonatal early onset sepsis[14].In our study 107 (54%) were male while 91(46%) were female. Of the 107 males 86(80.4%) were of early onset sepsis while 21(19.6%) were late onset sepsis. Of the 91 females 76(83.6%) were early onset sepsis while 15(16.4%) were diagnosed as late onset sepsis. Higher incidences of sepsis in male were shown in other studies possibly based on the male disadvantage hypothesis[19,20]. It was found that 28 (17.3%) cases of early neonatal sepsis while it was 4 (11.1%) in late onset sepsis were culture positive. In other studies culture positive cases ranges from 25% to 45%[20]. But the disadvantage of culture is it takes around 48 hours to give the positive report and has risk of false-positive or low-yield results after antenatal antibiotic exposure[21].

Conclusion

There was male preponderance in early as well as late onset neonatal sepsis. Maternal risk identification may help in the early identification and timely empirical antibiotic therapy so that mortality and morbidity can be reduced. The prediction and/ or diagnosis of neonatal sepsis should be bases on culture- independent diagnostics and risk factor-based scoring systems.

ABSTRACT:

Background: Pneumonia is the leading cause of morbidity and mortality in under 5 year age children. Objective: To compare the effectiveness of treatment for Community Acquired Pneumonia (CAP) in children with narrow versus broad spectrum antibiotic therapy. Methods: A prospective randomized controlled trial was conducted in Pediatric ward of tertiary care medical college hospital of southern Rajasthan from July 2017 to June 2018. Total 184 children of age group of 2 months to 18 years, admitted with a clinical diagnosis of CAP were enrolled for the study. Results:A total 184 children were enrolled.Maximum no. of cases (93) admitted with CAP were among 2 months to 12 months of age group. All 6 parameters in our study (i.e. total duration of fever, O_2requirement, respiratory distress, length of stay, change of antibiotic and readmission) were compared between both the groups suggesting that Ampicillin having similar effect on children hospitalized with CAP when compared with Ceftriaxone.Throat swab culture in children with CAP was positive in 55% of cases. Most common organism grown on throat swab of affected children was Streptococcus pneumoniae (30%) followed by H.influenzae (15%).Conclusion:CAP is a major health problem in children below 5 years. Most common organism for CAP in children is still S.pneumoniae. In our study narrow spectrum antibiotic coverage for CAP was associated with similar outcomes when compared with broad spectrum agent. So we highlights in our study to promote the use of narrow spectrum antibiotics in children hospitalized with CAP.

Keywords: Community Acquired Pneumonia, Ampicillin, Ceftriaxone, S.pneumoniae.

Introduction

Pneumonia is defined as "An acute inflammation of the pulmonary parenchyma that can be caused by various infective and noninfective origin".[1]On the basis of source of infection it has been classified ascommunity acquired, health care associated, ventilator associated and hospital acquired pneumonia.Pneumonia affects 156 million children under age of 5 years every year across the globe, and is the leading cause of morbidity and mortality in this age group.[2] More than 2 million annual deaths are estimated to occur because of pneumonia in under 5 children and almost all of them are occurring in developing world.[3]India carries the largest burden of the disease and death because of pneumonia, approximately for 43 million cases and 0.4 million deaths annually.[4]Childhood pneumonia is an important cause of morbidity and mortality worldwide. More than 2 million children younger than five years of age die from pneumonia every year, accounting for almost one-fifth of overall childhood mortality. [5]The respiratory rate thresholds for acute lower respiratory tract infection according to the WHO are a respiratory rate of > 60/minute for children less than 2 months of age, > 50/minute for children aged 2 to 12 months, and >40 /minute for children aged 1 to 5 years (WHO,1990). This easily detected diagnostic sign of pneumonia is helpful in the developing world where radiographic facilities are rarely available, trained staff are lacking, and pneumonia mortality is high.The short distance between upper respiratory tract and alveoli, the small diameter of the airways, profuse mucus production, and the immaturity of the immune defence predisposes children to pneumonia. In addition, the nasopharyngeal colonization of pneumonia causing bacteria is common in young children.[6,7,8]Although most cases of pneumonia are caused by microorganisms, noninfectious causes include aspiration (of food or gastric acid, foreign body, hydrocarbons), hypersensitivity reactions or drug induced pneumonitis.[9]

Community-acquired pneumonia (CAP) is an acute lower respiratory tract infection (LRTI) acquired from the community with fever, cough, dyspnea, tachypnea and pleural chest pain as typical symptoms. Diagnosis is confirmed with new opacity in chest radiograph.[10,11,12]. Appropriate antibiotic prescribing is associated with favorable level of antimicrobial resistance and clinical outcome. In October 2011, Pediatrics Infectious Disease Society (PIDS) and Infectious Disease Society of America (IDSA) published guidelines for the management of CAP in children.[13]In prospective, microbiology-based studies, the leading bacterial cause is S. Pneumoniae, being identified in 30–50% of pneumonia cases.[14] The second most common organism isolated in most studies is **H. influenzae** type b (Hib; 10–30% of cases), followed by S. aureus and K. pneumoniae.Some of Indian studies had also reported as S. Pneumoniae and H.Influenzae being the most common causes of CAP in children of age group 2months to 5 years of age.[15,16]. Narrow spectrum beta lactams effectively target S. Pneumoniae. New guidelines recommend Penicillin or Ampicillin/Amoxicillin as first line therapy for the most children hospitalized with CAP.[13]

Material and method

A prospective randomized controlled study was carried out in Pediatric ward of tertiary care hospital of southern Rajasthan attached with medical college.

Study period: Jan.2019 to Dec. 2019

Study population: Total 184 children of age group of 2 months to 18 years were admitted with a clinical diagnosis of CAP were enrolled for the study.

INCLUSION CRITERIA:

ISSN 2515-8260 Volume 7, Issue 8, 2020

1. Children only whose parents have given consent to participate in the study will be included in this study.
2. Children of age group 2 months to 18 years of age hospitalized with diagnosis of CAP.
3. Evidence of respiratory illness (cough/increased work of breathing).
4. Chest radiograph showing Pneumonia (e.g. Infiltrates or consolidation)
5. Patients who received a minimum of 2 days antibiotic therapy during hospitalization

EXCLUSION CRITERIA:

1. Children whose parents refused for participation in the study.
2. Children with severe pneumonia who required ICU admission within 48 hours of hospitalization.
3. Children with some congenital/chronic respiratory illness. (e.g. Cystic fibrosis, asthma ,lung malformation)
4. Complicated pneumonia (defined as imaging study indicating moderate to large pleural effusion, lung abscess , necrosis or bronchopulmonary fistula)
5. Children who got hospitalized within last 30 days due to any illness
6. Children who received staphylococcal coverage / macrolide monotherapy within last 7 day

Prior written informed consentwas obtained from the parents or available relatives of each child. Confidentiality of data was ensured.Cases were enrolled within 6 hours of admission.All the enrolled children included in the study were divided into 2 groups: Patient with odd no. of sequences named as group A and patient with even no. as group B.Basic information of the child, detailed clinical history and treatment history was obtained followed by general physical and systemic examination done. All the informations were recorded on structured proforma.Routine investigations includingHemoglobin, TLC, DLC and Chest x-ray were done in all the patients at time of admission. Sample for blood culture was collected in every patient before starting antibiotic. Similarly throat swab sample was also taken for culture of organism.

Pneumonia was diagnosed as per WHO ARI control program. Respiratory rate was counted for one full minute when the child was calm, sleeping or feeding. Fast breathing was defined as respiratory rate above the limit as defined by WHO[17]. The presence of subcostal indrawing, suprasternal indrawing and intercostal indrawing was assessed. Positive findings were noted on basis of symptoms and clinical examination.

Microbiology: Processing of 368 samples (184 blood culture + 184 throat swab culture)was done in Microbiology Department of the institute. All the samples were collected with aseptic precautions by using standard sterile techniques and transported to the laboratory as soon as possible maintaining optimum transportation conditions.

The following procedures were carried out in the laboratory –

1. Gram's staining
2. Bacteriological culture
3. Biochemical reactions
4. Antibiotic sensitivity testing

ISSN 2515-8260 Volume 7, Issue 8, 2020

Direct gram stained smear of the samples observed under microscope to detect the presence and type of bacteria and to correlate it with the growth obtained on culture plate.Primary inoculation was done on the Thio-glycolate broth, Mac Conkey media and Blood agar. Colony characteristics were observed.

Antimicrobial susceptibility testing: The isolates tested by the disc diffusion method (modified Kirby-Bauer method) on Muller Hinton agar (Hi-Media) following the zone size criteria which is recommended by the CLSI .

After initial workup selection of antibiotic was decided according group. Group A patients received narrow spectrum antibiotic therapy in form of injection Ampicillin intravenously at dose of 50mg/kg/dose every 6 hourly while group B received broad spectrum antibiotic therapy in form of injection Ceftriaxone intravenously at dose of 50mg/kg/day divided in two doses. Patients were discharged once the symptoms relieved and need of intravenous therapy was not there with further advice to complete 7 to 10 days of therapy with oral antibiotic therapy.

Effect of narrow versus broad spectrum antibiotic therapy compared in both the groups based upon following parameters in each group:

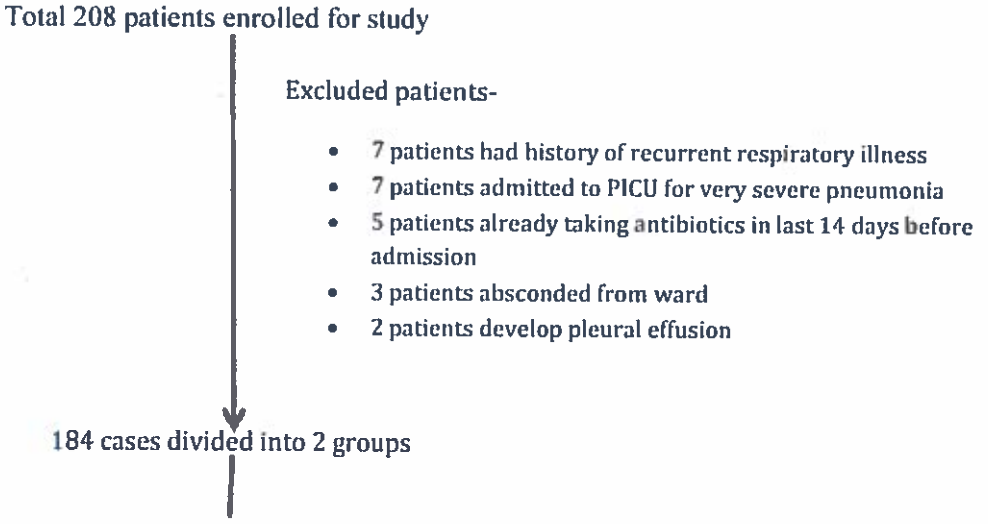
1. Duration of fever (Temp. >38 ^{0}c).
2. Duration of supplemental oxygen required (hours).
3. Hospital length of stay (LOS) measured in hours.
4. Signs of respiratory distress.
5. Readmission within 15 days of discharge from hospital.
6. Required changing of antibiotics.

STATISTICAL ANALYSIS :

Data analysis was done by SPSS software (20.0 trial version) and appropriate statistical tests were used to find out the final results.

Results

Total 208 children of age group 2months to 18 years were admitted with diagnosis of CAP in children ward of the hospital, out of them 24 children were excluded and final 184 children categorized into two groups (92 each).



ISSN 2515-8260 Volume 7, Issue 8, 2020

Maximum no. of cases admitted with CAP were among 2 months to 12 months of age group(93) followed by 1- 2year (26) and 2-3(28) year of life. Patients older than 5 year were only 9.8% (18)of total patients with CAP(Table 1). All patients admitted for CAP were having tachypnoea and chest indrawing *(100%)* at admission. But fever *(94.6%)* and cough *(92.4%)* was not consistent finding in all children.

Outcome measures for both groups were compared in form of total duration of fever, O_2 requirement and signs of respiratory distress (in form of tachypnoea, grunting, chest retractions). All outcomes were measured in duration of hours from the time of hospitalization.Table 2 depicts thattotal duration of fever in Ampicillin group was 18.4 hours which was almost similar to Ceftriaxone group (18.9 hours). Difference among these was statistically not significant (p 0.636).Similarly duration of O_2 required in both groups was also similar (Ampicillin: 14.6 vs. Ceftriaxone: 17.7 hours). p value 0.58 suggests that this difference was also not significant.Signs of respiratory distress in Ampicillin group were lasted for a mean of 36.0 hours which was quite similar to Ceftriaxone group (mean 37.9 hrs). p value 0.392 is suggesting of this difference not significant.

Out of 92 patients received Ampicillin, 8 patients (8.7%) required change of antibiotic during their hospitalization, while Ceftriaxone group required change of antibiotic in 5(5.4%) patients(Table 3). (p=0.388) suggesting of difference between both groups in this parameter to be not significant.We compared the total length of stay in hospital for I.V. antibiotics in both group (Table 4). Patients in Ampicillin group had lesser stay in hospital as compared to Ceftriaxone group (77.2 vs 80.6 hrs, p =0.149). The difference was not significant so both drugs were similar in this outcome also.Out of 92 patients in each group only 2 patients in each group required readmission with 15 days after discharge from hospital(Table 5). So all 6 parameters in our study (i.e. total duration of fever, O_2, respiratory distress, LOS, change of antibiotic and readmission) were compared between both groups and they were statistically not significant suggesting that Ampicillin having similar effect on children hospitalized with CAP when compared with Ceftriaxone.

In our study we sent blood and throat swab samples for culture and sensitivity of organism in every patient. Out of 184 patients only 13 (7%) patients have shown growth of some organism in their blood sample obtained from venipuncture (Table 6).Throat swab culture in children with CAP were positive in more number of cases 96 (55%) as compared to blood culture of same patients (positive in 7%). It is suggestive of that throat swab culture is a better mode for detection of causative organism responsible for pneumonia in children. Table 6 depicts thatmost common organism grown on throat swab of affected children was Streptococcus pneumonia (30%) followed by H.influenzae (15%). These two are the most common organism responsible for CAP in children between age group 2 months to 5 years of age.We found that out of those 96throat swab culture positive cases 17 were resistant to Ampicillin (9.2%) and 15 Patients (8.2%) were resistant to Ceftriaxone. It suggest that sensitivity pattern for organisms causing CAP in local population is similar in both narrow (Ampicillin) and broad (Ceftriaxone) spectrum groups (Table 7). Most common organisms for CAP in children (S.pneumoniae, H.influenzae) are having similar sensitivity and resistance pattern for

ISSN 2515-8260 Volume 7, Issue 8, 2020

both group of antibiotics.52% of S. pneumoniae positive case were from age group 2-12months while only 1 case was >5 year age. Similarly H.influenzae was also common in infantile age (39%).

Discussion: According to our study majority of children admitted with CAP were among infantile age group. 50% of cases were of age group 2months to 12 months and only 9.8% of cases were older than 5 year of age.Williams BG et al[5]Bryce J et al[2]and Wardlaw T et al[18] observed in their studies that childhood pneumonia is an important cause of morbidity and mortality worldwide.

In our study all children were having respiratory distress in form of tachypnoea at time of admission as we used WHO criteria for defining Pneumonia.Palafox and colleagues found that the presence of tachypnea was the single most sensitive and specific clinical indicator of pneumonia, with 74 % sensitivity and 67 %specificity among children less than 5 years of age.[19]Duration of fever in Ampicillin group (18.4 hrs) was similar to Ceftriaxone group (18.9hrs) (p value 0.636).Williams DJ et al [20] in their retrospective cohort study observed that duration of fever in patients receiving narrow spectrum antibiotic was similar to braod spectrum group when they studied among 43 children hospitals.

Total duration O_2 supplementation required was less in narrow spectrum group (Ampicillin 14.6 hrs vs Ceftriaxone 17.7 hrs), but this difference is statistically not significant (p value 0.058).Marry N Queen [4] also observed that children receiving narrow spectrum antibiotics were having less duration of oxygenation (mean 15.6 hrs) as compare to children who received broad spectrum antibiotics (mean 21.8 hrs). This difference was also not significant (p value 0.18). Out of 92 patients received Ampicillin, 8 patients (8.7%) required change of antibiotic during their hospitalization, while Ceftriaxone group required change of antibiotic in 5(5.4%) patients. (p=0.388) suggesting of difference between both groups in this parameter to be not significant.We compared the total length of stay in hospital for I.V. antibiotics in both group (Table 4). Patients in Ampicillin group had lesser stay in hospital as compared to Ceftriaxone group (77.2 vs 80.6 hrs, p =0.149).Williams DJ et al [20] compared the LOS in both groups in terms of total days and they found it similar (3-4 days for both narrow & broad spectrum groups) while Marry N Queen [4] mentioned it in total hours. Though it was shorter in narrow spectrum groups (43 hrs vs 52.3 hrs, p=0.04). Out of 92 patients in only 2 patients in each group required readmission with 15 days after discharge from hospital. Williams DJ et al [20] compared the readmission within 14 days while Marry N Queen [4] compared readmission within 7 days of discharge from hospital. In both studies difference between both groups was not significant.

So all 6 parameters in our study (i.e. total duration of fever, O_2, respiratory distress, LOS, change of antibiotic and readmission) were compared between both groups and they were statistically not significant suggesting that Ampicillin having similar effect on children hospitalized with CAP when compared with Ceftriaxone.In our studythroat swab culture in children with CAP were positive in more number of cases (55%) as compared to blood culture of same patients (7%). It is suggestive of that throat swab culture is a better mode for detection of causative organism responsible for pneumonia in children.Das et al [21] also demonstrated the same difference while comparing results of blood culture and OPS and BAL samples from children with CAP. Only 4 samples were positive in blood culture out of 180, while 131 children showed growth of organism in their OPS and BAL samples. The difference was significant.

Most common organism grown on throat swab of affected children was Streptococcus pneumoniae (30%) followed by H.influenzae (15%). These two are the most common organism responsible for CAP in children between age group 2 months to 5 years of age.Various other studies like Nantanda R et al [22] Hortal M et al [23] and Gratten M et al [24] have found S.pneumoniae & H.influenzae to be the most common isolate from respiratory samples of children with CAP. S.aureus and K.pneumoniae

ISSN 2515-8260 Volume 7, Issue 8, 2020

were detected as leading cause of pneumonia by Johnson et al[25]. Das et al [21] also found S.pneumoniae and H.influemzae as the leading cause of CAP in children under 5 year.There were total 96 patients in whom throat swab culture was positive. We found that out of those 96 cases 17 were resistant to Ampicillin (9.2%) and 15 Patients (8.2%) were resistant to Ceftriaxone. It suggest that sensitivity pattern for most common organisms causing CAP in local population is similar in both narrow (Ampicillin) and broad (Ceftriaxone) spectrum groups of antibiotics.

Conclusion: We can summarize results of our study as CAP is a major health problem in childrenbelow 12 months. In the modern era of antibiotic resistance we should avoid overuse of broad spectrum antibiotics. Most common organism for CAP in children is still S.pneuminae and its sensitivity to narrow spectrum antibiotics like Ampicillin is good in local population also. So misconception about PIDS and IDSA guideline that this has to be followed in developed countries is not true. Narrow spectrum antibiotic coverage for CAP associated with similar outcomes when compared with broad spectrum agents. There was no difference in total duration of fever, O_2 requirement, respiratory distress, length of stay in hospital, change of antibiotic and readmission rates. So we highlights in our study to promote the use of narrow spectrum antibiotics in children hospitalized with CAP.There exist many reasons to preferentially use penicillins as first line antibiotic therapy for CAP. First penicillins provide appropriate coverage for the most prominent pathogen, S.pneumoniae. Second treatment of patients with non-central nervous system penicillin-resistant pneumococcal infections with penicillins has not been associated with treatment failures. Finally the use of broad spectrum antibiotics has been shown to increase the risk of developing subsequent infections with resistant organisms.

Abstract

Pediatric Intensive Care Unit (PICU) plays a very important role in the care of critically-ill children who are at risk for organ dysfunction. Worldwide the most common causes of morbidity and mortality in children is sepsis particularly in developing countries. Especially in children there is high rate of mortality in septic shock may be as high as 50%. In septic shock, outcome is worse when associated with co-morbidities. The clinical syndrome of shock, a clinical state characterized by inadequate tissue perfusion, is one of the most dramatic, dynamic and life-threatening problems faced by the physician in the critical care setting. Shock is defined as an acute syndrome in which the circulatory system is not able to supply adequate amount of nutrients and oxygen for vital organs. In children Shock accounts for more morbidity and mortality worldwide than any other disease, especially when shock is accompanied by need of mechanical ventilation.**Aim:** The main objective of this study is to know clinical profile and outcome of shock in children. Material and method: Children with the different age group between 1 to 15 years old age admitted with the clinical evidence of shock in the pediatric emergency. From all the patients' detailed clinical history were taken with the help of their relatives or parents. For the identification of shock in the patients, there must be present of at least one of the following parameters i.e., tachycardia and/or hypotension along with signs of systemic hypoperfusion. From all the patients laboratory investigation were done like blood culture, C-reactive protein, liver function tests, urine routine and culture, stool routine and culture, calcium, urine electrolytes, etc. were done.Result: Out of total patients 20, 17 and 13 were in age group 1-5 years, 5-10 years and 10-15 years respectively. In this study maximum male gender were predominate to female with the ratio 1.5:1 and the mean age were 5.8 ± 3.4 years. Congenital heart disease (54.2%) was the most common underlying etiology in cardiogenic shock followed by cardiomyopathy (24.5%) and heart rate abnormalities (21.3%). In hypovolemic shock, 87.9% patients were in compensated stage of septic shock.**Conclusion**: Especially in children Shock is a major cause of morbidity and mortality. Hypovolemic shock is the commonest form of shock in children which required mechanical ventilation. In septic shock severe pneumonia was the commonest illness. Hence, Diagnosis and management of shock in reimburse stage bring better forecast than in uncompensated shock irrespective of the age.

Keywords: PICU, Hypovolemia, Cardiogenic, Shock, Outcome

Introduction

Pediatric Intensive Care Unit (PICU) plays a very important role in the care of critically-ill children who are at risk for organ dysfunction[1]. Worldwide the most common causes of morbidity and mortality in children is sepsis particularly in developing countries [2]. According to World Health Organization (WHO), worldwide there are mainly four causes of death in children are severe Pneumonia (1.9 million deaths/ year), severe diarrhea (1.6 million/year), severe malaria (1.1 million/year), severe measles (5,50,000 deaths/ year). Therefore WHO used term severe when children develop acidosis or hypotension or both[3]. Especially in children there is high rate of mortality in septic shock may be as high as 50%.In septic shock, outcome is worse when associated with co-morbidities[4]. The clinical syndrome of shock, a clinical state characterized by inadequate tissue perfusion, is one of the most dramatic, dynamic and life-threatening problems faced by the physician in the critical care setting[5]. Shock is defined as an acute syndrome in which the circulatory system is not able to supply adequate amount of nutrients and oxygen for vital organs[6]. Because of inadequate production of ATP for the support and function of the cell then it revert to anaerobic metabolism, causing acute energy failure[7]which results in the cell being unable to maintain homeostasis, accumulation

of intracellular sodium, accumulation of cytosolic calcium, disruption of ionic pumps, efflux of potassium and eventual cell death. More no of cell death results in multi-organ dysfunction. In children Shock accounts for more morbidity and mortality worldwide than any other disease, especially when shock is accompanied by need of mechanical ventilation[8,9]. The main objective of this study is to know clinical profile and outcome of shock in children.

Material and method

This is a prospective study carried out in pediatric intensive care unit (PICU) at Ananta institute of medical science & research centre Rajsamand, Rajasthan. Total 50 pediatric patients were included in this study during the period of 1 year. Children with the different age group between 1 to 15 years old age admitted with the clinical evidence of shock in the pediatric emergency.From all the patients' detailed clinical history were taken with the help of their relatives or parents. For the identification of shock in the patients, there must be present of at least one of the following parameters i.e.,tachycardia and/or hypo-tension along with signs of systemic hypo-perfusion[10]. According to the presence of hypo-tension Patients were classified into compensated or decompensated shock. With the presence of hypotension and cold extremities Cold septic shock was identified. On the basis of history and physical examination Shock was then classified functionally into hypovolemic, cardiogenic, septic and distributive [11,12]. From all the patients laboratory investigation were done like blood culture, C-reactive protein, liver function tests, urine routine and culture, stool routine and culture, calcium, urine electrolytes, etc. were done.

Result

In this study total 50 patients with shock admission in the hospital were included in the study period. Out of total patients 20, 17 and 13 were in age group 1-5 years, 5-10 years and 10- 15 years respectively. In this study maximum male gender were predominate to female with the ratio 1.5:1 and the mean age were 5.8 ± 3.4 years. Various types of shock with age wise distribution were shown in table no 1 below.

Table 1: Showing Age Wise Distribution with various types of Shock

Age(yrs)	1-5	5-10	10-15	Total
Total cases of shock	20	17	13	50
Hypovolemic shock	9	7	7	23
Septic shock	6	5	3	14
Cardiogenic shock	5	4	2	11
Distributive shock	0	1	1	2

Nearly 64% of cases were in compensated stage of shock, which was not significantly related to age. Dehydration following diarrhea and vomiting was most common underlying etiology in hypovolemic shock. Congenital heart disease (54.2%) was the most common underlying etiology in cardiogenic shock followed by cardiomyopathy (24.5%) and heart rate abnormalities (21.3%). In hypovolemic shock, 87.9% patients were in compensated stage of septic shock. As per the stage of shock and outcome is shown in table no: 2 below.

Table 2: Showing the various Stage and Outcome of types of Shock

Types of shock	Compensated stage	Decompensated	Survival (%)*
Hypovolemic	18	5	22(95.7)
Septic	5	9	6(42.9)
Cardiogenic	7	4	4(36.4)
Distributive	2	0	2(100)
Total	32	18	34(68)

*Survival is calculated after excluding patients who left against medical advice

Discussion

In worldwide shock is a major cause of morbidity and mortality in critically ill children. 4.6% is The frequency of shock noted in pediatric intensive care. Hypovolemic shock was the most commonly encountered shock followed by Septic shock. Many researches in developed countries showed that about 2% shock occurs in all hospitalized infants, children and adults. Depending on the etiology and clinical scenario mortality varies[13] in developing countries There is sparse data about the incidence of shock. Many studies in India have reported frequency of 4.3%, and 9% in another studied which corresponds to this study[14,15]. In this study children under 5years of age were majorities which are consistent with the previous studies[16]..Due to diarrhea and vomiting Hypovolemic shock was the most common type of shock in this study which is similar to the different studied of Perkin RM et al[17], Singhi S et al[18] and Chang P et al[19]. Cardiogenic shock during childhood represents a diagnostic and therapeutic challenge because of its multitude etiologies[20]. In cardiogenic shock cardiomyopathies,

congenital heart diseases and Heart rate abnormalities are the common causes. This is traditionalism to the fact that in compensated stage, vital organ perfusion is maintained by intrinsic mechanism with early detection and management of shock that increases rate of survival before hypotension develop[21,22]. High mortality was observed in septic shock in this study which is similar to the other studied of Pollack MM et al[23]. though the mortality rates have declined over the past several decades to less than 20% as studied showed by Kutko MC et al[24]. Management of shock in children requiring mechanical ventilation requires good infrastructure, trained staff and protocol-based management.

Conclusion

Especially in children Shock is a major cause of morbidity and mortality. Hypovolemic shock is the commonest form of shock in children which required mechanical ventilation. In septic shock severe pneumonia was the commonest illness. Therefore larger prospective study in developing countries is advisable. Hence, Diagnosis and management of shock in reimburse stage bring better forecast than in uncompensated shock irrespective of the age.

ABSTRACT

Introduction-Thyroid hormone abnormalities are commonest endocrine disorders in India and also the commonest preventable cause of mental retardation. Objectives-To determine the prevalence, clinical profile and etiology of thyroid dysfunction in children. Materials and Methods- A hospital based prospective observational study performed in newborns and children below 18 years fulfilling the inclusion criteria visiting the pediatric OPD and IPD in Ananta Institute of Medical Science & Research Centre Rajsamand, Rajasthan. If they had clinical suspicion of thyroid dysfunction. Patients having normal TSH levels defined by age wise cut offs were not evaluated further. Thyroid profile consisting of Free T4 , Total T4,TSH levels were done if there was suspicion of hypothyroidism and Free T3 and TSH if there was suspicion of hyperthyroidism. Other investigations like USG thyroid, thyroid 99^{m} technetium scan anti TPO and anti TG antibody levels were done to look for the etiological diagnosis. Appropriate treatment was started according to standard guidelines. Results- Out of 252, 35 children were found to have thyroid dysfunction, 34 were having hypothyroidism and 01 was having hyperthyroidism. Overall male to female ratio in our study was 1:4. Most common clinical presentation in hypothyroidism cases were constipation followed by short stature. Autoimmune hypothyroidism was the most common etiology. Prevalence of goiter in the study was 20%. 07 cases were congenital hypothyroidism. Treatment was started according to standard guidelines. Conclusion- Autoimmune thyroid diseases are now the major leading cause of thyroid disorders in childhood. There is high prevalence of thyroid dysfunction in children in and around the rajsamand.

Key words- Autoimmune thyroid diseases ,thyroid dysfunction , thyroid stimulating hormone.

ISSN 2515-8260 Volume 7, Issue 8, 2020

INTRODUCTION

Disorders of thyroid gland are commonest endocrine disorder in India.[1]In pediatric age group thyroid hormones are primarily concerned with maintenance of growth, metabolism and mental development[2,3] .Thyroid hormones deficiency in infancy leads to irreversible impairment of neuro-cognitive function and physical and mental retardation [3].It is a spectrum of disorders manifesting either as hypo or hyper functioning of the thyroid gland reflected in the circulating levels of Tri-iodothyronin (T3), Thyroxin (T4) and Thyroid stimulating hormone (TSH). The disorders of thyroid hormone can be due to diseases of the thyroid gland itself (primary), secondary to pituitary disorder (secondary) or due to hypothalamic diseases (tertiary)[4]. Congenital hypothyroidism is the most common preventable cause with worldwide incidence of 1:3000-4000. In India this ratio is 1:2500 - 2800 [2,3]. Hypothyroidism after the age of three years when most of the brain development is completed, their deficiencies leads to slow growth and delayed skeletal maturation [3].Autoimmune thyroid diseases are now major leading cause of thyroid disorders in childhood and now considered the most common cause of acquired hypothyroidism. They include Hashimoto thyroiditis and lymphocytic thyroiditis. Their clinical manifestations range from euthyroid goiter to hypo or hyperthyroid state [5,6].Hyperthyroidism is rare in children and if present it causes rapid linear growth and skeletal maturation due to increase metabolic activity [5,7].

AIMS AND OBJECTIVES

1. To Study the prevalence of thyroid disorders in children.
2. To study the etiology and clinical profile of thyroid disorders in children.

METHODOLOGY

SOURCE OF DATA -

A hospital based observational study was performed in newborns and children below 18 years fulfilling the inclusion criteria visiting the Paediatric outpatient department [OPD] and in patient department [IPD] in Ananta Institute of Medical Science & Research Centre Rajsamand Rajasthan, having clinical suspicion of thyroid dysfunction from January 2019 to December 2019(12 months).Patients having clinical features suggestive of thyroid disorders like constipation, short stature , lethargy, goiter, mental retardation, obesity, prolonged neonatal jaundice, palpitations etc were enrolled in the study. Thyroid profile consisting of TSH, free T4 and Total T4 is done if there is suspicion of hypothyroidism and in suspicion of hyperthyroidism thyroid profile consisting of TSH and free T3 is done. Patients having normal thyroid function test are not evaluated further in the study. Patients having abnormal thyroid function, which is defined as per the standard cut offs of free T3,totalT4 , freeT4 and TSH according to different age groups [38] are evaluated further in the study and taken as a positive case. Later detailed demographic data (age, sex, address) including family history of thyroid disorders, use of iodised salt, vital parameters, anthropometry , systemic examination , examination of the thyroid gland was performed. Further tests like complete blood count in cases is done. Anaemia is defined according to WHO guidelines [39]. Anaemia is graded as mild, moderate and severe depending upon the age and sex wise cut offs. USG thyroid was done in all the positive case and looked for presence of goiter. In case of suspicion of congenital hypothyroidism the patient is subjected to 99 ^{m} technetium scan.

ISSN 2515-8260 Volume 7, Issue 8, 2020

In cases of suspected autoimmune etiology tests like anti thyroid peroxidase antibodies (anti TPO) and anti thyroglobulin antibodies (anti TG) are performed in the patients. Normal reference values of anti TPO levels is < 35 IU/ml and anti TG antibody levels is < 20 IU / ml[49]. All the diagnosed patients are treated as per guidelines [31].

SELECTION CRITERIA OF THE PATIENTS:

Inclusion Criteria:

1. Newborns.
2. Children below 18 years of age.

Exclusion Criteria:

1. Patient on any medication altering the thyroid hormone status.
2. Patient in whom informed consent could not be obtained.

These 252 patients were selected from OPD and IPD having clinical suspicion of thyroid dysfunction visiting at Ananta Institute of Medical Science & Research Centre Rajsamand, Rajasthan. Of these 252, cases having abnormal thyroid function test were evaluated further.

DATA ANALYSIS AND INTERPRETATION –

Data was entered into Microsoft Excel (Windows 8; Version 2012) and analysis was done using the Statistical Package for Social Sciences (SPSS) for windows software. Descriptive statistics such as mean and standard deviation (SD) for continuous variables, frequencies and percentages were calculated for categorical variables were determined. Bar charts and pie charts were used for visual representation of the analyzed data.

RESULTS

Table 1: Distribution of Study Subjects according to the Age wise TSH Level (Prevalence)

Age wise TSH Levels	No.	Percent
Normal	217	86.1
Abnormal	35	13.9

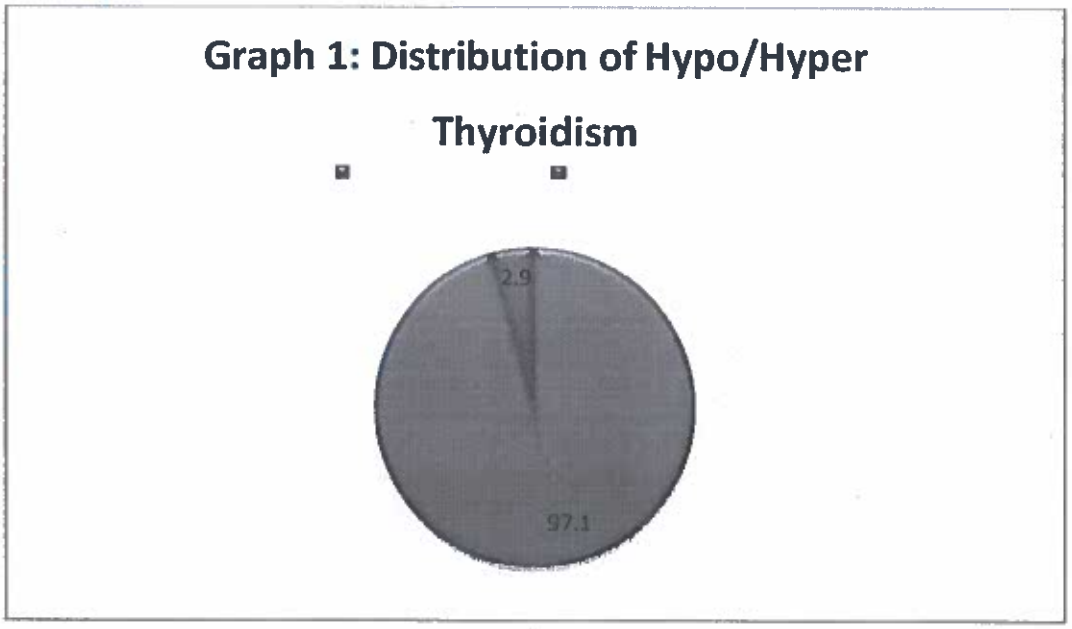
Out of 252 patients screened, 217 (86.1%) patients had normal TSH levels and 35(13.9%) patients had abnormal TSH levels. In our study, Prevalence was 13.9%. Patients with abnormal TSH were evaluated further in the study.

Table2: Distribution of Study Subjects according to the Gender (N=70)

ISSN 2515-8260 Volume 7, Issue 8, 2020

Gender	No.	Percent
Female	28	80
Male	07	20

Out of 35 cases 07 were male (20%), and 28 were female with (80%) with over all Male:Female ratio of 1:4.



Out of 35 cases, 34 cases (97.1%) were hypothyroidism and 01 cases (2.9%) was hyperthyroidism.

ISSN 2515-8260 Volume 7, Issue 8, 2020

Table 3: Distribution of Hypothyroidism Study Subjects according to Signs and Symptoms (N=34)

Chief Complaints	No.	Percent
Constipation	19	55.8
Short stature	17	50.0
Dry skin	16	47.0
Lethargy	15	44.1
Cold intolerance	13	38.2
Swelling in the neck	09	26.4
Goiter	07	20.5
Non-pitting edema	05	14.7
Fatigue	05	14.7
Developmental delay	04	11.7
Pallor	03	8.8
Abnormal weight gain	03	8.8
Polyuria	01	2.9
Umbilical hernia	01	2.9
Not gaining height	01	2.9
Delayed dentition	01	2.9
Not gaining weight	01	2.9
Bradycardia	01	2.9
Change in voice	01	2.9
Prolonged neonatal jaundice	01	2.9

Only 01 case belongs to hyperthyroidism that had increased frequency of stools, heat intolerance, hyperactivity, tachycardia, short stature, pallor & swelling of the neck.02 out of 35 cases had family history of thyroid disorders (5.7%) and 33 cases had no family history of thyroid diseases(94.2%). All the 02 were hypothyroid cases. Out of 35 cases, 07 cases had thyroid enlargement on examination (20%), 28 cases had no thyroid enlargement (80%). In our study out of 35 cases, 51.4% had height < 3rd percentile and 45.7% patients had weight < 3rd percentile.

Table 4: Distribution of Study Subjects according to the Haemoglobin (N=35)

HB (in g%)	No.	Percent(%)
Normal	11	31.4
Mild	13	37.1

ISSN 2515-8260 Volume 7, Issue 8, 2020

Moderate	08	22.8
Severe	03	08.5

Out of 35 cases, 24 cases had anaemia,13 cases with mild anaemia (31.4%), 08 cases with moderate anaemia (22.8%),03 cases with severe anaemia (8.5%), 11 cases were having normal haemoglobin levels (31.4%).Out of 35 cases, 07 cases had goiter (20%), 03 had hypoplastic features (8.5%) and 25 cases were having normal USG thyroid (7.4%).

Table 5: Distribution of Study Subjects according to Thyroid 99^{m} Technetium scan (N=07)

99^{m} technetium scan	**No.**	**Percent(%)**
Thyroid Dysgenesis	05	71.4
.-Aplasia	01	20
-Hypoplasia	03	60
-Ectopic	01	20
Dyshormonogenesis	02	28.5

Out of 07 cases with Congenital Hypothyroidism,05 cases (71.4%) are Thyroid Dysgenesis ,followed by Dyshormonogenesis in 02 cases (28.5%). In 05 cases of Thyroid Dysgenesis 03 are hypoplastic (60%) , 01 cases aplasia (20%) and 01 ectopic thyroid (20%).

Table 6: Distribution of Study Subjects according to the Diagnosis (N=35)

Diagnosis	**No.**	**Percent**
Autoimmune hypothyroidism	27	77.1
-with Goiter	07	25.9
-without Goiter	20	74.1
Hyperthyroidism	01	02.8
-without goiter	01	100.0
-with Goiter	00	0.0
Congenital Hypothyroidism	07	20
-with thyroid dysgenesis	05	71.4
-with dyshormonogenesis	02	28.6
Thyroid dysgenesis	05	
- *aplasia*	01	20
- *hypoplasia*	03	60
- *ectopia*	01	20

ISSN 2515-8260 Volume 7, Issue 8, 2020

Out of 35 cases , 27 (77.1%) are autoimmune hypothyroidism in which 20 (74.1%) cases had no goiter and 07 had goiter (25.9%), 07 (18.6%) are congenital hypothyroidism, 05 cases are Thyroid Dysgenesis (71.4%), 02 cases are Dyshormonogenesis(28.6%).Out of 35 cases, 01 cases (2.8%) are hyperthyroidism without goiter (100%). Out of 05 cases of thyroid dysgenesis, 03 cases are from Hypoplasia, 01case is belongs to aplasia & ecopia of thyroid gland

Table 7: Distribution of Study Subjects according to the Anti-Thyroid Antibodies (N=28)

Anti-Thyroid Antibodies	No.	Percent
Elevated anti-TPO	22	78.57
Elevated anti TG	24	85.71
Anti TPO positive Anti TG negative	03	10.71
Anti TG positive Anti TPO negative	05	17.85

Out of 28 cases of suspected autoimmune etiology, 22 (78.57%) cases had elevated anti TPO antibody levels, and 24 (85.71%) cases had elevated anti TG antibody levels. Out of 28 cases, 03 (10.71%) cases are positive for anti TPO antibodies but negative for anti TG antibodies where as 05(17.85%) cases are positive for anti TG antibodies but negative for anti TPO antibodies.

DISCUSSION

PREVALENCE: - Out of 252 patients tested having suspicion of thyroid dysfunction, 35 children had abnormal thyroid dysfunction, 34 were hypothyroid and 01 was hyper thyroid. Estimated Prevalence in our study is 13.88%. While results of Amitabh singh et al (2016) was 13% prevalence of thyroid disorders in children at a tertiary care hospital in western India.**MALE: FEMALE RATIO**-Thyroid disorders are well known to be more in female than male of all age groups[4]. In our study, out of 35 cases, 07 are Male (20%) and 28 are Female (80%). Overall Male: Female ratio was 1:4.In a Study done by Ian Hunter et al [40] on Prevalence and aetiology of hypothyroidism in the young noted that out of 140 cases 37 were male and 103 were female and the male to female ratio was 1:2.8.In a study done by kapil U et al [41] on Assessment of iodine deficiency in Ernakulam district, Kerala state noted that out of 1254 children between age group of 6-12 years for the prevalence of IDD in children, the male to female ratio was 1:2.9.In a study done by Meena desai[6] on Autoimmune Thyroid Disease In Childhood noted that out of 78 cases 58 were female and 20 male, the male to female ratio was 1:2.9.In a study done by R. K. Marawah et al[42] on Prevalence of thyroid diseases in children noted that out of 122 diagnosed, 14 children were male (11.47%) and 108 were female (83.52%) the male to female ratio was 1:7.7.**SIGNS AND SYMPTOMS** -In our study, out of 34 cases of hypothyroidism , the most common clinical presentation in patients is constipation (55.8%) followed by short stature (50%).In a study done by Desai MP et al [30] on disorders of thyroid gland in India noted that most common clinical presentation was constipation(87%) followed by lethargy (55%). In a study done by Amitabh Singh et al[43] on prevalence of thyroid disorders in children noted that out of 61 hypothyroid cases the most common clinical presentation was short stature (59%) followed by lethargy (49.2%).In a study done by Virmani A et al [32] on Profile of thyroid disorders in a referral centre in North India noted that the most common clinical presentation was short stature (44%).In our study, Only 01 case belongs to hyperthyroidism that had increased frequency of stools, heat intolerance, hyperactivity, tachycardia, short stature, pallor & swelling of

ISSN 2515-8260 Volume 7, Issue 8, 2020

the neck.In a study done by Amitabh Singh et al[43] on prevalence of thyroid disorders in children noted that out of 4 cases of hyperthyroidism , the most common clinical presentation was tachycardia (100%), followed by palpitations (75%).**FAMILY HISTORY:-**In our study out of 35 cases, 02 cases (5.7%) had family history of thyroid disorders .In a study done by Amitabh singh et[43] al on prevalence of thyroid disorders in children noted that 4 cases (6.5%) had family history of thyroid disorders.**GOITER:-**In our study out of 35 cases, 07 (20%) children with thyroid dysfunction had thyroid gland enlargement which was confirmed by ultrasound thyroid showing goiter.In a study done by Desai MP et al[30] on Disorders of thyroid gland in India reported prevalence of goiter in 38% children with thyroid hormone abnormalities. In a study done by R. Pradhan et al[44] on Assesment of iodine deficiency disorders in urban areas of Udaipur district Rajasthan ,India noted that the prevalence of goiter was 25%.Similarly in a study done by Shah NA et al[33]on Evaluation of thyroid diseases by hormonal analysis in Paediatric age group noted that out of 16 cases, 3 cases had prevalence of goiter (5%).**ANEMIA**:-Anaemia is known to be associated with hypothyroidism[45]. The common type of anaemia found in hypothyroidism is anaemia of chronic disease [46].In our study out of 35 cases, prevalence of anaemia was found to be 24 (68.5%).In a study done by Amitabh singh et al[43] on prevalence of thyroid diseases in children noted that the prevalence anaemia was (31.1%).While the available literature suggest the prevalence to be higher (20 -60 %)[47].**THYROID 99^{m} TECHNETIUM SCAN** -In our study out of 35 cases, thyroid 99^{m} Technetium scan is done in 07 patients, out of which 05 (71.4%) are Thyroid Dysgenesis followed by Dyshormonogenesis in 02 cases (28.5%). Out of 05 cases of thyroid dysgenesis 03(60%) have thyroid hypoplasia , 01 (20%) have aplasia and 01 (20%) case of ectopic thyroid .Where as in study done by Amitabh singh et al[43] on prevalence of thyroid disorders in children noted that thyroid scintigraphy was done in 35 patients and most common finding was dyshormonogenisis (46 %). **DIAGNOSIS:-**In our study out of 35 cases with thyroid dysfunction, 34 cases (97.1%) were hypothyroidism and 01 cases (2.8%) were hyperthyroidism.In a study done by Desai MP et al[30] on Disorders of thyroid gland in India noted that out of 800 cases 79% were having hypothyroidism and 2% were having hyperthyroidism.In a study done by Shah NA et al[33]on Evaluation of thyroid diseases by hormonal analysis in paediatric age group noted that out of 16 cases 6 cases were having hypothyroidism(37.5%) and 1 case had hyperthyroidism(6.25%).In a study done by Amitabh Singh et al[43] on prevalence of thyroid disorders in children noted that Out of 65 cases , 61 cases were having hypothyroidism (93.8%) and 4 cases were having hyperthyroidism (6.1%).In a study done by Meena P Desai and Swati karandhikar[6] on Autoimmune thyroid disease of childhood noted that Out of 77 cases, 60 children (77%), had hypothyroidism and 8 cases (10%) had thyrotoxicosis.In our study, out of 34 cases of hypothyroidism, 27 cases were autoimmune hypothyroidism (77.1%), and 07 cases were congenital hypothyroidism (19.5%).In a study done by Meena P et al[6] on Autoimmune thyroid disease in childhood noted that 40% cases were autoimmune hypothyroidism and 46% cases were congenital hypothyroidism. **ANTI THYROID ANTIBODIES-** In our study of 35 cases, 28 cases suspected of having autoimmune etiology are subjected to anti TPO and anti TG levels, 22 cases (78.57%) had elevated anti TPO antibodies and 24 cases (85.71%) had elevated anti TG antibodies. In a study done by Meena Desai et al[6] on Autoimmune thyroid disease in childhood noted that out of 96 cases, 66 cases (68.7%) were having anti thyroid antibodies positive. Anti TPO antibodies positivity were more common than anti TG antibodies. Out of 57 cases, 6 (10.52%) cases are positive for anti TPO antibodies but negative anti TG antibodies where as 11(19.29%) cases are positive for anti TG antibodies but negative for anti TPO antibodies. In study done Meena P et al[6] anti thyroid antibody levels of 1:100 were considered significant and taken as positive case. **TREATMENT**-All the cases of hypothyroidism were treated with tablet levothyroxine and hyperthyroidism cases with Carbimazole according to standard guidelines[31]. Iron, calcium and vitamin D3 supplementation was given to the patients. Review of literature reveal that in India less than 10% cases of congenital hypothyroidism are diagnosed by the age of 3 months and only about

ISSN 2515-8260 Volume 7, Issue 8, 2020

50% by the age of 2 years [34,48].lack of awareness amongst the primary health care practitioners and family physicians was one of the important reasons for delayed diagnosis [34].

CONCLUSION

Thyroid hormones estimation is very useful in diagnosis of various thyroid disorders in children with clinical suspicion of thyroid dysfunction. Thyroid hormones are unique in view of their role in fetal development and early neonatal brain development and also having actions on growth and developmental during the first two decades of life. Congenital hypothyroidism is one of the major preventable thyroid diseases if diagnosed early. Hence screening of all newborns and children should be mandatory as early diagnosis and treatment helps in prevention of mental retardation and other complications of thyroid disorders. Other thyroid diseases commonly seen in pediatrics age group are autoimmune thyroiditis, goiter and rarely hyperthyroidism. Autoimmune thyroid disorders are now emerged as a leading cause of thyroid disorders in pediatric age group. Many cases have been encountered in our study where in patients with autoimmune thyroid disorders are having anti TPO antibodies negative but anti TG antibodies positive. Out of 252 patients having clinical suspicion of thyroid dysfunction, 35 cases had thyroid function abnormalities and after subjecting these 35 patients for further tests based on the suspected etiology we found out 34 cases as hypothyroidism and 01 case as hyperthyroidis

Abstract

Introduction: Hospital-acquired diarrhea (HAD), among hospitalized children is responsible for increased costs and prolonged hospital stay and also important cause of morbidity and mortality. Especially in children Hospital-acquired diarrhea an important hazard in developed and developing countries occurring about 2–32% of admitted in pediatric wards. Children under the age of three years in developing countries experience on an average of three time of diarrhea every year. On each and every episode of diarrhea, it contributes deprivation to significant nutrition which is necessary for child growth. Patients in the hospital stay may face the additional risk of acquiring infections due to contact with other patients, contaminated hospital surfaces or healthcare workers and in low-income hospitals infection control is often less meticulous which could be higher risk. **Aim:** The main objective is to study the etiology and prevalence of hospital acquired diarrhea in children. **Material and methods:** In this study total 100 patients were included with the age between 1 to 15 years old who were admitted to the pediatric ward for reasons other than diarrhea and stayed for more than 3 days. Detail history from all the patients were noted including laboratory investigation. From each and every patient stool sample were collected in disposable clean containers and send to microbiology laboratory for processed. Several diagnostic laboratory tests were done for the detection of viral, bacterial, parasitic and fungal agents. Enzyme linked Immunosorbent assay (ELISA) were done for the detection of Clostridium difficile toxins and latex agglutination test were done for detection of human rotavirus antigen. **Results:** In this study total 100 hospitalized children between the ages 1 to 15 years old were examined. Out of these 82 children (82%) were diagnosed as hospital acquired diarrhea. out of total 100 patients majority mere male children(63%) and followed by female(37%) children. Out of total 100 children, children with the age group 1-4 years showed maximum (38%) of hospital acquired diarrhea followed by 4-8 years (29%), 8-12 years(18%) and 12-16 years(15%) respectively. **Conclusions:** This study also revealed a high prevalence of hospital acquired diarrhea our area and the infectious causes were more than the non-infectious causes, with bacterial predominance among the infectious agents. Therefore this study recommends routine general stool examination, stool culture/sensitivity for detection for microbial infection and Cl. difficile detection by ELISA methods for all patients with hospital acquired diarrhea to identify the causative agent. Hence, healthcare strategy and campaign should be focused on specific hospital staff and community area must be available.

Keywords: Children, Hospital acquired diarrhea, Enteropathogenic Escherichia coli.

Introduction

Hospital-acquired diarrhea (HAD), among hospitalized children is responsible for increased costs and prolonged hospital stay and also important cause of morbidity and mortality[1]. Especially in children Hospital- acquired diarrhea an important hazard in developed and developing countries occurring about 2–32% of admitted in pediatric wards[2,3]. Especially in the cases of children diarrheal disease is the most common disease which causes mortality and morbidity in worldwide mainly in developing countries. According to WHO about 525,000 children under five years worldwide die due to diarrheal diseases each year with 1.7 billion cases of diarrheal disease every year[4]. Children under the age of three years in developing countries experience on an average of three time of diarrhea every year. On each and every episode of diarrhea, it contributes deprivation to significant nutrition which is necessary for child growth[5]. In developed countries, long term uses of broad spectrum antibiotics may disturb normal colonic flora followed by colonization of Clostridium difficile and this may be the common cause of new onset of diarrhea among

hospitalized patients[6]. Patients in the hospital stay may face the additional risk of acquiring infections due to contact with other patients, contaminated hospital surfaces or healthcare workers and in low-income hospitals infection control is often less meticulous which could be higher risk[7,8] .Research from developed and developing countries suggest that age, length of hospitalization, immune status, nutritional status, and exposure to gastrointestinal procedures such as endoscopy and nasogastric intubation are host-related risk factors for hospital-acquired diarrhea[9,10]. For the control and spread of Hospital-acquired diarrhea from contaminated food is and main concern in hospitals and nursing homes. Due to untrained staff using unsafe practices for the storage, preparation and handling of food frequently. Furthermore quality of drinking water with limited resources is often unsafe controlling outbreaks of waterborne infectious diarrhea are continuing problem[11].The main objective is to study the etiology and prevalence of hospital acquired diarrhea in children.

Material and methods

This is a cross sectional study carried out at Ananta institute of medical science & research centre Rajsamand, Rajasthan in the department of pediatric with the collaboration of department of microbiology. In this study total 100 patients were included with the age between 1 to 15 years old who were admitted to the pediatric ward between march 2019 to February 2020 for reasons other than diarrhea and stayed for more than 3 days. For the diagnosis of the hospital acquired diarrhea in the hospitalized patients, the Centers for Disease Control and Prevention (CDC)[12] definition of hospital diarrhea was used, as in a hospitalized patient acute onset of diarrhea with a period of at least 3 days of hospitalization prior to the onset of diarrhea. Detail history from all the patients were noted including laboratory investigation. From each and every patient stool sample were collected in disposable clean containers and send to microbiology laboratory for processed. Several diagnostic laboratory tests were done for the detection of viral, bacterial, parasitic and fungal agents. Enzyme linked immunosorbent assay (ELISA) were done for the detection of Clostridium difficile toxins and latex agglutination test were done for detection of human rotavirus antigen

Results

In this study total 100 hospitalized children between the ages 1 to 15 years old were examined. Out of these 82 children (82%) were diagnosed as hospital acquired diarrhea. out of total 100 patients majority mere male children (63%) and followed by female(37%) children as shown in table no 1 below.

Table 1: showing the total no of children according to their gender

	No of Cases	Percentage(%)
Male	63	63
Female	37	37
Total	100	100

Out of total 100 children, children with the age group 1-4 years showed maximum (38%) of hospital acquired diarrhea followed by 4-8 years(29%), 8-12 years(18%) and 12-16 years(15%) respectively as shown in table no 2 below.

Table 2: showing age groups distribution of children with hospital acquired diarrhea

Age group	No of Cases	Percentage (%)
1-4	38	38
4-8	29	29
8-12	18	18
12-16	15	15
Total	100	100

Among all the patients, in 82% of the patients showed various causative agents as variety of microbial causative agents were isolated and identified and remaining 18% was no obvious causative agent detected. Out of the total single infectious agent causing 63.2% and 15.9% had mixed infections of bacterial–bacterial, bacterial–parasitic or bacterial–viral. Enteropathogenic Escherichia coli (EPEC) was most commonly isolated microbial agent 23.2% cases followed by parasitic infection 20.8% and rotavirus in 17.1% respectively. In about two- thirds of isolates, 3 organism's isolates were found. Remaining organism was found in low frequency as shown in table no 3 below.

Patients with the age group 1-4 years of age were most affected by hospital acquired diarrhea followed by age group 4-8 years. In both the age group EPEC was most predominant which is followed by Rota virus. The opportunistic microorganisms like Pseudomonas aeruginosa, Proteus mirabilis, Klebsiella oxytoca were detected in age group 1-4 years, and they represented 15% of the total isolates. In this study out of total hospital acquired diarrhea bacterial infection 58.6% were most common which is followed by parasitic infection 20.8%, viral 17.1% and fungal infection 3.7% respectively.

Table 3: Age distribution of infectious agents in stool samples of children with nosocomial diarrhea diagnosed

Infectious agent	Isolates by age group					
	1-4	4-8	8-12	12-16	total	%
Enteropathogenic Escherichia coli	5	8	4	2	19	23.2
Clostridium difficile	4	3	3	1	11	13.4
Salmonella enteritidis	0	1	2	1	4	4.9
Klebsiella oxytoca	1	0	1	0	2	2.4
Pseudomonas aeruginosa	2	3	1	0	6	7.3
Proteus mirabilis	1	1	1	0	3	3.7
Shigella flexneri	1	1	0	1	3	3.7
Entamoeba histolytica	4	2	2	1	9	11.0
Cryptosporidium parvum	2	1	1	0	4	4.9
Giardia lamblia	0	1	2	1	4	4.9
Candida albicans	2	1	0	0	3	3.7
Rotavirus	6	4	3	1	14	17.1
Total	28	26	20	8	82	100.0

Discussion

Hospital acquired diarrhea is an acute diarrhea defined by the place of infection and the time of onset after 72 hours. in order to exclude microorganisms the 3-day cut-off period is used which may be acquired from the community and stay dormant in the body without clinical evidence[13]. A study reported from northern Brazil a higher prevalence of hospital acquired diarrhea among children was about 40% which showed less than this study as it shows higher prevalence whereas in south India showed prevalence to be 20% among hospitalized children with age less that 36 months[14,15]. This difference in prevalence may be related to different factor such as hygiene practices. sanitation level of the hospitals and type of microorganisms endemic in the area. While admit in the hospital and stay for longer period in hospital with limited routine infection control that may increase the possibility of exposure to potential pathogens at hospital settings which might cause new onset of diarrhea. Moreover, in hospital many care givers had diarrhea while caring for ill patients and that also pose one of the risk factor to patients[16,17]. In this study showed that a high prevalence of cases were in children with the age below 5 years and this prevalence were agree with other studies from Iraq[18] and also from Saudi Arabia[19]. In India there are many studies which showed that the incidence of diarrhea among children in high in the age between 4 months and 2 years[20]. Many studies showed that gastrointestinal system is most frequent site as in the other general pediatric service[21]. In this study EPEC were most common isolated organism and rotavirus were most common viral agent causing infectious diarrhea in children which is also similar to the studied of Jindal et al[22]as it showed 21.4% of cases of infectious diarrhea were due to EPEC. A studied from Turkey by Oguz F et al[23] showed Cl. Difficile as 20.7% which is similar to this study. In this study period there was no clinical evidence of cholerae due to Vibrio cholerae and diarrhea with food poisoning due to Staphylococcus aureus was found. Other bacteria like Campylobacter jejuna and Yersinia enterocolitica were also not found that are sometimes involve in hospital acquired diarrhea among children.

Conclusion

In children diarrhea is very important issue in developing countries like India. This study also revealed a high prevalence of hospital acquired diarrhea our area and the infectious causes were more than the non-infectious causes, with bacterial predominance among the infectious agents. Therefore this study recommends routine general stool examination, stool culture/sensitivity for detection for microbial infection and Cl. difficile detection by ELISA methods for all patients with hospital acquired diarrhea to identify the causative agent. Hence, healthcare strategy and campaign should be focused on specific hospital staff and community area must be available.

ABSTRACT

Background: Hypomagnesemia has been associated with type 2 diabetic mellitus and is known to be a risk factor for microvascular complications. This study aimed to evaluate serum magnesium levels in patients with type 2 DM and correlate them with microvascular complications.

Materials & Methods: A hospital based cross-sectional study was conducted on150 patients with type 2 diabetes mellitus were admitted in the Mahatma Gandhi Hospital, Bhilwara, Rajasthan, India. Serum magnesium levels were assessed in all the diabetic patients and they were also tested for presence of microvascular complications.

Results: In the present study majority of the patients (71.33%) were males and male to female ratio was 2.48:1. The commonest age group was > 60 years (50%) and the mean age was 60.38 ± 10.81 years. The duration of diabetes in 45.33% of the patients was between 6 to 10 years and mean duration was 7.43 ± 4.11 years. Hypomagnesemia was associated with microvascular complications including diabetic retinopathy, diabetic nephropathy and diabetic neuropathy (p<0.050). Also, association was found between serum magnesium levels glycaemic control cnd duration of diabetes (p<0.050).

Conclusion: Hypomagnesemia is widely prevalent in patients with type 2 diabetes mellitus and a major risk factor for the development microvascular complications that is, diabetic retinopathy, nephropathy and neuropathy.

INTRODUCTION

The prevalence of diabetes is rapidly rising all over the globe at an alarming rate.[1] It is important to note that the rise in prevalence is seen in all six inhabited continents of the globe.[2] Over the past 30 years, the status of diabetes has changed from being considered as a mild disorder of the elderly to one of the major causes of morbidity and mortality affecting the youth and middle aged people.

The epidemic of diabetes is most pronounced in India as the World Health Organization (WHO) reports show that 32 million people had diabetes in the year 2000.[2] The International Diabetes Federation (IDF) estimates the total number of diabetic subjects to be around 40.9 million in India and this is further set to rise to 69.9 million by the year 2025.[3] Diabetes mellitus leads to impaired metabolism of carbohydrates, proteins, fats, water and electrolytes. The persistence of these metabolic disturbances lead to permanent and irreversible functional and structural changes in the cells of the body which in turn lead to the development of "diabetic complications", characteristically affecting, the cardiovascular system, eye, kidney and nervous system mainly.[4]

Micronutrients have been investigated as potential, preventive and therapeutic agents for type 2 diabetes mellitus and their complications.[5] In particular, diabetes has shown to be associated with abnormalities in the metabolism of zinc, chromium, copper, magnesium and manganese.[6] Out of these magnesium has been investigated as a clinically

significant electrolyte, for a long term global policy to lower the burden of diabetes mellitus, with new findings and researches.[7] Studies have shown that magnesium levels are lower in patients with diabetes compared with nondiabetic controls.[8] The reported incidence of hypomagnesemia in patients with type 2 DM varies between 13.5 to as high as 47.7%.[9]

Magnesium is the fourth most abundant cation in the human body and the second most abundant intracellular cation.[10] It plays an important role in the carbohydrate metabolism. It serves as a cofactor for all enzymatic reactions that require kinases.[11] Magnesium depletion has a negative impact on glucose homeostasis and insulin sensitivity in patients with type 2 diabetes as well as on the evolution of complications such as retinopathy, arterial atherosclerosis and nephropathy. Moreover, a low serum magnesium level is strong, independent predictor of development of microvascular complications in type 2 DM.[12]

Although, serum magnesium levels are known to be low in type 2 DM, the entity of hypomagnesemia very often remains under-diagnosed and under-evaluated due to its usual asymptomatic presentation. Also, to date, there are very few studies which have evaluated the association of serum magnesium levels with the microvascular complications especially in India. Hence, this study was planned to evaluate the serum magnesium levels in patients with type 2 DM and to correlate them with the microvascular complications.

METHODS

A hospital based cross-sectional study was conducted on 150 patients with type 2 diabetes mellitus were admitted in the Mahatma Gandhi Hospital, Bhilwara, Rajasthan, India.

Inclusion Criteria

- Patients with type 2 diabetes mellitus.
- Age more than 18 years.

Exclusion Criteria: The following patients were excluded from the study.

- Non-diabetic kidney disease
- Chronic diarrhea
- Thyroid dysfunction
- Sepsis
- Chronic alcoholics
- Pregnancy and lactation

Patients were interviewed to obtain the demographic characteristics such as age and sex, presenting complaints, diabetic history and history of other comorbid conditions. These patients were subjected to clinical examination and the findings including vitals and systemic examination findings were noted. Patients were evaluated for the features of diabetic peripheral neuropathy.

RESULTS

In this study the commonest age group for type 2 DM was more than 60 years which comprised of 50% of the patients. The mean age was 60.38 ± 10.81 years and median age was 60.5 years (Range 36-89 years). The male to female ratio was 2.48:1. The mean duration of diabetes was 7.43 ± 4.11 years.

In the present study most common presentation of complications was tingling and numbness i.e symptoms suggestive of neuropathy (28%) (Table 2).

In the present study hypomagnesemia (< 1.8 mg/dL) is seen in 58.54% of the patients with microvascular complications compared to 20.59% of the patients. This difference was statistically significant (p<0.001) (Table 3). The mean serum magnesium levels in patients with and without microvascular complications. The mean serum magnesium levels were significantly low among the patients who had complications (p<0.050) (Table 4).

Table 1: Age & gender wise distribution of cases

Age distribution (years)	Number	Percentage
18-30 years	0	0%
31-45 years	18	12%
46-60 years	57	38%
>60 yrs	75	50%
Total	150	100%
Gender		
Male	107	71.33%
Female	43	28.77%
Male: Female	2.48:1	
Duration of diabetes	7.43 ± 4.11 years	

Table 2: Clinical presentation

Clinical presentation	Number	Percentage
Tingling	42	28%
Numbness	42	28%
Nocturnal pain	6	4%
Blurring of vision	4	2.67%
Dysuria	3	2%
Puffiness of face	1	0.67%
Sensory ataxia	1	0.67%

Table 3: Association of serum magnesium level with Microvascular complication

Microvascular complications	Serum Magnesium (mg/dl)				Total	
	<1.8		1.8-2.5			
	No.	%	No.	%	No.	%
Present	48	58.54	34	41.46	82	100%
Absent	14	20.59	54	79.41	68	100%
Total	62	41.33	88	58.67	150	100%

Table 4: Comparison of mean serum magnesium levels with complications

Diabetic Complications	Serum Magnesium (mg/dl)				P-value
	Complication		Non-complication		
	No.	Mean ± SD	No.	Mean ± SD	
Overall Complications	82	1.70±0.31	68	1.92±0.25	<0.001
Diabetic Retinopathy	48	1.65±0.30	102	1.86±0.28	<0.001
Diabetic Nephropathy	54	1.70±0.27	96	1.85±0.31	0.002
Diabetic Neuropathy	48	1.62±0.31	102	1.91±0.24	<0.001

DISCUSSION

Magnesium is the fourth most abundant cation in the human body and the second most abundant intracellular cation. The low serum magnesium levels in diabetics may contribute to the evolution of diabetic complications such as retinopathy, abnormal platelet function, cardiovascular disease and hypertension via reduction in the rate of inositol transport and

subsequent intracellular depletion. Patients with severe diabetic retinopathy have lower magnesium levels than do diabetic patients with minimal retinal changes, which suggests that hypomagnesaemia may be a risk factor in development of diabetic retinopathy.[13]

It is reported that, the prevalence of diabetes higher in men than women.[14-20] The same was true in the present study as males (71.33%) outnumbered females (28.67%) with male to female ratio 2.48:1. These findings suggest higher prevalence of diabetes among males in this study which was consistent with the previous literature.[14-20]

Unlike in the West, where older persons are most affected, diabetes in Asian countries is disproportionately high in young to middle-aged adults.[14-20] However, in this study nearly half of the study population (50%) presented with age > 60 years. The next common age group was 46 to 60 (38%) followed by 31 to 45 years (12%). The findings show that diabetes mellitus was widely prevalent among elderly. The higher prevalence of diabetes among aged can be explained by the rise in the segment of geriatric population.[21]

In the present study 45.33% of the patients reported duration of diabetes between 6 to 10 years and mean duration was 7.43 ± 4.11 years. The mean duration of diabetes mellitus observed in the present study was comparable with a study by Badyal A. et al.[22] from Mullana, Ambala (Haryana) who reported duration of T2DM ranging from one month to eleven years with a mean duration of 9.91±5.06 years.

In the present study more than one fourth of the study population (42 patients) presented with tingling and numbness (28% each). The next common presentation was nocturnal pain (4%), blurring of vision (2.67%) and dysuria (2%). However, few patients (0.67% each) also presented with puffiness of face and sensory ataxia.

The reasons for the high prevalence of magnesium deficiency in diabetes are not clear, but may include increased urinary loss, due to osmotic diuresis, lower dietary intake, rampant use of loop and thiazides diuretics promoting magnesium wasting, diabetic autonomic neuropathies, impaired absorption of magnesium compared to healthy individuals. Sometimes frequent use of antibiotics and antifungals such as aminoglycosides and amphotericin in patients with diabetes may also contribute to renal magnesium wasting. Recently a specific tubular defect in magnesium reabsorption in thick ascending loop of Henle is postulated. This defect results in reduction in tubular reabsorption of magnesium and consequently hypomagnesemia. The reason for this tubular defect in diabetics in unclear. Insulin treatment has been shown to correct renal magnesium loss in diabetics.[23]

In the present study, the overall microvascular complications were significantly high in patients with hypomagnesemia that is, 58.54% of the patients with hypomagnesemia (<1.8mg/dL) had microvascular complications compared to 41.46% of the patients with normo-magnesemia (p<0.001). Further, the frequency of diabetic nephropathy (53.7%) diabetic neuropathy (79.17%) and diabetic retinopathy (64.58%) was significantly high among the patients with hypomagnesemia (p<0.050). The mean serum magnesium levels were significantly low (1.70 ± 0.31 mg/dL) in patients who presented with microvascular complications compared to diabetic patients without having microvascular complications (1.92 ± 0.25 mg/dL) (p<0.001) and similar trend was noted in patients with the individual complications.

This study reveals a strong association between hypomagnesemia and microvascular complications. Hence it could be suggested that routine surveillance for hypomagnesemia is done in patients of type 2 diabetes mellitus.

This study had certain limitations. As the study focused on incidence of hypomagnesemia and microvascular complications, other confounding variables such as demographic characteristics, clinical profile and biochemical profile could not be ascertained to the effect of hypomagnesemia on microvascular complications. Hence, further studies considering these confounding variables will focus higher accuracy of relationship between hypomagnesemia and microvascular complications in T_2DM.

CONCLUSION

Hypomagnesemia is widely prevalent (41.33%) among patients with type 2 diabetes mellitus and lower serum magnesium were seen in patients with poor control and longer duration of diabetes. Low serum magnesium is one of the additional risk factors for the development of microvascular complications in type 2 diabetes mellitus.

Abstract

Introduction: The cost of drug play important role in practice of medicine and disease outcome. In Indian market numerous brand available of generic drug. Tuberculosis is curable disease but if proper treatment not taken by patients then lead to development of drug resistance or pulmonary disability. AKT drugs used for the management of tuberculosis.

Objective: To compare and analysed cost variation in AKT drugs with different brand name for same dosage form & same active compound.

Materials and Methods: The price of the drug with same formulation and same strength (Dosage) was review from Indian drug review issue 3, 2017 (IDR) & CIMS (Apr- Jul 2017). Percentage of cost price variation and Cost ratio is analysed.

Result: High percentage of cost variation among first line AKT drugs seen with Ethambutol (474.51%) followed by Isoniazid (432.60%). Least percentage of cost variation seen with streptomycin (1.01%) followed by rifampicin (1.33%). Maximum cost ratio of first line drugs seen with Ethambutol (5.74). Among 2nd line AKT drug Maximum and least percentage of cost variation are seen with levofloxacin 500 mg tablet formulations (1550.84%) and Ofloxacin 400 mg sustained Releases - tablet (1.57%) respectively. Higher percentage of cost variation seen with more manufacture company/ no. of brand.

Conclusion: The wide percentage of cost variation is seen with AKT drugs available in Indian market. Regulation of drug price by concerned agencies and by government is needed. Rational drug prescription with low cost is important for treatment adherence and disease outcome.

Keywords: Pharmacoeconomics, Cost variation, Cost ratio, AKT drugs.

Introduction

Pharmacoeconomics identifies, measure and compare the cost and consequences of drug therapy to healthcare system and play important role in practices of medicine.[1,2] Cost of drugs is important factor for the good patient's compliances with treatment. In Indian market AKT drugs (antitubercular) drugs available are available with brand name.

Tuberculosis is cause by mycobacterium tuberculosis and it is treatable and curable disease. Globally, the best estimate is that 10.0 million people (range, 9.0–11.1 million) developed TB disease in 2017. Drug-resistant TB continues to be a public health crisis. The best estimate is that, worldwide in 2017, 558 000 people (range, 483 000–639 000) developed TB that was resistant to rifampicin (RR-TB), the most effective first line drug, and of these, 82% had multidrug-resistant TB (MDR-TB). TB is one of the top 10 causes of death and the leading cause from a single infectious agent.[3,4] AKT drugs /*is also known as antitubercular drugs use for the treatment of tuberculosis. Antitubercular drug divided into first line drugs and second line drug according to clinical utility. Tuberculosis patient divided into newly diagnosed and previously treated patient. First line drugs having high therapeutic efficacy and low toxicity used for newly diagnosed and previously treated patients. Second line drugs have a either low antitubercular efficacy or higher toxicity or both used for drug resistant tuberculosis. So, 2nd line drugs are reserve drugs.[5] treatment failure have higher morbidity and mortality compared with those who are cured as well as high rates of multidrug-resistant TB have been found among treatment failure cases especially in developing countries.[6] Obstructive ventilatory disorder is the commonly found disorder in patients with pulmonary TB.[7]

This study was planned to compare cost of various AKT drugs with same active compound (drug) and evaluate the difference in cost of various brand of same active compound (drug) with same formulations.

Materials and Methods

For this study price of the drug was review from Indian drug review issue 3, 2017 (IDR) & CIMS (Apr- Jul 2017). Difference between maximum and minimum price of the same drug (same generic name) manufactured by different company was calculated from these percentage of price variation was calculated. By using following formula percentage of price variation was calculated.[2]

$$\text{Percentage of cost variation} = \frac{\text{Price of the most expensive brand} - \text{Price of least expensive brand}}{\text{Price of least expensive}} \text{X } 100$$

Cost ratio was calculated by the ratio of the most expensive brand to least expensive brand of the same drug.[2] Cost ration and percentage of variation was calculated by entered data in Microsoft excel 2013. Permission was taken from institutional ethical committee of the American international institute of the medical sciences. Udaipur, Rajasthan.

Inclusion Criteria

1. All single molecules, Fixed drug combinations of AKT drugs manufactured by more than one company

Exclusion Criteria

1. Drug formulation manufactured by only one company.
2. Drug formulations with no price information.

In present study cost of first line drug Isoniazid, Rifampicin, Pyrazinamide, Ethambutol, Streptomycin (total number of drugs five) and second line drugs ofloxacin, levofloxacin, ciprofloxacin, moxifloxacin, ethionamide, cyclosporine, amikacin, capriomycin, prothioemide (total number of drugs nine) were analysed.

Five fixed drug combinations of first line drugs with different formulation were analysed. Second line drug like terizidone, para- aminosalicyclic acid (PAS), rifabutin, thiacetazone, cyclosporine were not match with our inclusion criteria so not included in analysis.

Result

Fluroquinolones are 2nd line AKT drugs. They are divided into first generation and second generation drugs. Ofloxacin and Ciprofloxacin are first generation fluroquinolones and levofloxacin and moxifloxacin are second generation fluroquinolones. The cost variation among fluroquinolones are shown in Table 2 and Table 3. Fluroqulinolones have different type of formulation available in market. Maximum percentage of cost variation is seen with levofloxacin 500 mg tablet formulations (1550.84%) followed by Ofloxacin 200 mg tablet formulation (1007.74%). While least percentage of cost variation seen with the Ofloxacin 400 mg sustained Releases - tablet (1.57%). Maximum cost ratio seen with levofloxacin 16.50 and minimum seen with Ofloxacin (1.01). The cost variation of Second line AKT drugs other than fluroquinolones are shown in table 4. Maximum price variation seen with amikacin (119.71%) and least cost variation seen with prothonemide so among all 2nd line AKT

drug maximum price variation seen with levofloxacin and least cost variation seen with ofloxacin.

Fixed drug combination available with different formulations and different dosage form, among them FDCs which match our criteria they are analysed. The cost variation analysis is given in table 5. Maximum cost variation seen with isoniazid and ethambutol combinations (1984.69 %). Least cost variation seen with isoniazid and rifampicin(R 450+ H 300) combination (0.43%).

Discussion

According to global tuberculosis report 2018, Tuberculosis is one of the top 10 causes of death and the leading cause from a single infectious agent & the proportion of people with TB who died from the disease was 16% in 2017.[3] According to various population-based studies there are numbers of risk factors associated with mortality following diagnosis of tuberculosis one of them is drug resistance.[8] MDR-TB is associated with an increased risk of death during treatment.[9] One of the reason for development of drug resistant TB is patient do not complete a full course of treatment.[10] So, patient adherence to the treatment is import for cure of the disease and to stop drug resistant TB.

In this Pharmacoeconomic studies result shows wide variation in the pricing of AKT drugs. First line drug which is mainly used for the treatment of TB shows wide variation in cost. High percentage cost variation seen with drug have more brand. Cost of the drug is one of the important factor for the compliance of the patients or adherence to treatment because the patient feels that the cost of therapy is a financial burden, then the compliance with therapy will be compromised.[11] Cost of the prescription rise more during last several decades. In USA for single prescription average price was $55 in 2004. The average charge over prescription was over $80, with generic product being under $40 per prescription and brand name product over $140. Reason for this rise in cost is occasioned by new technology, marketing cost and stockholder expectations.[12] This may directly affect the adherence of the treatment which affect the success of treatment. Poor adherence to the treatment decreases optimum clinical benefits and therefore reduces the overall

effectiveness of health systems.[13] According study conducted by Indrajt Hazarika around half of the patient attended privet facility for tuberculosis although AKT drugs are available free of cost under RNTCP program in government sector. Thus Role of privet sector is also important for the control of tuberculosis.[14] Pharmaceutical are not affected as all cost incurred in developing a drug/ formulations is ultimately passed on poor patients who have no choice and have to accept the drug.[15] The patients are mainly depend upon the clinician for the treatment so, whatever is prescribed they have to use it. Thus the rational prescription by clinician is important, they should prescribed low cost drug to the patients.[2] If clinician do not prescribed the higher cost formulation of drug the drug automatic out of market. So, Clinicians has greater responsibility to promote or to discourage the drug on the basis of scientific justification and rationality without influence any of pharmaceutical companies.[15]

The DPCO (Drug price control order) list of price controlled drug includes rifampicin and streptomycin from first line AKT drugs.[16] Rifampicin having low cost variation about 1% to 56% among all first line AKT drugs. Cost ratio helps to know how many times the most expensive formulation is costlier then the least expensive formulation of the same drugs.[2] In present study cost ratio of rifampicin is ranges from 1.01 to 1.56 according to different formulations and dosage of the drug which suggest lower cost ratio then other first line drugs because rifampicin is controlled drug. Ofloxacin having both high and lest price variation, reason for this may be no. of brand available as in result shows more number of brand high cost variation.[2] High cost variation seen with 200 mg tablet which is manufactured by around 90 pharmaceutical companies & least percentage of cost variation seen with 400 mg SR which is manufactured by only 2 pharmaceutical companies. The DPCO fixed the price of the drug so, once medicine included as controlled drug under DPCO, drug cannot be sold at a price higher than that fixed by the government (DPCO).[17] Thus, first line drugs used for tuberculosis treatment should be include under DPCO as controlled drug.

This study provide cost variation among AKT drugs so, advantages of the study is to cross cut out of pocket expenditure of patients on AKT drugs and that will lead to more compliance for treatment and reduce economical burden among patients.

Conclusion

The wide percentage of cost variation is seen with AKT drugs available in Indian market. High no. of brand or manufacture companies for single drug then high cost variation is seen. So, regulation of drug price by concerned agencies and by government is needed. The cost of drug is plays important role for the treatment adherence. Thus, low cost of prescription more treatment adherence. Clinician should aware about the different drug formulation with high cost variation which are available in Indian market. Privet sector also play important role in economics by rational prescribing with low cost.

Conflict of Interest: None.

Abstract
The acetaminophen induced liver toxicity is known to a substantial health problem concerning the patients with liver problems and further leads to liver transplantation. In present the therapies used for the treat APAP induced hepatotoxicity is the management with the drug named N-acetyl-cysteine (NAC) which is a sulphydryl constituent and an approved medication used to replenish the cellular glutathione storage in the liver cells. Various efforts are going on to develop innovative treatments for APAP induced liver toxicity, mainly focused on the faster recovery of liver patients and without any harmful effects. From the early 1990's the study on various herbal plants extracts, different phytochemicals and their influence on the APAP induced liver toxicity have been going on. The phytochemicals observed in the plant extracts are known to diminish the necrosis and also have a protective nature contrary to acetaminophen induced hepatotoxicity by the restoration of cellule antioxidant defensive mechanism. This further limits the oxidative stress and consequently protects the mitochondria from inflammation and impairment. On this basis, this review have summarized the herbal plant extracts which exhibit hepatoprotective properties, mechanisms etc which will help to guide and advance the existing status of herbal medicines against liver toxicity.

Keywords: Hepatotoxicity, Acetaminophen induced liver toxicity, liver transplantation, APAP, liver toxicity

Introduction

Acetaminophen (APAP) is known to be a habitually used drug for its antipyretic and analgesic properties (Lee, 2013). It is a known drug which is incorporated in the list of important medications of the WHO (World health organization) and is also an extensively used drug in the environment. APAP is advised to be highly effectual and safe analgesic as well as antipyretic medicine which should be administered in an accurate manner because of its reluctant consequences (Herndon et al., 2014). In the United States, Acetaminophen is commonly known by its brand name, Tylenol which is a derivative of *N*-acetyl-*p*-aminophenol (Nourjah et al., 2006). It is nontoxic and efficacious at recommended doses, while excessive dose may contribute to liver toxicity and subsequently leads to acute liver failure (ALF). Actually, paracetamol induced liver toxicity remains the furthermost common cause of ALF in numerous nations (Lee, 2013). About 40 years, due to the APAP toxicity there have been a 46% acute liver failure (ALF) in the US (Ostapowicz et al., 2002) alone whereas, other countries like the Great Britain and Europe have publicised a percentage level of 40 and 70% respectively (Bernal et al., 2010; Stravitz et al., 2019; Ganger et al., 2018).
Despite the evidence on the high involvement of APAP in liver failure, the mechanism of action is yet unclear. With respect to drug induced hepatotoxicity, excessive attempts had been taken in order to recognize the mechanism of its lethal consequence. A common

ABSTRACT

In this study we evaluated the effects of two ARBs, Telmisartan and Olmesartan on memory and psychomotor functions in Indian population. Material and Methods : A Prospective, comparative, randomized, before-after, open-label study was conducted at a tertiary care hospital of Ajmer. Memory functions were evaluated with PGI Memory Scale, while psychomotor functions were evaluated with Six Letter Cancellation test and Digit Letter Substitution test. Total 101 patients (SBP≥ 140 mm hg; DBP ≥ 90 mm Hg), Group I (n=52) received Telmisartan 40 mg OD and group II (n=49) received Olmesartan 20 mg OD for 16 weeks. Wilcoxon Signed Rank test and Mann Whitney U test were used. Statistical significance was considered at P<0.05. Results : A improvement in scores of memory and psychomotor functions were observed in both the groups. A statistically significant improvement (p<0.05) was shown in 3 subtests out of 10 subtests of cognitive fuctions in telmisartan as compare to Olmesartan. Both the drugs showed significant improvement in psychomotor function tests (P<0.05). Conclusion : Telmisartan showed more improvement as compare to Olmesartan.

Introduction:

Hypertension is the most important factor that negatively affects the modalities of cerebral aging[1] and is associated with cognitive compromise in aging individuals[2]. Studies have demonstrated that hypertensives exhibit reduced cerebral blood flow and metabolism (utilization of glucose to obtain energy), particularly in certain brain regions[3].Neurochemical transmission within the brain and basic cellular functions are also affected by hypertension[4].

Experimental studies suggest that treatments targeting RAS such as Angiotensin converting enzyme inhibitors(ACEIs) and Angiotensin receptor blockers (ARBs) may have beneficial effect on cognitive decline and dementia[5]. Angiotensin receptor blockers (ARBs) may have greater neuroprotective effect than ACEIs through prevention of vascular damage induced by β-amyloid[6]. They potentially and selectively inhibit effects of angiotensin II , including angiotesin II induced contraction of vascular smooth muscles, rapid and slow pressor response ,vasopressin release, increase in sympathetic tone, enhancement of nor- adrenergic neurotransmission, changes of renal function etc.[7] In this study to compare the effects of two ARBs, Telmisartan and Olmesartan on memory and Psychomotor functions in mild to moderate hypertensive patients in Indian population.

Material and Methods:

Patient selection

Patients of 20 to 70 years with both sexes male and female who were newly diagnosed as per JNC VIII[8](SBP ≥ 140 mmHg and/or DBP ≥ 90 mmHg) or were not on any antihypertensive for at least one month, having ability to understand, read, write, and communicate in Hindi with primary knowledge of English.

Exclusion criteria for the cases were patients age less than 20 and more than 70, patients known to have psychological and behavioral disorders or any other CNS disorder that could interfere with the memory and psychomotor functions and patients on any other medications (e.g. sedatives, antipsychotics, antidepressants, antihistaminic) that are known to affect memory and psychomotor functions, patients who were unwilling and did not have ability to understand, read, write, and communicate in Hindi with primary knowledge of English, Patients who have history of significant hepatic, renal, gastrointestinal, pulmonary, musculoskeletal, endocrine, neuropsychiatric, hematologic cardiovascular disease other than hypertension, Pregnant women, lactating women and any adverse drug reaction came during the study period due to drug therapy then patients supposed to be excluded from the study .

Methodology

After institutional ethical approval, a prospective, non-randomized, Observational, before-after, open label study was conducted. After sample size calculation 45 patients in each group provided 80% power, considering withdrawl during study, we enrolled 52 patients in each group. Those who met with the inclusion and exclusion criteria were enrolled in the study. Written informed consent was obtained from the patient. 3 patients were failed to come for followup so, Group I (n=52) received Telmisartan 40 mg OD , group II (n=49) received Olmesartan 20 mg OD for 16 weeks. Patient selection, treatment or drug, dose and route were solely decided by physicians from Dept. of medicine, J.L.N. Medical College and asso. hospitals.The baseline information was collected on the day zero i.e. before starting of the drug treatment. The patients were then evaluated with the help of PGI memory scale and psychomotor function tests on day zero and after 4 months. The systolic and diastolic blood pressure was recorded by the auscultatory method with the help of sphygmomanometer every fortnightly. All the cognitive functions tests were conducted in Hindi and English language. They were conducted in particular sequence and this sequence was maintained for every subject.

Tests for memory

The PGI memory scale (PGIMS)[9] was employed to assess memory function of patients. PGI memory scale consists of ten sub-tests. The subjects were explained about the test and were relaxed. The tests were done as per the instructions of PGI memory scale and scoring according to scale was done simultaneously in the following order:

Remote memory, Recent memory, Mental Balance, Attention and concentration, Delayed Recall, Immediate Recall, Verbal retention for similar pair, Verbal retention for dissimilar pairs ,Visual retention, Recognition Psychomotor function tests: [10,11]

Six Letter Cancellation Test (SLCT) and Digit Letter Substitution Test (DLST)

Statistical analysis G*Power 3.0.10 was used to calculate the sample size. Power analysis indicated that a sample size of Total 90 patients (45 per group) would give 80% power to detect differences between groups, at an α level of <0.05 and with 95% confidence interval.Statistical significance was set at P < 0.05.Data obtained in the various tests were analyzed using Graph Pad Prism 5 softwere. Analysis of distribution of data was done using the Komolgorov--Smirnov test and Wilcoxan signed rank test was used to compare cognitive and psychomotor functions at baseline and after 4 months in each group. Mann whitney U test was used to compare the pre- and post-treatment scores of memory and psychomotor functions in between groups.

Results:

Table 1 shows the age and sex distribution of patients enrolled in Telmisartan and olmesartan group. Out of them 43.56% were male and 56.44% female. As shown in table 2, Telmisartan improved cognitive and psychomotor function tests. Out 10 , 4 sub-tests were improved significantly (P<0.05) in memory function tests and improvement in psychomotor functions (SLCT & DLST) also found significant. Effect of Olmesartan on above mentioned parameters were tabulated in table 3, it shows, 3 out of 10 subtest were improved after olmesartan administration.SLCT and DLST were also significantly improved .Table 4 shows comparative analysis of two ARBs on memory and psycho-

Volume : 5 | Issue : 9 | September 2016 • ISSN No 2277 - 8179 | IF : 3.508 | IC Value : 69.48

motor function tests. A significant (P<0.05) change was observed in 3 out 10 subtests i.e mental balance, attention and concentration and recognition in Telmisartan group as compare to Olmesartan. Both the drugs showed significant improvement in psychomotor function tests (P < 0.05) but Telmisartan showed greater improvement as compare to Olmesartan, However, comparative results were not statistically significant.

Discussion:

Age and sex distribution shows (Table 1) that maximum hypertensive patients were of 60 and above in age and female (57) patients. In our study, an improvement in the scores of memory and psychomotor functions was observed in both the groups throughout the study period. Telmisartan significantly improved (P < 0.05) 4 out of 10 subtests and in comparison between two drugs, statistically significant improvement (P < 0.05) was seen in 3 out of 10 subtests of cognitive functions for telmisartan as compare to Olmesartan.Similarly , In a another study,[12] found that Telmisartan(40 mg) is associated with an improvement in cognitive functions, whereas Lisinopril (5 mg) could not provide any potential benefits to cognitive improvements after 12 weeks in metabolic syndrome patients. Swetha ES et al[13],also concluded that ARBs Losartan and Olmesartan at higher doses, Telmisartan at both lower and higher doses possess significant anti-anxiety property on elevated plus maze test. However other study, found that Pretreatment with a low dose of Olmesartan completely prevented beta-amyloid induced vascular dysregulation and partially attenuated the impairment of hippocampal synaptic plasticity in young Alzheimer's disease model transgenic mice (APP23 mice) with cerebrovascular dysfunction. Telmisartan is also reported to improve memory impairment of mice that had been intracerebroventricularly injected with Amyloid β [14] Additionally, Telmisartan partially induce PPARγ activity [15]. The PPARγ activation in the brain suppresses the inflammatory response in neuronal cells[16], endothelial cells[17], astrocytes, microglia[18]and also increases Amyloid-β clearance[19]. While,Olmesartan has low affinity towards PPARγ receptor [20].

Conclusion:

Long stayed hypertension is associated with cognitive decline. ARBs are claimed to have positive effect on cognitive performance. In present study, we observed that improvement in memory and psychomotor function tests was more with Telmisartan as compare to Olmesartan.

ABSTRACT *In this study we evaluated the effects of ARB, Telmisartan alone and with Atorvastatin on cognitive functions in hypertensives.* ***Material and Methods*** *: A Prospective, comparative, randomized, before-after, open-label study was conducted at a tertiary care hospital of Ajmer. Memory functions were evaluated with PGI Memory Scale, while psychomotor functions were evaluated with Six Letter Cancellation test and Digit Letter Substitution test. Patients (with SBP≥ 140 mm hg; DBP ≥ 90 mm Hg) devided into two groups, group I (n=52) received Telmisartan 40 mg OD and group II (n=51) received Telmisartan 40 mg OD with Atorvastatin 10 mg OD for 16 weeks. Wilcoxon Signed Rank test and Mann Whitney U test were used. Statistical significance was considered at P<0.05.* ***Results*** *: A improvement in scores of memory and psychomotor functions were observed in both the groups. A statistically significant difference (p<0.05) in both groups was shown in 2 subtests out of 10 subtests of memory functions. Both the groups showed significant improvement in psychomotor function tests (p<0.05).* ***Conclusion*** *:Telmisartan shows improvement in cognitive functions in both groups. Atorvastatin did not affect memory and psychomotor functions adversely.*

Introduction:
Studies have shown that hypertension is a risk factor for cognitive decline and dementia [1]. Angiotensin receptor blockers and Statins are frequently prescribed for cardiovascular diseases. Previous clinical studies have suggested that blockade of the RAS could prevent cognitive impairment associated with hypertension [2].Recent studies shows that angiotensin II inhibitors help to preserve cognitive functions in patients with Alzheimer's disease through a mechanism that is independent of the blood-pressure-lowering effect[3]. Relative stimulation of AT2 signaling during ARB treatment has been highlighted in terms of protection against brain damage[4]. Some ARBs like Telmisartan and Irbesartan have PPAR-γ agonistic activity[5],which is involved in prevention of brain damage by interrupting inflammatory process of brain cells[6].

Statins can also improve cognitive ability by inhibition of cholesterol synthesis[7], suppression of neurogenesis[8], increased cellular proliferation and differentiation in the dentate gyrus, also improved spatial learning[9]. But in 2014 FDA[10] released a alert that Atorvastatin can lead to cognitive impairment. The status of statins for cognitive function is still controvercial.

So, we planned to compare ARB Telmisartan alone and Telmisartan with Atorvastatin on memory and psychomotor function tests in mild to moderate hypertension.

Material and Methods:
Patient selection
Patients of 20 to 70 years with both sexes male and female who were newly diagnosed as per JNC VIII[11](SBP ≥ 140 mmHg and/or DBP ≥ 90 mmHg) or were not on any antihypertensive for at least one month, having ability to understand, read, write, and communicate in Hindi with primary knowledge of English.

Exclusion criteria for the cases were patients age less than 20 and more than 70, patients known to have psychological and behavioural disorders or any other CNS disorder that could interfere with the memory and psychomotor functions and patients on any other medications (e.g. sedatives, antipsychotics, antidepressants, antihistaminic) that are known to affect memory and psychomotor functions, patients who were unwilling and did not have ability to understand, read, write, and communicate in Hindi with primary knowledge of English, Patients who have history of significant hepatic, renal, gastrointestinal, pulmonary, musculoskeletal, endocrine, neuropsychiatric, hematologic cardiovascular disease other than hypertension, Pregnant women, lactating women and any adverse drug reaction came during the study period due to drug therapy then patients supposed to be excluded from the study .

Methodology: After institutional ethical approval, a prospective, non-randomized, Observational, before-after, open label study was conducted. After sample size calculation 45 patients in each group provided 80% power, considering withdrawal during study, we enrolled 52 patients in each group. Those who met with the inclusion and exclusion criteria were enrolled in the study. Written informed consent was obtained from the patient. One patient was failed to come for follow up so, group I (n=52) received Telmisartan 40 mg OD , group II (n=51) received Telmisartan 40 mg OD with Atorvastatin 10 mg OD for 16 weeks. Patient selection, treatment or drug, dose and route were solely decided by physicians from Dept. of medicine, J.L.N. Medical College and associated hospitals. The baseline information was collected on the day zero i.e. before starting of the drug treatment. The patients were then evaluated with the help of PGI memory scale and psychomotor function tests on day zero and after 4 months. The systolic and diastolic blood pressure was recorded by the auscultatory method with the help of sphygmomanometer every fortnightly. All the cognitive functions tests were conducted in Hindi and English language. They were conducted in particular sequence and this sequence was maintained for every subject.

Tests for memory
The PGI memory scale (PGIMS)[12] was employed to assess memory function of patients. PGI memory scale consists of ten sub-tests. The subjects were explained about the test and were relaxed. The tests were done as per the instructions of PGI memory scale and scoring according to scale was done simultaneously in the following order:

Remote memory, Recent memory, Mental Balance, Attention and concentration, Delayed Recall, Immediate Recall, Verbal retention for similar pair, Verbal retention for dissimilar pairs ,Visual retention, Recognition

Psychomotor function tests: [13,14]
Six Letter Cancellation Test (SLCT) and Digit Letter Substitution Test (DLST)

Statistical analysis G*Power 3.0.10 was used to calculate the sample size. Statistical significance was set at $P < 0.05$.Data obtained in the various tests were analyzed using Graph Pad Prism 5 software. Analysis of distribution of data was done using the Komolgorov--Smirnov test and Wilcoxan signed rank test was used to compare cognitive and psychomotor functions at baseline and after 4 months in each group. Mann whitney U test was used to compare the pre- and post-treatment scores of memory and psychomotor functions in between groups.

RESULTS:

Table-1 shows the age and sex wise distribution of hypertensives , 63.1% were female. Table-2 shows 4 out 10 subtests were improved significantly ($p<0.05$) after Telmisartan administration and 5 out of 10 subtests were improved by Telmisartan with Atorvastatin ($p<0.05$;table-3). Comparative results revealed that improvement in Delayed recall was more with Telmisartan with Atorvastatin while subtest Recognition wasimproved more in Telmisartan alone group. Both SLCT and DLST were improved significantly in group I and II. But Interdrug comparison for groups was statistically not significant ($p>0.05$; table 4).

Discussion:

In present study 4 out of 10 subtests were improved after Telmisartan administration. After Telmisartan with Atorvastatin administration, 5 subtests were improved statistically. Interdrug comparison shows significant ($p<0.05$) difference in 2 subtests out of 10 memory function tests. Comparative analysis of psychomotor function tests reveals no statistical significant ($p<0.05$) differences between groups. Angiotensin receptor blockers (ARB) improve cognitive functions by several mechanism like, increased cerebral blood flow which was decreased by activation of renin angiotensin system activation[15].prevention of accumulation of amyloid β[16].increase release of acetylcholine for neurocommunication [17].Telmisartan is also reported to improve memory impairment of mice that had been intracerebroventricularly injected with Aβ[18].

Wincewicz D & Braszko JJ,[19] found that Telmisartan diminishes deleterious effects of chronic restraint stress on memory in a statistically significant manner ($p < 0.01$) in both, PA(Passive avoidance) situation and ORT (object recognition test). So, Telmisartan may constitute a new therapeutic option in a stress-related cognitive impairment. Other researcher[20] stated that Telmisartan provides effective neuroprotection against dopaminergic cell death through PPAR-γ activation. Telmisartan protects against cognitive decline via up-regulation of BDNF/TrkB (tropomyosin related kinase B) in the hippocampus of hypertensive rat , partly because of PPAR-gamma activation independent of blood pressure-lowering effect[21].

Statins also improves memory functions by several way apart from cholesterol lowering effect,statins have shown promise in enhancing neurogenesis. Both simvastatin and atorvastatin have been shown to enhance neurogenesis in the dentate gyrus following traumatic brain injury in rats which was associated with increased vascular endothelial growth factor (VEGF) and brain-derived neurotrophic factor (BDNF) expression , increased cellular proliferation and differentiation in the dentate gyrus and improved spatial learning[9] , reduced delayed neuronal death in the hippocampus [22].

Zhao L et al,[23] found that administration of Atorvastatin ameliorated the cognitive deficits, depressed the inflammatory responses, improved the (long term potentiation) LTP impairment. It also prevents Aβ25-35-induced neurotoxicity in cultured hippocampal neurons. In contrast, another study[24] found that statins use has been associated with more cognitive impairment. So the status of statins in cognitive function is still controvercial.

Conclusion:

Improvement in cognitive functions was observed throughout the study period. Telmisartan improves cognitive functions probably due to PPARγ activity, it significantly improved ($p < 0.05$) 4 out of 10 subtests and with Atorvastatin improvement was seen in 5 out of 10 subtests of PGI memory scale which were statistically significant ($p < 0.05$). Comparative analysis shows, both the treatment groups had almost similar effect on cognitive functions. Atorvastatin does not affect memory and psychomotor functions adversely.

A Study on Critical Review of Drug Promotional Literature Using the WHO Guidelines

Archanabahen Chaudhari[1], Jitendra Zaveri[2]

[1]Assistant Professor, Department of Pharmacology, Ananta Institute of Medical Sciences and Research Centre, Rajsamand, Rajasthan, India, [2]Professor and Head, Department of Pharmacology, Ananta Institute of Medical Sciences and Research Centre, Rajsamand, Rajasthan, India

Abstract

Background: Drug promotion refers to all the informational and persuasive activities of the pharmaceuticals, which include the activities of medical representatives, drug package insert, provision of gift and samples, conducting or organize seminar, etc. However, promotion of drug by ethical way is important because it may influence the irrational drug prescriptions.

Objective: The objective of this study was to evaluate and analyze the drug promotional literature distributed by pharmaceutical companies to physicians using the World Health Organization (WHO) criteria for ethical medicinal drug promotion.

Materials and Methods: A total of 100 drug promotion literatures were evaluated collected from the various outpatient departments and evaluated according to the WHO criteria for drug promotion.

Results: Among 100 drug promotional literatures (DPLs), a total of 109 drugs were promoted. However, only 33% of DPLs gives side effect, precaution, contraindication, and warning and only 10% of DPLs gives drug interaction information. None of the DPLs fulfills all criteria of who drug promotion.

Conclusion: Information on the DPLs given only focus on the positive aspect of the drugs and not fulfill all the WHO criteria of drug promotion.

Key words: Drug promotional literature, Review, WHO

INTRODUCTION

According to the World Health Organization (WHO), drug promotion refers to "all informational and persuasive activities by manufacturers and distributors, the effect of which is to induce the prescription, supply, purchase, and/or use of medicinal drugs" (WHO 1988).[1] For the promotion of many new drugs, pharmaceutical companies are using drug promotional literatures (DPLs).[2] Many studies conducted previously concluded that increased promotion is usually associated with increased sales.[3]

All promotion making claims about drugs should be accurate, informative, up to date, and ethical. They should not contain misleading, false and biased statements (WHO 1988). Pharmaceutical companies promote their products as best and better to existing to which physician are familiar. However, many times due to inadequate, inaccurate, and false information from DPLs lead to irrational drug prescription and for physicians, many times DPLs are only source for updating their knowledge about the existing and novel drugs.[4,5]

MATERIALS AND METHODS

An observational cross-sectional study conducted by the Department of Pharmacology at Ananta Institute of Medical Sciences and Research Centre from January 2019 to March 2019. DPLs were collected from the outpatient department (OPD) of a tertiary care center attached Ananta institute of medical sciences and Research Centre from January 2019 to February 2019. Printed DPLs promoting allopathic drugs were collected from OPDs of medicine, pediatrics, skin, psychiatry, ophthalmology, obstetrics and gynecology, otorhinolaryngology, and orthopedics. 100 drug promotional literature included in the study according

Corresponding Author: Jitedra Zaveri, Ananta Institute of Medical Sciences, Rajsamand, Rajasthan, India.

to exclusion criteria. DPLs were evaluated using the WHO criteria by the following parameters:

1. The names of the active ingredients using either international non-proprietary names or approved generic names of the drugs.
2. The brand names.
3. Amount of active ingredients per dose.
4. Other ingredients known to cause problems, i.e., adjuvant.
5. Approved therapeutic uses.
6. Dosage form or dosage schedule.
7. Safety information including side effects and major adverse drug reactions, precautions, contraindications, and warnings and major drug interactions.
8. Name and address of manufacturer or distributor.
9. References to scientific literature appropriate.

Exclusion criteria: DPLs promoting.

- Drugs other than allopathic drugs,
- Medicinal devices.
- Equipment.

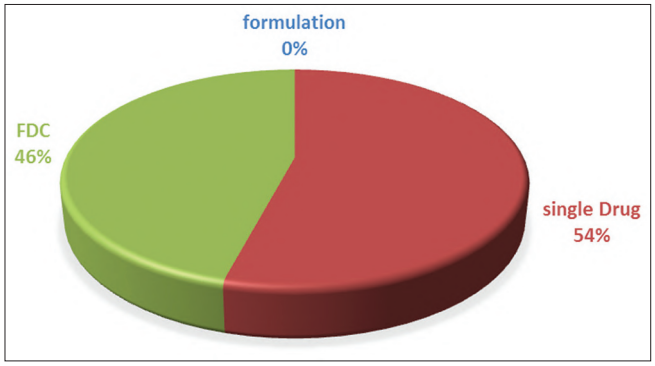

Figure 1: Distribution according to drug formulation

RESULTS

A total of 100 DPLs evaluated. A total of 109 drugs were promoted from 100 DPLs. Among them, 59 (54%) were prompted as single drug formulations and 50 (46%) promoted as fixed drug combinations [Figure 1].

Majority of drug promoted in collected DPLs were from drug act on endocrine system 36 (33%) followed by cardiovascular system 20 (18%). There were only 3% DPLs of drugs acting on kidney and 4% of respiratory system [Figure 2].

Of 100 DPLs, 63 (63%) DPLs promoted one active compound formulation and 37 (37%) DPLs promoted >1 active compound formulation [Figure 3].

None of the DPLs fulfilled all the WHO criteria. Active ingredient generic name, brand name, and dosage detail were presented in all DPLs (100%). Only 33 (33%) DPLs showed side effect and 33 (33%) showed precaution, contraindication, and warning. Few of total collected DPLs showed drug interactions 11 (11%) [Table 1].

Of 100 DPLs, 30 DPLs had not shown any references for their claim and 70 DPLs showed their references. Among 70 DPLs which provide references for their claim where consider from various National and International Journals. Some of the DPLs also had given more than 1 references. Journal references about 40% were before 2010 [Figure 4].

For attractive presentation of DPLs, companies are using picture on drug promotional literature. Of 100 DPLs, 23 (23%) DPLs not given any picture, but majority of 77 (77%) were given the picture on DPL. Among these

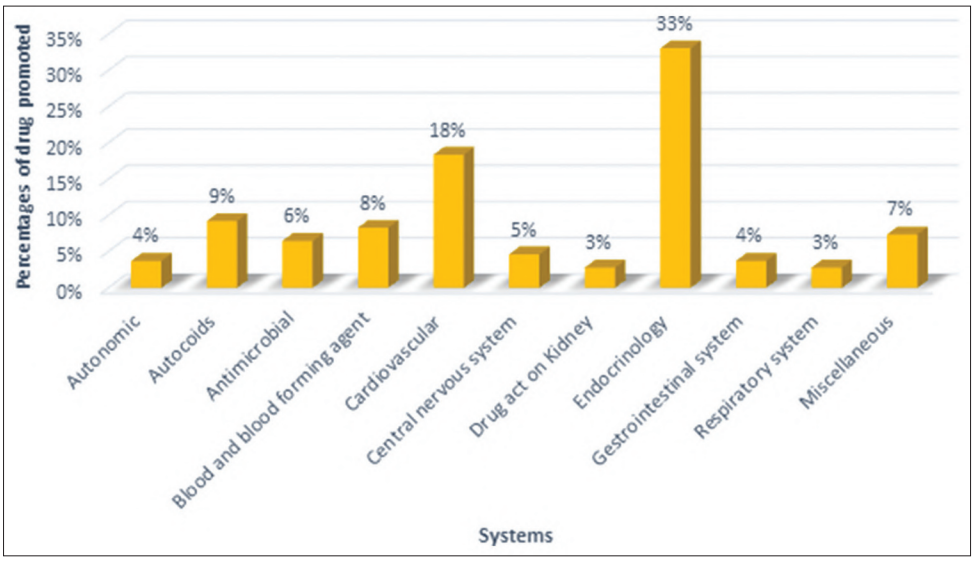

Figure 2: System-wise classification of drugs promoted in drug promotional literatures

77 literature, majority of picture were not relevant to disease and promoted drug 59 (77%). Only 18 (23%) DPLs presented with disease or drug-related picture.

DISCUSSION

The pharmaceutical industries have the right to promote its products, but it should do in ethical manner and promotional claims need to be reliable, truthful, informative, balanced, and up to date. However, while promoting their products, pharmaceutical industries do not adhere to these ethical principles it may influence irrational use of drugs.[6]

Table 1: WHO criteria for drug promotional literature

WHO criteria for drug promotional literature	Information available in DPL *n*=100 (%)
Active ingredient-generic name of drug	100 (100)
The brand names	100 (100)
Amount of active ingredients per dose	100 (100)
Other ingredients known to cause problems, i.e., adjuvant	5 (5)
Approved therapeutic uses	89 (89)
Dosage form or dosage schedule	100 (100)
Side effects	33 (33)
Drug interaction	11 (11)
Precautions, contraindications, and warnings	33 (33)
Name of manufacturer or distributor	93 (93)
Address of manufacturer or distributor	42 (42)
References to scientific literature appropriate	70 (70)

WHO: World Health Organization, DPLs: Drug promotional literatures

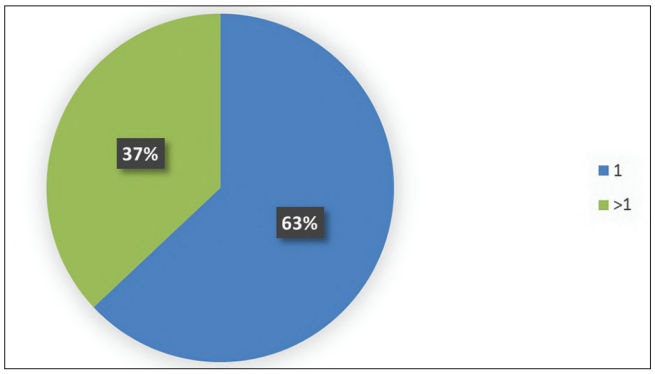

Figure 3: Distribution according to the number of drugs promoted in drug promotional literatures

In the present study, 100 DPLs evaluated. A total of 109 drugs were promoted from 100 DPLs. Of 109 drugs, 59 (54%) were prompted as single drug formulations and 50 (46%) promoted as fixed drug combinations which are similar finding as the study conducted by Jadav *et al.*, of 224 drug promoted, 54% were single component and 46% FDCs.[4]

In the present study, drug promoted from collected DPLs, majority of drug promoted in from drug act on endocrine system 36 (33%). In other studies, chemotherapy agents and cardiovascular drugs are promoted more which was different from the present study.[2,7]

In our studies show that none of the DPLs fulfill the WHO criteria which is similar finding as other studies.[2,7,8,9] Active ingredient that is generic name, brand name, and dosage detail were presented in all DPLs (100%), but other prescription information such as side effect precaution, contraindication, and warning were presented only on 33% of DPLs, drug interaction presented only in 11% of DPLs. This information is very important for rational use of drug but not available in majority of the DPLs. The study conducted by Sonwane *et al.* same shows that side effect, major drug interaction, precaution, contraindication, and warning were mentioned in only 31% which is also match with other studies.[8]

Of 100 DPLs, among 70 DPLs, majority of reference are from journal articles (93%), but among them 40% of references from before 2010. Hence, recent data about product are not given. Moreover, catchy words such as "best one" and "the only" are not available in given references. DPLs are colorful and attractive, but the picture provided on it majority were not related with disease and promoted drug.

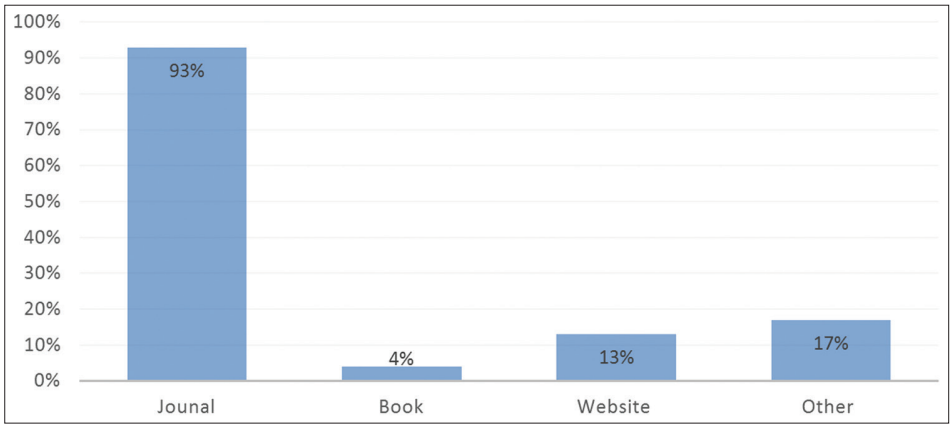

Figure 4: References given in drug promotional literatures

CONCLUSION

None of the Drug promotional literatures fulfilled all criteria of WHO for drug promotion. Promotion mainly focuses on the positive aspect of drug not the negative aspect such as side effects, contraindications, and drug interaction.

ABSTRACT

Background: Pharmacovigilance program of India plays an important role for monitoring of adverse drug reaction (ADR) in patients. However, due to lack of knowledge about pharmacovigilance among health-care professionals, underreporting of ADR observed. **Aims and Objectives:** This study aims to involve, inspire, and encourage the nursing staff to report error – free adverse drug event that meets both the needs and legitimate expectations. **Materials and Methods:** A predesigned questionnaires based cross-sectional study conducted by the Department of Pharmacology among nursing staff working at tertiary care hospital. Participants were given pre-test and post-test with ADR form filling before and after educational Interventional lecture, respectively. For data analysis, Chi-square with yet correction was applied. **Results:** A total of 30 nursing staff participants involved in questionnaires based study. An overall knowledge about pharmacovigilance ranging from 10% to 53% which was lower rang except knowledge about what is ADR was 83% in pre-test. Positive attitude toward pharmacovigilance also low ranges from 23% to 53%. Only 12% of participants were report the ADR. Majority of participant had obtained average score in ADR form filling. After educational intervention, improvement seen in knowledge, positive attitude and majority of participants fall under good score for ADR form filling. **Conclusion:** Improvement in knowledge and attitude was seen after educational intervention for pharmacovigilance among nurses.

KEY WORDS: Pharmacovigilance; Knowledge; Attitude; Practice; Nurses

INTRODUCTION

Pharmacovigilance, according to the World Health Organization, is defined as "the science and activities relating to the detection, assessment, understanding, and prevention of adverse effects or any other drug-related problems."[1] Pharmacovigilance Programme of India (PvPI) initiated nationwide in July 2010 by Central Drugs Standard Control Organization. IPC Ghaziabad is the national coordinating center for monitoring adverse drug reaction (ADR) in the country to safeguard public health. Majority of the health-care professional are not aware about this development. Hence many times, they are not reporting or late reporting of ADR.[2]

Early reporting and rapid dissemination of information regarding ADRs are two important tasks in pharmacovigilance. Voluntary reporting of ADRs by health-care professional can make the above task easy. Reason for underreporting is lack of training and awareness of this issue like where to report and whom to report as is shown by the poor knowledge of the health-care professionals, especially the nursing staff. Motivation and training of health-care professional toward pharmacovigilance will improve ADR reporting.[3,4]

MATERIALS AND METHODS

A questionnaire-based cross-sectional study conducted by the Department of Pharmacology in nursing staff working at Ananta Institute of Medical Sciences and Research Center, Rajsamand, Rajasthan. A total of 30 nursing staffs were involved. Questionnaires were pre-designed. Initially, pre-knowledge, attitude, and practice (KAP) questionnaires were given to all nursing staff after that a one hour interventional lecture was given which includes detail about ADRs and PvPI. After completion of interventional lecture, a workshop for how to fill-up ADR form conducted. Initially, in workshop, one ADR patient case was given and then nursing staff fills the ADR form. After that, they taught about how to fill-up the ADR form. After completion of interventional lecture and workshop, post-KAP questionnaire and ADR form were given to participants. Pre-test and post-test data were analyzed using Chi-square test with yet correction from website *quantpsy.org.* ADR filling form analysis was done using Microsoft Excel 2013.

RESULTS

The KAP study on pharmacovigilance before and after interventional lecture and workshop was done on the nursing staff of this institute. In this present study, a total 30 nurses were participated and fill-up pre- and post-test questionnaires and ADR reporting form.

Assessment of Knowledge toward Pharmacovigilance Pre- and Post-test – Educational Intervention

Knowledge about the pharmacovigilance assessed using questionnaires listed in Table 1. Out of 30 participants, only 16 (53%) heard about the pharmacovigilance. Only 8 (27%) participants know what is pharmacovigilance? (Correct definition of pharmacovigilance). Majority of participants 25 (83%) know about the ADR. Only 15 (50%) know who can report the ADRs. Among all participants, only 3 (10%) know about the location of national coordinator center of PvPI and only 8 (30%) know about the regulatory body of PvPI in India. About 12 (40%) participants know about the pharmacovigilance committee in this institute. After educational interventional lecture the knowledge of participants significantly increased and that was statistically significant ($P < 0.5$) [Table 1].

Assessment of Attitude toward Pharmacovigilance

Attitude toward pharmacovigilance is assessed by questionnaires listed in Table 2. Out of 30 participants, 13 (43%) believe that ADR reporting is professional obligation. Only 8 (27%) participants believe in necessity of ADR reporting, but after educational interventional lecture, majority of participants 29 (97%) believe in necessity of ADR reporting. About half of the participants 16 (53%) think that ADR reporting increase patient safety. Only 7 (23%) participants say that ADR monitoring center

Table 1: Knowledge about pharmacovigilance pre- and post-test analysis

Knowledge questions	Correct response		*P*-value
	Pre-test *n*=30, *n* (%)	Post-test *n*=30, *n* (%)	
Have you ever heard about the name pharmacovigilance program of India?	16 (53)	30 (100)	<0.5
What is pharmacovigilance?	8 (27)	27 (90)	<0.5
In general, what is ADR?	25 (83)	26 (87)	<0.5
Health-care professional responsible for reporting ADR in a hospital is/are?	15 (50)	29 (97)	<0.5
PvPI monitoring center (National Coordination Center) located at	3 (10)	26 (87)	<0.5
Name the regulatory body of PvPI in India	9 (30)	25 (83)	<0.5
Is any pharmacovigilance committee in your hospital/college?	12 (40)	29 (97)	<0.5

ADR: Adverse drug reaction, PvPI: Pharmacovigilance Programme of India

Do you think ADR reporting is a professional obligation?	13 (43)	22 (73)	<0.5
Do you think ADR reporting is necessary?	8 (27)	29 (97)	<0.5
Do you think ADR reporting will increase patient safety?	16 (53)	27 (90)	<0.5
What is your opinion about establishing ADR monitoring center in every hospital? Should in every hospital Not required in hospital	7 (23)	24 (80)	<0.5
Do you think pharmacovigilance should be taught in detail to health-care professionals?	12 (40)	25 (83)	< 0.5

ADR: Adverse drug reaction

Table 3: Analysis of practice for pharmacovigilance

Practice questions	Pre-test (%)
Have you ever seen ADR during clinical posting?	26 (86)
Have you ever-reported ADR?	4 (12)
What is reason for not reporting?	12 (40)
(a) Not aware about the presence of ADR monitoring center	18 (60)
(b) Did not know how to report ADR	

ADR: Adverse drug reaction

Table 4: ADR form filling analysis

ADR reporting form score	Pre-test (%)	Post-test (%)
Poor score	5 (25)	1 (5)
Average score	16 (80)	5 (25)
Good score	7 (35)	14 (70)
Excellent score	2 (10)	10 (50)

ADR: Adverse drug reaction

requires in every hospital. About 12 (40%) participants think that pharmacovigilance should be taught in detail to health-care professionals. Change in positive attitude toward pharmacovigilance seen after educational interventional lecture which was statistically significant ($P < 0.5$).

Assessment of Practice of Pharmacovigilance

Practice of pharmacovigilance assessed by questionnaires listed in Table 3. Out of 30 participants majority of participants 25 (83%) had seen ADRs, but only 5 (17%) participants report ADRs. Among all participants, majority of participants 18 (60%) give a reason for not reporting ADR was they were not knowing how to report an ADR.

ADR Reporting Form Filling

ADR reporting form filling was done by participant before and after workshop. Analysis of ADR form filling was done by total scoring from 20 marks. If obtained marks were between 1 and 5, then it categorized poor scoring, 5–10 marks then average score, and 10–15 score then good score, and between 15 and 20 marks then excellent score. Detail of analysis is given in Table 4. During pre-test, majoring of participants fall under average score 16 (80%) after workshop for ADR form filling majority of participants fall under good score 14 (70%) [Table 4].

DISCUSSION

Lack of knowledge about the pharmacovigilance is one of the factors responsible for the underreporting of ADR.[5,6] Voluntary ADR reporting by health-care professional play a key role for success of pharmacovigilance.[7] Nursing practices mainly come under administration of the drug. The administration of medications to the patients is one of the most common routine procedures in the practice of nursing professionals. In this, the nurse assumes the important responsibility that aims to ensure patient safety through the safe and accurate administration of prescribed medication.[8]

Nurses having an important role in pharmacovigilance activities, particularly identifying ADR in patients and they are available round the clock with indoor patients. However, lack of knowledge about the pharmacovigilance and lack of external motivation by the institute to report ADR influence the underreporting by nursing professionals.[8,9] This study was planned for improvement in knowledge and attitude and practice for pharmacovigilance by nursing staff that will improve patient safety.

The present study shows that half of the participants have knowledge about who can report ADR, only 27% of participants know about what is pharmacovigilance and only 30% know about the regulatory body of PvPI in India, after educational interventional lecture, improvement in knowledge is seen 90% and 85%, respectively. A study conducted by Goel shows that only 30.6% of participants know about pharmacovigilance, 25% of participate know about regulatory body of pharmacovigilance program and after educational intervention improvement in 99% and 86%, respectively, seen which is comparable to our study.[10]

The present study shows that of 30 participants, 43% believe that ADR reporting is professional obligation. However, positive response improves to 73% after educational intervention. Only 27% of participants give positive attitude toward the necessity of ADR reporting, but after educational intervention, majority of participants (97%) give positive attitude for the same. A study by Goel shows comparable results for the same about 29.6% before and after educational intervention 97.9%, respectively.[10] About half of the participants (53%) think that ADR reporting increases patient safety which was change to positive attitude for 90% of participants for the same.

The present study seen that majority of participants (83%) seen ADR in clinical posting, but only few participant reports the ADR (12%), the result of the study conducted by Vural *et al*. shows that only 8% of nurses report the ADR which is comparable to our study.[11] Majority of participates give a reason for not reporting ADR was do not know how to report ADR.

The present study shows significant improvement in knowledge and attitude in post-test after educational intervention and also shows improvement in ADR form filling. KAP studies for pharmacovigilance concluded that nurses having lack of knowledge and poor practice regarding the pharmacovigilance so need of regular interventions like workshop about pharmacovigilance needed.[12,13]

CONCLUSION

Improvement in knowledge and attitude after educational intervention of pharmacovigilance was seen among nurses. This indicated ADR training workshop, detail of pharmacovigilance during undergraduate course will be useful to improve KAP among nursing professionals which is helpful for patient safety through pharmacovigilance program.

ABSTRACT

Background: Hypertension (HT) posing a major public health challenge to the universe in socioeconomic and epidemiological transition. Hyperuricemia in HT is coupled with augmented cardiovascular morbidity and mortality. It also predates the development of HT and suggests that it is not simply a consequence of HT *per se*. Increased urate level along with greater production of oxygen-free radical and augmented oxidative stress may contribute to progression of HT. **Aims and Objectives:** This study aims to assess the correlation between serum uric acid (SUA), serum malondialdehyde (S. MDA) level, and blood pressure in early essential HT. **Materials and Methods:** In this cross-sectional study, after applying inclusion and exclusion criteria, 200 subjects were divided into three groups: 50 subjects as control group, 75 in prehypertensive group, and 75 in hypertensive group. SUA and S. MDA level were estimated in all subjects. Data were analyzed by appropriate statistical methods. **Results:** A significant and positive correlation was observed between SUA and S. MDA level in HT group. Both parameters were correlated positively and significantly with systolic blood pressure (SBP), but not with diastolic blood pressure (DBP) in hypertensive individuals. **Conclusion:** An elevated SUA level is predictive for the evolution of both HT and coronary artery disease. Hyperuricemia plays a role in the formation of free radicals and oxidative stress through increased lipid oxidation. Furthermore, positive correlation with SBP further established its potential role in the etiopathogenesis of essential HT.

KEY WORDS: Essential Hypertension; Hyperuricemia; Serum Malondialdehyde Level; Lipid Peroxidation; Oxidative Stress

INTRODUCTION

Essential hypertension (HT) is being increasingly documented as a part of a complex multifaceted disorder worldwide due to its high incidence and associated risks of renal and cardiovascular disease (CVD), for instance, stroke, myocardial infarction, and heart failure. The effective union between HT and hyperuricemia has been documented for more than a century. Studies from the 1950s and 1960s demonstrated the incidence of hyperuricemia in hypertensive cases to be between 20 and 40%.[1] Later on, it was found that an increasing level of serum urate is an autonomous risk factor of HT.[2]

Raised serum uric acid (SUA) level is also associated with increased cardiovascular morbidity and mortality rate.[3] Its level is thoroughly controlled by the balance among uric acid production and excretion.[4] Urate is freely filtered in the glomerulus, reabsorbed, secreted, and then again reabsorbed in the proximal tubule. Essential HT may also be linked with hyperuricemia with normal renal functions.[5] Hyperuricemia (>5.5 mg/dl [330 μmol/L]) was detected in almost 90% of teenagers with primary HT, whereas uric acid levels were

significantly lower in controls and youth with any white coat or secondary HT.[6] The finding that uric acid levels were not lifted in secondary HT also cuts down the probability that the hyperuricemia resultants from HT.

There are abundant reports that oxidative stress is amplified in patients with HT. Further, the extreme production of reactive oxygen species (ROS) due to raised urate level, out stripping antioxidant defense mechanisms, has been involved in pathophysiological conditions that influence on the cardiovascular system.[7] Moreover, ROS react with membrane lipids to yield lipid hydroperoxide, a destructive process known as lipid peroxidation. Lipid hydroperoxide decomposes to build various products containing malondialdehyde. In the present study, serum malondialdehyde (S. MDA) was used as a biochemical marker for the assessment of lipid peroxidation.

The significance of both SUA and S. MDA level in the development of essential HT has not been thoroughly investigated, especially in Southern Rajasthan. Hence, this study has been designed to study the correlation between SUA, S. MDA level, and blood pressure among newly diagnosed essential HT.

MATERIALS AND METHODS

This cross-sectional case–control study was conducted among 200 subjects in the Department of Physiology, Geetanjali Medical College and Hospital (GMCH), Udaipur. All the subjects were chosen randomly from medicine outpatient department, family members or attendants of established hypertensive patients, individual's comings to hospital for health checkup, and healthy volunteers such as clinical and non-clinical staff of a tertiary care hospital. This study was ethically approved by the institutional ethical committee of GMCH, Udaipur (Ref. No. GU/UCE/EC/2013/299 dated15/05/2013).

Inclusion Criteria

All the sex-matched subjects, aged between 20 and 50 years old were broadly divided into three groups:

- 50 participants with normal blood pressure (systolic blood pressure [SBP] = 90–119 mmHg and diastolic blood pressure [DBP] = 60–79 mmHg) were taken as control group
- 75 cases of prehypertension (preHT) (SBP = 120–139 mmHg and DBP = 80–89 mmHg) were taken as preHT group
- 75 cases of newly diagnosed cases of essential HT (SBP = 140–159 mmHg and DBP = 90–99 mmHg) were taken as HT group.

Exclusion Criteria

The subjects suffering with gout, diabetes mellitus, gestational HT, and/or secondary HT caused by renal disorders, metabolic disorders, fluid volume disturbances, endocrinal disorders, etc., were excluded from the study groups. Smokers, alcohol consumers, and patients on medication for HT were also excluded from the study. After diagnosis, a written informed voluntary consent was taken from all the participants after explaining their participation in the study in their local language. All the data from three groups were collected in the detailed pro forma along with required physical examination. For biochemical analysis, blood sample (5 ml) was drawn after an overnight fasting (12 h) by venous puncture and serum was separated by centrifugation at 3000 rpm for 10 min. SUA level and S. MDA were estimated using commercially available reagents or kits.[8,9]

Statistical Analysis

The data were analyzed using the Statistical Package for the Social Sciences (SPSS) version 16. Significance testing of difference for mean of three groups was done by analysis of variance test (ANOVA). $P < 0.05$ was used to establish statistical significance. The correlation between different parameters was assessed by Pearson coefficient of correlation test.

RESULTS

Figures 1 and 2 showing that the difference in mean of SUA level and S. MDA level between control, preHT, and HT group was highly significant ($P < 0.0001$). Table 1 shows that SUA level was significantly and positively correlated with SBP

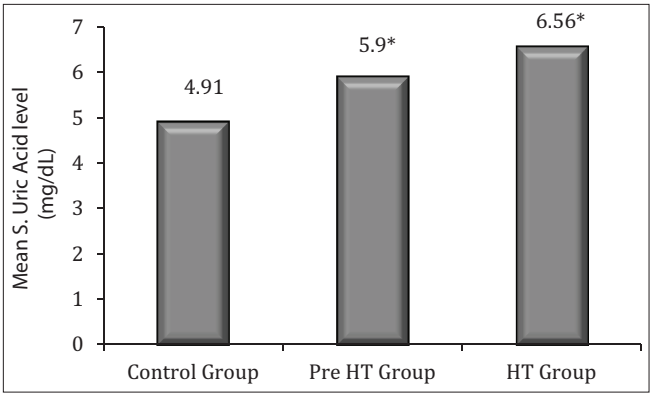

Figure 1: Comparison of mean serum uric acid level among different groups (*significant with $P < 0.001$)

Table 1: Correlation of serum uric acid levels with various parameters

Parameters	Control group		Hypertension group	
	r value	*P* value	*r* value	*P* value
SBP	−0.234	NS	+0.478	<0.001
DBP	−0.230	NS	+0.202	NS
S. MDA	+0.236	NS	+0.574	<0.001

S. MDA: Serum malondialdehyde, SBP: Systolic blood pressure, DBP: Diastolic blood pressure

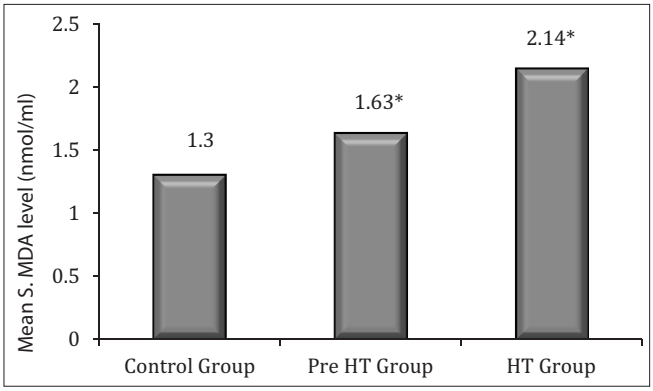

Figure 2: Comparison of mean serum malondialdehyde level among different groups (*significant with $P < 0.001$)

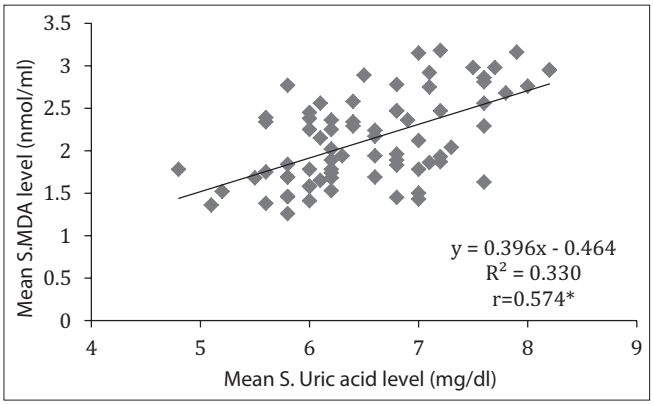

Figure 3: Correlation between serum uric acid levels and serum malondialdehyde levels (*significant with $P < 0.001$)

(r = +0.478, $P < 0.001$) and S. MDA (r = +0.574, $P < 0.001$), whereas no significant correlation was found with DBP ($P > 0.05$). Figures 3-5 showed that S. MDA was significantly and positively correlated with SBP (r = +0.486, $P < 0.001$) and SUA (r = +0.574, $P < 0.001$), whereas no significant correlation was found between S. MDA and DBP ($P > 0.05$).

DISCUSSION

In this study, we found that the mean of SUA level and S. MDA level in hypertensive group was significantly higher as compared to prehypertensive and controls ($P < 0.001$). The increased trend in mean SUA level was observed from control to prehypertensive and prehypertensive to hypertensive cases [Figures 1 and 2]. Results also showed that SUA and S. MDA were significantly and positively correlated with each other and SBP ($P < 0.001$), whereas no significant correlation was observed with DBP ($P > 0.05$) for the same.

Masuo *et al*. assessed the linear relationship of SUA and SBP and showed an average raise of 23 mmHg per 1 mg/dl increase in SUA within non-obese young men.[10] Another study on 125 children (age group 6–18 years) with essential HT proved the association of SUA with SBP (r = 0.80) and DBP (r = 0.66).[6] In support to our study, Acharya and Mishra found that S. MDA level was significantly and positively correlated

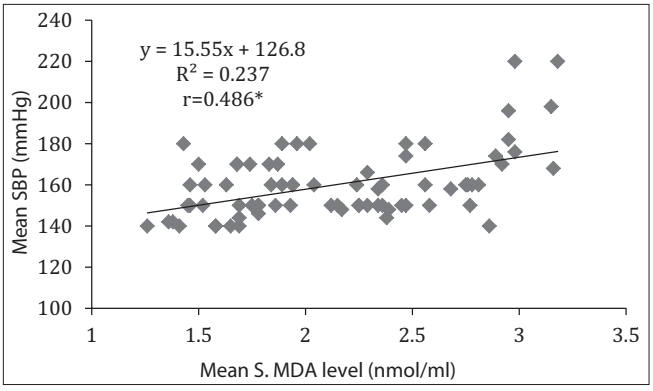

Figure 4: Correlation between serum malondialdehyde levels and systolic blood pressure (*significant with $P < 0.001$)

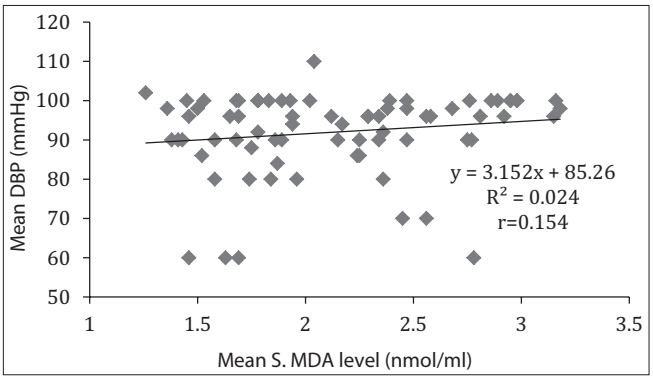

Figure 5: Correlation between serum malondialdehyde levels and diastolic blood pressure (*significant with $P < 0.001$)

with SBP (r = +0.364, $P < 0.01$) and SUA level (r = +0.289, $P < 0.05$). They found no significant correlation between S. MDA and DBP.[11] Amirkhizi *et al*. assessed the oxidative stress marker related to atherosclerosis in prehypertensive women. Regarding MDA level, they attained that MDA was positively correlated with both SBP (r = +0.24, $P < 0.001$) and DBP (r = +0.18, $P < 0.001$).[12] Ouppatham *et al*. examined the relationship of hyperuricemia and blood pressure in the Thai army population and observed a significant and positive correlation between both SUA levels and SBP (r = 0.186, $P < 0.001$) and same with DBP (r = 0.255, $P < 0.001$).[13] However, Teng *et al*. described a contrary result, wherein uric acid was associated with the risk of HT in the elderly.[14]

Hyperuricemia is commonly experienced with essential HT, even untreated HT. Studies in animal models proposed that hyperuricemia may be predominantly important in early HT[15] and likewise studies in humans illustrated that the strongest relationship of hyperuricemia is with premature HT such as discovered in adolescents.[6] Contrary to these findings, a number of studies have recommended that the association between elevated SUA and cardiovascular risk does not carry on after rectifying for other risk factors.

Experimental studies provide a credible physiologic mechanism by which increases in SUA might cause HT. Uric acid enters vascular smooth muscle cells, where it stimulates

mitogen-activated protein kinases, cyclooxygenase-2, and platelet-derived growth factor to stimulate vascular smooth muscle proliferation and preglomerular arteriolopathy.[15,16] Increased SUA further causes an increase in juxtaglomerular renin production and a decrease in macula densa neuronal nitric oxide (NO) synthase expression, leading to renal vasoconstriction and probably increasing blood pressure.[17] If renal vasoconstriction persistent, it may impart to arteriosclerosis and the exploitation of salt-sensitive HT, even if the hyperuricemia is rectified.

In addition, SUA plays a role in the formation of free radicals and may elucidate the link between hyperuricemia and HT.[18] Augmented intracellular uric acid may accelerate oxidative stress directly by raising NADPH oxidase linked ROS or generated by stimulation of xanthine oxidase during the generation of uric acid as well. Oxidative stress may contribute to the generation and/or development of HT through a number of probable mechanisms included (a) curbing of the vasodilator NO by ROS such as superoxide, (b) production of vasoconstrictor lipid peroxidation products, (c) diminution of tetra hydrobiopterin (BH4), an important NO synthase cofactor, (d) structural and functional changes within the vasculature.[19]

Experimentally, by means of which, hyperuricemia results in HT are by way of oxidative stress, endothelial dysfunction, and activation of the renin angiotensin system. The net effect is to provoke renal and systemic vasoconstriction and the progression of HT. Increase in SUA has been demonstrated as an earlier marker of HT, which occurs even before the modification in serum creatinine.[18]

Limitations

As the present study is hospital-based case–control study, so to establish these results to the population of Southern Rajasthan, large sample size should be taken.

CONCLUSION

From the above discussion, it can be concluded that increased serum MDA in hypertensive indicates an association between increased oxidative stress and HT. SUA through lipid peroxidation might be processing toward the etiopathogenesis of essential HT even in its former stages, and its serum level may be a modifiable factor for progression of the disease. Measuring these biomarkers in clinical practice may identify high-risk individuals. Further, the maintenance of the oxidative balance and SUA in hypertensive patients would be helpful in preventing the CVD and other diseases associated with HT.

Abstract

According to WHO estimates, 16.7 million people around the globe die of cardiovascular disease each year. Economic transition, urbanization, industrialization and globalization bring about life style changes that promote heart disease. High blood pressure, high cholesterol and obesity are likely to become more prevalent in developing countries. Increased energy intake and sedentary lifestyle are also responsible for heart disease. The presence of one or more cardiovascular risk factors like high levels of TC, LDL, TG, glucose, insulin, BMI and a decreased HDL have been found to increase the progression of prehypertension to hypertension. Prehypertension increases the risk of MI and CAD. The present study was undertaken to know serum lipid profile changes in reproductive and postmenopausal women. Total 60 Subjects of age group 20-45years (reproductive), 46-60years (postmenopausal) female volunteered for our study. During the study period, BMI, Lipid profile, parameters were recorded in all the subjects. In BMI, TC, LDL, VLDL, TG, is gradually increased, HDL is gradually decreased from reproductive age women to post menopausal women. Dyslipidemia occurs due to multifactorial reasons like physical activity, life style, diet, smoking, alcohol consumption, ethnicity and genetic makeup. Post-menopausal women are at increased risk of developing cardiovascular disease due to change in the lipid pattern and loss of cardioprotective effect of estrogen. Predicting the factors affecting the lipid profile in post-menopausal women, adopting strategies to control these mechanisms by modifying the relative risk factors during menopausal transition may improve the cardiovascular risk profile in these women.

Keyword: Lipid profile, Menopause, Reproductive age group.

Introduction:

Menopause is the cessation of menstrual cycle in women. It represents a transitional phase in the natural biological woman's age, a natural event that marks the end of the reproductive years of women in terms of the menstrual cycle permanently stopped and the resulting stop ovarian function in females [1]. Most of the women at this stage suffer from a variety of symptoms due to hormonal changes and these symptoms are possible to be severe and frequent, some women have more severe symptoms and others do not suffer from any symptoms at all [2]. Menopause is an oestrogen deficient state characterised by permanent amenorrhoea lasting for a period of 1 year due to the cessation of ovarian functions.[3] There is considerable variation in the level of estrogen in postmenopausal women occurs during the early postmenopausal years because of continued secretion of estradiol from the ovary and conversion of androstenedione to estrone in fat tissue.[4] In young women, where oestrogen production is high, serum lipids are normal but after menopause, lipid levels are increased resulting in increased incidence of coronary heart diseases. This shows the possible relationship among oestrogen, normal lipid profile and atherosclerosis and the relative immunity to coronary artery diseases (CAD).[5] Natural menopause confers a 3 fold increase in CAD risk and postmenopausal women account for > 30% of the female population at risk for CAD in India.[6,7]. Circulating Serum Cholesterol, Low Cholesterol (LDL-C) and Serum Triglycerides are major

risk factors of this disease. The incidence of cardiovascular disease after menopause may partly be due to changes in the plasma lipid level that occurs following menopause.(8,9) The modification of profile may be important both in the prevention and control of coronary heart disease(10) . Estrogen leads to the increased risk of cardiovascular diseases after menopause, as evidenced by reduction in the cardiovascular diseases after hormone replacement therapy. Estrogen replacement therapy, through an effect on the blood vessel wall and on serum lipids, also appears to stabilize existing atherosclerotic plaques. Antithrombotic therapy, exercise and smoking cessation also contribute to reduced risk of cardiovascular disease in older women(11). In order to contribute to the better understanding of lipid profile status in postmenopausal women, the present study was conducted to estimate the serum levels of total cholesterol (TC), triglyceride (TG),high density lipoprotein cholesterol (HDL-C), low density lipoprotein cholesterol (LDL-C), very low density lipoprotein cholesterol (VLDL-C), and atherogenic index and compare it with premenopausal women.

Material and Methods:

The present study was undertaken to know serum lipid profile changes in reproductive and postmenopausal women. Healthy subjects with no evidence of metabolic or endocrinal abnormalities, hypertension or coronary heart disease were selected randomly for reproductive and post menopausal age group consisting of 30 subjects in each group .Total 60 Subjects of age group 20-45years (reproductive), 46-60 years (postmenopausal) female volunteered for our study. During the study period, anthropometric, biochemical dietary intake and physical activity and parameters were recorded in all the subjects.

Study Design

Study groups includes

Group-1: 30 Reproductive age women

Group-2: 30 Postmenopausal women

Inclusion Criteria:

Suitable subjects, who accept to take part in this research,

Subjects with no history of any chronic disorder,

Reproductive age women with a history of regular menstrual cycle.

Exclusion Criteria

The following subjects are excluded from the study:

Smokers, Alcoholics,Obese individuals those who are on exogenous hormone replacement therapy or lipid lowering drugs

Subjects with the following chronic disorders are also excluded:

- Cardiovascular disease and hypertension,

- Diabetes mellitus, •

- Hepatic, thyroid, renal, and gall bladder diseases

Measurement of biochemical parameters:

Venous blood samples (5 ml) were collected from 60 subjects after an overnight fast for determination serum lipid profile. The serum was separated within 2 hours of blood collection using a centrifuge at 1000 rpm for about 20 minutes at room temperature. Estimation of Total cholesterol (TC) ,Triglycerides(TG) and (High densitylipoprotein)HDL was carried out using enzymatic method. Low density lipoprotein (LDL), VLDL were also estimated. BMI was calculated (measured as weight in kilograms divided by square of height in meters). Lipid profile was compared in 2 groups. The data collected in this study was analyzed statistically by computing the descriptive statistics viz .mean, standard deviation, The 'P' value ≤ 0.05 was considered as statistically significant.

Results:

Table 1: Shows the mean, standard deviation, for age difference in 2 age groups.

Age	Reproductive age group (20-45 years) n=30	Post menopausal age group (46-60) n=30
Mean	33.24	54.33
Standard Deviation	6.90	2.27

Table 2: shows values of Lipid profile parameters in Reproductive age group and Post menopausal age group

Parameters	Post menopausal age group (46-60 years) n=30		Reproductive age group (20-45 years) n=30		P value
	Mean	SD	Mean	SD	
BMI	25.74	2.88	23.11	2.64	0.0005095
TC mg%	206.53	59.84	170.3	36.34	0.0063077
HDL mg%	43.13	6.49	55.33	41.27	0.1151860
LDL mg%	124.43	70.24	102.63	27.48	0.1188853
VLDL mg%	35.6	10.65	25.5	6.94	< 0.00001
TG mg%	162.76	68.01	129	33.98	0.0180973

In both groups from reproductive to post menopausal women BMI, TC, LDL, VLDL, TG, is gradually increased. HDL is gradually decreased from reproductive to post menopausal women, it is statistically significant.

Discussion

In the present study there was a significant difference in BMI, TC, LDL, HDL, VLDL ,TG, Diet, physical activity with significant p value of <0.05 Estrogen has a beneficial effect on lipid metabolism .Estrogen reduces the degradation of HDL by inhibiting the enzymatic action of lipoprotein lipase. So in the presence of estrogen there will be more amount of HDL in the reproductive women. Ovaries are the only source for estrogen in the women and these ovaries become inactivated and the source of estrogen is reduced in the postmenopausal women. So the postmenopausal women have more degradation of HDL when compare to reproductive women so the HDL levels are decreased in the post menopausal women. Post menopausal women had higher had higher TC, and lower HDL levels. **Goswami K and Bandyopadhyay A** showed that HDL cholesterol was significantly decreased in post menopausal women and significant rise in TC and LDL –cholesterol[12]. **Gandhi BM** showed Triglycerides in plasma increased with age [13]. **Bonithon-kopp** concluded that total cholesterol and LDL cholesterol significantly increased in postmenopausal women[14]. **Nerbrand et al, smiti nanda et al** suggested that loss of endogenous sex steroids contribute substantially to increased atherogenic lipid profile[15]. **Bhagya et al** concluded that total cholesterol increases significantly with age and the significant rise in LDL is mainly due to hormonal levels in post menopausal women[16]. Our study group being otherwise normal subjects .Assessing the presence of major CVD risk factors in women of particular importance, since it would allow us to promptly identify persons at high risk for development of clinical CVD later in life. We concluded the presence of normal lipid profiles and Cardio protective HDL is normally higher in prepubertal females. Lower levels of HDL increases CVD risk. This can be attributed mainly to sedentary life style, stress and dietary habits this is seen in post menopausal women.

Conclusion:

From our study it is evident that the mean values of total Cholesterol, LDL were higher and HDL was lower in menopausal women due to estrogen deficiency when compared with reproductive age group women. Dyslipidemia occurs due to multifactorial reasons like physical activity, life style, diet, smoking, alcohol consumption, ethnicity and genetic makeup. So further extensive studies with importance to the duration following menopause need to be done to understand the underlying mechanism

Introduction:

Menopause is the cessation of menstrual cycle in women. It represents a transitional phase in the natural biological woman's age, a natural event that marks the end of the reproductive years of women in terms of the menstrual cycle permanently stopped and the resulting stop ovarian function in females [1]. Most of the women at this stage suffer from a variety of symptoms due to hormonal changes and these symptoms are possible to be severe and frequent, some women have more severe symptoms and others do not suffer from any symptoms at all [2]. Menopause is an oestrogen deficient state characterised by permanent amenorrhoea lasting for a period of 1 year due to the cessation of ovarian functions.[3] There is considerable variation in the level of estrogen in postmenopausal women occurs during the early postmenopausal years because of continued secretion of estradiol from the ovary and conversion of androstenedione to estrone in fat tissue.[4] In young women, where oestrogen production is high, serum lipids are normal but after menopause, lipid levels are increased resulting in increased incidence of coronary heart diseases. This shows the possible relationship among oestrogen, normal lipid profile and atherosclerosis and the relative immunity to coronary artery diseases (CAD).[5] Natural menopause confers a 3 fold increase in CAD risk and postmenopausal women account for > 30% of the female population at risk for CAD in India.[6,7]. Circulating Serum Cholesterol, Low Cholesterol (LDL-C) and Serum Triglycerides are major

risk factors of this disease. The incidence of cardiovascular disease after menopause may partly be due to changes in the plasma lipid level that occurs following menopause.(8,9) The modification of profile may be important both in the prevention and control of coronary heart disease(10) . Estrogen leads to the increased risk of cardiovascular diseases after menopause, as evidenced by reduction in the cardiovascular diseases after hormone replacement therapy. Estrogen replacement therapy, through an effect on the blood vessel wall and on serum lipids, also appears to stabilize existing atherosclerotic plaques. Antithrombotic therapy, exercise and smoking cessation also contribute to reduced risk of cardiovascular disease in older women(11). In order to contribute to the better understanding of lipid profile status in postmenopausal women, the present study was conducted to estimate the serum levels of total cholesterol (TC), triglyceride (TG),high density lipoprotein cholesterol (HDL-C), low density lipoprotein cholesterol (LDL-C), very low density lipoprotein cholesterol (VLDL-C), and atherogenic index and compare it with premenopausal women.

Material and Methods:

The present study was undertaken to know serum lipid profile changes in reproductive and postmenopausal women. Healthy subjects with no evidence of metabolic or endocrinal abnormalities, hypertension or coronary heart disease were selected randomly for reproductive and post menopausal age group consisting of 30 subjects in each group .Total 60 Subjects of age group 20-45years (reproductive), 46-60 years (postmenopausal) female volunteered for our study. During the study period, anthropometric, biochemical dietary intake and physical activity and parameters were recorded in all the subjects.

Study Design

Study groups includes

Group-1: 30 Reproductive age women

Group-2: 30 Postmenopausal women

Inclusion Criteria:

Suitable subjects, who accept to take part in this research,

Subjects with no history of any chronic disorder,

Reproductive age women with a history of regular menstrual cycle.

Exclusion Criteria

The following subjects are excluded from the study:

Smokers, Alcoholics,Obese individuals those who are on exogenous hormone replacement therapy or lipid lowering drugs

Subjects with the following chronic disorders are also excluded:

- Cardiovascular disease and hypertension,

- Diabetes mellitus, •

- Hepatic, thyroid, renal, and gall bladder diseases

Measurement of biochemical parameters:

Venous blood samples (5 ml) were collected from 60 subjects after an overnight fast for determination serum lipid profile. The serum was separated within 2 hours of blood collection using a centrifuge at 1000 rpm for about 20 minutes at room temperature. Estimation of Total cholesterol (TC) ,Triglycerides(TG) and (High densitylipoprotein)HDL was carried out using enzymatic method. Low density lipoprotein (LDL), VLDL were also estimated. BMI was calculated (measured as weight in kilograms divided by square of height in meters). Lipid profile was compared in 2 groups. The data collected in this study was analyzed statistically by computing the descriptive statistics viz .mean, standard deviation, The 'P' value ≤ 0.05 was considered as statistically significant.

Results:

Table 1: Shows the mean, standard deviation, for age difference in 2 age groups.

Age	Reproductive age group (20-45 years) n=30	Post menopausal age group (46-60) n=30
Mean	33.24	54.33
Standard Deviation	6.90	2.27

Table 2: shows values of Lipid profile parameters in Reproductive age group and Post menopausal age group

Parameters	Post menopausal age group (46-60 years) n=30		Reproductive age group (20-45 years) n=30		P value
	Mean	SD	Mean	SD	
BMI	25.74	2.88	23.11	2.64	0.0005095
TC mg%	206.53	59.84	170.3	36.34	0.0063077
HDL mg%	43.13	6.49	55.33	41.27	0.1151860
LDL mg%	124.43	70.24	102.63	27.48	0.1188853
VLDL mg%	35.6	10.65	25.5	6.94	< 0.00001
TG mg%	162.76	68.01	129	33.98	0.0180973

In both groups from reproductive to post menopausal women BMI, TC, LDL, VLDL, TG, is gradually increased. HDL is gradually decreased from reproductive to post menopausal women, it is statistically significant.

Discussion

In the present study there was a significant difference in BMI, TC, LDL, HDL, VLDL ,TG, Diet, physical activity with significant p value of <0.05 Estrogen has a beneficial effect on lipid metabolism .Estrogen reduces the degradation of HDL by inhibiting the enzymatic action of lipoprotein lipase. So in the presence of estrogen there will be more amount of HDL in the reproductive women. Ovaries are the only source for estrogen in the women and these ovaries become inactivated and the source of estrogen is reduced in the postmenopausal women. So the postmenopausal women have more degradation of HDL when compare to reproductive women so the HDL levels are decreased in the post menopausal women. Post menopausal women had higher had higher TC, and lower HDL levels. **Goswami K and Bandyopadhyay A** showed that HDL cholesterol was significantly decreased in post menopausal women and significant rise in TC and LDL –cholesterol[12]. **Gandhi BM** showed Triglycerides in plasma increased with age [13]. **Bonithon-kopp** concluded that total cholesterol and LDL cholesterol significantly increased in postmenopausal women[14]. **Nerbrand et al, smiti nanda et al** suggested that loss of endogenous sex steroids contribute substantially to increased atherogenic lipid profile[15]. **Bhagya et al** concluded that total cholesterol increases significantly with age and the significant rise in LDL is mainly due to hormonal levels in post menopausal women[16]. Our study group being otherwise normal subjects .Assessing the presence of major CVD risk factors in women of particular importance, since it would allow us to promptly identify persons at high risk for development of clinical CVD later in life. We concluded the presence of normal lipid profiles and Cardio protective HDL is normally higher in prepubertal females. Lower levels of HDL increases CVD risk. This can be attributed mainly to sedentary life style, stress and dietary habits this is seen in post menopausal women.

Conclusion:

From our study it is evident that the mean values of total Cholesterol, LDL were higher and HDL was lower in menopausal women due to estrogen deficiency when compared with reproductive age group women. Dyslipidemia occurs due to multifactorial reasons like physical activity, life style, diet, smoking, alcohol consumption, ethnicity and genetic makeup. So further extensive studies with importance to the duration following menopause need to be done to understand the underlying mechanism

Abstract

Context: Alcohol consumption has been steadily increasing all over world, especially in India. Alcohol can cause physical, mental and social effects which is determined by quantity and pattern of alcohol drinking.

Aim: Present study was conducted to observe alterations in the biochemical and haematological parameters in heavy alcohol consumers.

Subjects and Method: 40 young males of 20-40 years age with history of daily alcohol consumption for past one to five years duration were included in study .Estimation of the biochemical and haematological parameters were carried out in study and control subjects**.**

Statistical Analysis: Analysis of the haematological and biochemical parameters data of the study subjects and controls was done by using student t test

Results: Lipid profile parameters were not altered in study subjects .Liver enzymes AST and ALT were significantly elevated in alcoholic subjects. Hemoglobin and platelets was lower in alcoholic subjects. Mean corpuscular volume was significantly higher in alcoholics.

Conclusion: These alterations of liver enzymes and haematological parameters in alcoholics can be used as early indicator of alcohol abuse and person can be motivated to stop alcohol consumption.

Key words: Alcoholics, Lipid profile, Liver enzymes, Hemoglobin

Introduction

Alcohol is not often thought as a drug largely because its use is common for both religious and social purposes in most parts of world. However , it is a drug and of all the drugs , alcohol is the only drug whose self induced intoxication is socially acceptable. Compulsive drinking in excess has become modern society's one of the most serious problems [1] . Alcohol has been widely consumed through ages because of its perceived benefits as a social lubricant and for relaxation , mood alteration and sensory pleasure . But long term consumption of large amount is harmful leading to addiction and fatal or non fatal injuries . Alcoholism is a worldwide social and medical problem . Over the past 30-40 years , alcohol consumption has increased in quantity and frequency [2] . The age at which people start drinking has also declined. Consumption of alcohol in young people has created concern as alcoholism may run a greater risk of alcoholic problems in later life [3] .All organs can be damaged due to direct effects of alcohol, especially the digestive and nervous systems . At the level of

digestive system , alcohol causes gastrointestinal problems , cirrhosis of liver , pancreatitis and cancer of mouth , pharynx and oesophagus . At level of nervous system it causes problems with reflexes , vision , equilibrium of the body , lesions of nerves [4] . Alcohol has numerous adverse effects on various types of blood cells and their functions [5]. Other effects include loss of appetite, vitamin deficiency , infection , sexual impotence and menstrual irregularities. The diagnosis occurs when the adverse effects are already obvious and recognizable[6]. Effective and low cost methods are now available for identification and treatment of alcohol addiction at an early stage . They include various haematological and biochemical parameters. Some of the commonly studies parameters are Aspartate amino transferase (AST), Alanine amino transferase (ALT) , Alkaline Phosphatase, and haemoglobin (Hb%) , Mean corpuscular volume (MCV) , Mean corpuscular Haemoglobin (MCH) . Combination of one or more of these markers has been reported to give better sensitivity and diagnostic accuracy characterizing the early events leading to alcoholic disease at later stage. Earlier studies have shown the once the alcohol consumption is stopped at earlier stage, the alteration are reversed, thus altering the pathway of morbidity and mortality and ensure a disease free life to the individual.

The present study was done to identify the alteration in serum lipid profile, liver enzymes (AST, ALT) and haematological parameters like haemoglobin (Hb%) Mean corpuscular volume (MCV) , Mean corpuscular Haemoglobin (MCH) , platelet counts in asymptomatic young alcoholic individuals of 20-40 years age group, which were considered as a heavy drinkers with history of consumption of alcohol for one to five years.

Material and methods:

This case control study was conducted in November 2019 to February 2020 . The study was done by obtaining blood and serum samples from study and control subjects . The samples were drawn in morning under aseptic precautions after over night fast . The study group consisted of 40 subjects and 40 control subjects . They were selected on the basis of following inclusion and exclusion criteria.

Inclusion criteria:

Male subjects aged 20-40 years with history of heavy alcohol consumption for duration of one to five years .

Exclusion criteria :

Person with following disorders were not included in study.

- Hypertension
- Diabetes mellitus
- Malignant condition
- Cardiovascular and respiratory disorders
- Individual on medication
- Smokers

Collection of blood samples , which is invasive procedure and need overnight fasting was explained to the subjects in detail. Subjects unconditionally gave consent to participate in study. The study complied with the Declaration of Helsinki and protocol was approved by the institution review board.

Method of collection of data.

- A questionnaire was given to the subjects and controls to elicit the details of alcohol consumption , history of past or present illness [7] .

- The average number of alcohol drinks consumed per mouth was asked .Daily consumption of six or more drinks (> 90 ml daily) was defined as heavy drinker [8] .
- Height and weight was recorded . Body mass index was calculated.
- Vital parameters like pulse rate , Blood pressure was recorded .Detail examination of cardiovascular , Respiratory system , Abdomen and Central nervous system was done.
- Under aseptic precautions 4 ml of blood was drawn from anterior cubital vein .2ml was taken in EDTA bulb for estimation of Haematological parameters and 2 ml was taken in a plain bulb for estimation of lipid profile and liver enzymes in blood .
- Serum lipid profile and liver enzymes were estimated by using Biochemistry Analyzer.
- Haematological parameters were measured by using Automated hematology Analyzer.
- Following parameters were studied .

1) Lipid profile - Total cholesterol (TC) ,High density lipoprotein cholesterol (HDL-C) ,low density lipoprotein cholesterol (LDL-C) , Very low density lipoprotein cholesterol (VLDL-C), and Triglycerides TL.
2) Liver enzymes - Aspartate amino transferase (AST) , Alanine amino transferase (ALT) , Alkaline Phosphatase .
3) Haematological parameters like haemoglobin (Hb %) , Mean corpuscular volume (MCV) , Mean corpuscular Haemoglobin (MCH) , platelet counts

Statistical Analysis :

Analysis of the haematological and biochemical parameters data of the study subjects and controls was done by using student t test [9,10] . p value was calculated , $p < 0.05$ was considered significant and $p < 0.01$ was considered highly significant , > 0.05 was considered not significant .

Results :

The results obtained were expressed as Mean ± Standard deviation . p value was calculated

Anthropometric data

The table 1 shows anthropometric data of the study subjects and controls . There was no significant difference in Age , Weight , Height , BMI between study and control groups.

Table 1 : Anthropometric data of control and study subjects .

Anthropometric Parameters	Control subjects Mean ± SD (n = 40)	Study subjects Mean ± SD n = 40	P value	Significance
Age (Years)	30.8 ± 2.8	31.48 ± 3.22	> 0.05	Not Significant
Weight (Kg)	60 ± 7.23	63.36 ± 4.24	> 0.05	Not Significant
Height (Cm)	165.3 ± 7.2	163.4 ± 5.82	> 0.05	Not Significant
BMI (Kg/ m^2)	22.82 ± 2.54	23.24 ± 2.24	> 0.05	Not Significant

Vital data

Resting pulse rate :

The Mean ± SD of pulse rate at rest in control was 76.24 ± 3.26 beats / minute and in study subject was 72 ± 4.32 beats / minute .There was no significant difference in the resting pulse rate between the two groups.

Blood Pressure :

The Mean ± SD systolic blood pressure at rest in controls was 122.24 ± 4.26 mm Hg and 124.42 ± 6.18 mm Hg in study subjects .

The Mean ± SD diastolic blood pressure was 78.62 ± 4.24 mm Hg in control and 76.34 ±3.82 mm Hg in study subjects.
There was no significant difference in Blood Pressure between study and control group.

Lipid Profile :

The lipid profile data of study and controls are shown in Table 2.

Table 2: Lipid profile data of control and study subjects .

Parameters of Lipid Profile (mg/dl)	Control subjects Mean ± SD (n = 40)	Study subjects Mean ± SD (n = 40)	P value	Significance
Total cholesterol	210 ± 36.24	218.18 ± 32.46	> 0.05	Not Significant
HDL-cholesterol	42.46 ± 6.48	40.24 ± 8.21	> 0.05	Not Significant
LDL-cholesterol	140.18 ± 32.78	138.24 ± 30.68	> 0.05	Not Significant
VLDL-cholesterol	26.82 ± 10.26	27.76 ± 11.34	> 0.05	Not Significant
Triglycerides	148.72 ± 48.26	150.36 ± 44.34	> 0.05	Not Significant

There was no significant difference between the serum lipid profile parameters between study and control subjects.

Liver enzymes :

The data of liver enzymes of study and controls are shown in table 3.

Table 3: Liver Enzymes data of control and study subjects

Liver enzymes (IU/L)	Control subjects Mean ± SD (n = 40)	Study subjects Mean ± SD (n = 40)	P value	Significance
AST	21.38 ± 6.72	34.42 ± 7.26	<0.01	Highly Significant
ALT	16.84 ± 8.03	25.76 ± 9.34	<0.05	Significant
Alkaline Phosphatase	62.76 ± 11.42	60.82 ± 9.34	>0.05	Not Significant

AST levels were more in alcoholic subjects as compared to control subjects and this difference was statistically highly significant .
ALT levels were significantly higher in alcoholic subjects as compared to control group subjects.
There was no significant difference in alkaline phosphatase levels between the two groups.

Haematological parameters :

Table 4: Haematological parameters of study and controls .

Haematological parameters	Control subjects Mean ± SD (n = 40)	Study subjects Mean ± SD (n = 40)	P value	Significance
Haemoglobin (gm/ dl)	13.64 ± 1.24	11.34 ± 1.05	<0.05	Significant
Mean corpuscular volume(fL)	84.76 ± 5.37	92.84 ± 6.24	<0.01	Highly Significant
Mean corpuscular aemoglobin(pg)	31.86 ± 1.24	32.241.18	>0.05	Not Significant
Platelet count (lac /mm^3)	2.75 ± 0.67	2.01 ± 0.48	<0.01	Highly Significant

Haemoglobin was lower in study subjects .There was significant difference in haemoglobin levels in study and control group subjects .The Mean corpuscular volume of the study subjects was significantly higher as compared to controls. There was no significant difference in Mean corpuscular Haemoglobin values between two groups. Platelet count was lower in the study subjects as compared to control subjects and this difference was highly significant.

Discussion :

This study was conducted to find the effects of alcohol abuse in young adults of 20-40 years age group with history of heavy consumption of alcohol for duration of one to five years .The effects of alcohol intake on serum lipids and lipoprotein depends on the dose and mode of alcohol intake , individual susceptibility , genetic variables and dietary factors .In heavy drinkers the synthesis of VLDL is stimulated .Even short term use of alcohol stimulate lipoprotein lipase activity in adipose tissue and consequently the concentration of VLDL in plasma stays normal or is even subnormal . There is increased transport rate of VLDL particles as a result of high lipoprotein lipase activity results in upregulation of HDL receptors [11].

In our study , lipid profile parameters like Total cholesterol , HDL cholesterol LDL cholesterol and triglycerides were studied .We observed that there was no significant alteration in the lipid profile parameters between control and study subjects. This findings correlates with the previous study done by T. Oduaola et al in which there was no association between alcohol intake with total cholesterol levels [12]. Similar observation were also found in a study conducted by Marita Passilta et al in which there was no difference in HDL-C and LDL-C concentration between controls and in those with highest alcohol intake [13]. However , Vaswani . M et al in their study found values of Total cholesterol , HDL-C , VLDL-C , Triglycerides except LDL-C were higher in alcohol dependents as compared to non dependent subjects . Similarly study by John .B Whitfield et al , showed that the triglycerides levels were increased with increasing alcohol intake . Studies by J.B Ruidavets et al and Hans Hoffmeister et al , found that blood levels of HDL- C increased with increasing alcohol intake [14,15] . The above studies were conducted in people with history of longer duration of alcohol consumption of greater than 5 years , which may be reason for the alteration in lipid profile in these subjects . Our results showed no alteration in lipid profile as our subjects were exposed to shorter duration of one to five years . In our study we studied the liver enzymes like SGOT , SGPT , and alkaline phosphatase .We observed that the liver enzymes SGOT , SGPT were significantly higher in study subjects as compared to controls . Alkaline phosphatase did not alter in both groups. Osaretin Albert Taiwo Ebuehi et all in a study found the activities of SGOT , SGPT Alkaline phosphatase of heavy drinkers were higher as compared to moderate drinkers and non drinkers [16] .An association between liver disease and heavy alcohol consumption was recognised more than 200 years ago [17] . The liver is particularly susceptible to alcohol related injuries .Since liver is the major site of alcohol metabolism .Alcohol is broken down in liver and free radicals are generated .Liver injury is caused by direct toxicity of free radicals [18]. When hepatocytes are damaged , they leak enzymes in to blood .Hence level of liver enzymes in plasma is important indicator of liver dysfunction .

Various haematological parameters like Haemoglobin content , Mean corpuscular volume , Mean corpuscular haemoglobin and Platelets were studied in our study. Haemoglobin was lower in alcoholic subjects as compared to controls subjects and this difference was statistically significant. Anemia was found in a study conducted by Subir Kumar Das et al , Latvala J et al and Louis.W Sullivan et al [19,20,21] . A number of clinical observation in man have suggested that alcohol may act as a haematological toxin in body. In our study MCV was higher in study subjects as compared to controls and this was statistically highly

significant. Platelets count was lower in study subjects as compared to controls and this difference was statistically highly significant. A study conducted by John Lindenbaum et al , showed a marked decrease in platelet count in alcoholics [22]. David Savage et al found an increase of MCV and lower platelet counts much more commonly associated with heavy alcoholic intake [23] .

The adverse effects of alcohol on Haemopoietic system are both direct and indirect . Direct effect of alcohol consumption include toxic effects on bone marrow and blood cell precursors. The indirect effect include nutritional deficiencies like folic acid and other vitamin resulting in macrocyte of red blood cells .Alcohol intake can interfere with a late stage of platelet production by suppressing the maturing megakaryocytes . Alcohol also shorts the life span of existing platelets .

Conclusion :

The present study concludes that consumption of alcohol for duration of one to five years may not alter the levels of lipid parameters in body .Liver enzymes were increased in heavy drinkers as compared to non alcoholics . Anaemia is commonly observed in alcoholics. There alteration can be considered as early indicater of alcoholism . These changes are found to be reversible once alcohol consumption is stopped as observed by many researchers .Therefore awareness should be created among public regarding major health problem associated with alcohol intake .This will help to lesser the damage and better recovery of alcoholic individuals .

Hyperuricaemia – A Potential Indicator to Diagnose the Risk of Essential Hypertension

CHANCHAL SHRIVASTAV[1], MANJINDER KAUR[2], M.L. SUHALKA[3], SUMAN SHARMA[4], ABHIJIT BASU[5]

ABSTRACT

Introduction: Hypertension has turned out to be the major cause of morbidity among the life style diseases. Studies in human and animal models have documented an independent association of hyperuricaemia with early hypertension. Hyperuricaemia is a modifiable and treatable risk factor, which might reduce the incidence of Essential Hypertension (EHT).

Aim: Hence, the present study was designed to find out the association between hyperuricaemia and EHT in the population of Southern Rajasthan as there is a dearth of literature on Indian scenario especially in Rajasthan.

Materials and Methods: A cross-sectional, case control study was carried out in the Department of Physiology among 125 subjects; aged 20-50 years of both sexes, which were chosen randomly from Medicine OPD and healthy volunteers. The subjects were broadly divided into two groups (A & B); group A comprised of newly diagnosed cases of EHT (n=75) and group B had healthy normotensive controls (n=50). S. Uric Acid (SUA), Serum creatinine and fasting blood glucose levels were estimated by using the respective kit methods on semi auto-analyser in both groups. S. creatinine and fasting blood glucose levels were estimated to exclude renal disorder and diabetes mellitus respectively. The data was analysed by student t-test, chi-square test and Odds Ratio.

Results: The mean SUA level in group A was significantly higher than group B (6.56 ± 0.76, 4.91 ± 0.97 mg/dl, $p<0.001$ respectively). 37.33% of patients had hyperuricaemia in group A as compared to 14% in group B ($p<0.01$, OR=3.66) indicating that a hyperuricaemic individual has 3.66 times more risk of developing EHT as compared to the one with lower value of SUA.

Conclusion: The mean SUA level and the frequency of hyperuricaemia was significantly higher in newly diagnosed cases of EHT as compared to healthy controls. Hence, SUA could be useful as a potential indicator for early risk detection of development of EHT.

Keywords: Primary hypertension, Preclinical hyperuricaemia, Serum uric acid, Southern Rajasthan

INTRODUCTION

Hypertension has emerged as a major public health problem in developing as well as developed countries. It is very common among the population, affecting 1 in 3 adults worldwide [1] which translates to nearly one billion in absolute numbers in the year 2000 and this is expected to grow to more than 1.5 billion by 2025 [2]. Increasing prevalence of hypertension is a documented public health problem in India as it predisposes to cardiovascular diseases [3,4]. A recent study by Sachdev, among tribal population of Rajasthan has shown 16% to 30% prevalence of hypertension among different tribes [5]. In 1870, Frederick Mohamed was the first to note the association of Serum uric acid (SUA) and Essential Hypertension (EHT) [6] and a recent re-evaluation of the Framingham Heart Study data has also suggested that a higher SUA level is associated with increased risk of hypertension [7]. Further, studies have even shown that hyperuricaemia is more commonly associated with primary EHT than in secondary hypertension, at least in adolescents [8]. Traditional modifiable risk factors have been extensively evaluated but there is a pressing need to identify additional treatable risk factors that are easily measured and highly prevalent in general population. Hyperuricaemia could be such potentially modifiable & treatable risk factor, which might reduce the incidence of EHT.

AIM

Hence, the present study was designed to establish the association between the SUA and risk of development of EHT in the population of Southern Rajasthan as there is dearth of literature for Indian scenarios especially in Rajasthan.

MATERIALS AND METHODS

The present study is a part of a bigger project carried out in the Department of Physiology of a tertiary care hospital. This cross-sectional, case control study included 125 subjects, chosen randomly from Medicine OPD and healthy volunteers like clinical and nonclinical staff of a hospital and individuals comings to hospital for health checkup during August 2013 to July 2014.

On the basis of a pilot study in our hospital, we calculated the incidence of new cases of hypertension to be 35%. We also found out the percentage of healthy controls, after meeting all the inclusion and exclusion criteria, to be around 22%. The sample obtained, was proportionally divided into cases and controls in the ratio of approximately 3:2.

All the age matched (20-50 years) and sex matched subjects were broadly divided into two groups (A&B); group A comprised of newly diagnosed cases of EHT (n=75) whereas group B had healthy normotensive controls (n=50). The subjects with gout, diabetes mellitus, gestational hypertension and/or secondary hypertension caused by renal disorders, metabolic disorders, fluid volume disturbances, endocrinal disorders etc. were excluded from both the groups. Smokers, alcohol consumers and patient using medication for hypertension were also excluded from both the groups.

After obtaining the ethical clearance from the institutional ethical committee, the data from both the groups were collected in a detailed proforma along with requisite physical examination. The biochemical parameters; SUA, Serum creatinine and fasting blood glucose levels, were estimated in both groups, for which 3 ml of blood was drawn after an overnight fast (12 h) by venous puncture. After clotting of blood, serum was separated by centrifugation at 3000 rpm for 10 minutes and used for biochemical analysis. The SUA level was measured on semi auto-analyser by Modified Trinder method [9]. Serum creatinine and fasting blood glucose levels, were estimated by Jaffe's Method [10] and enzymatic method, using Glucose Oxidase (GOD) and Peroxidase [11] respectively.

Serum creatinine and fasting blood glucose levels, were estimated to exclude renal disorder and diabetes mellitus respectively.

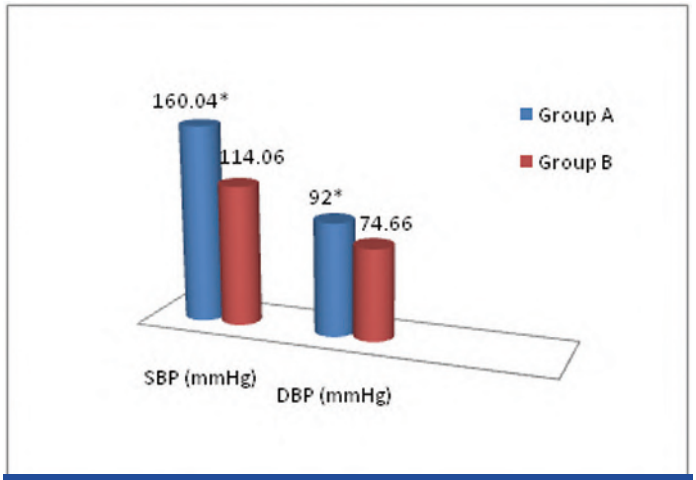
STATISTICAL ANALYSIS

The data was analysed by using Statistical Package for the Social Sciences (SPSS) Version 16.0. Association between EHT and hyperuricaemia was tested by Chi-square test and Odds ratio. Comparison of mean SUA level between group A and group B was tested by Student t-test.

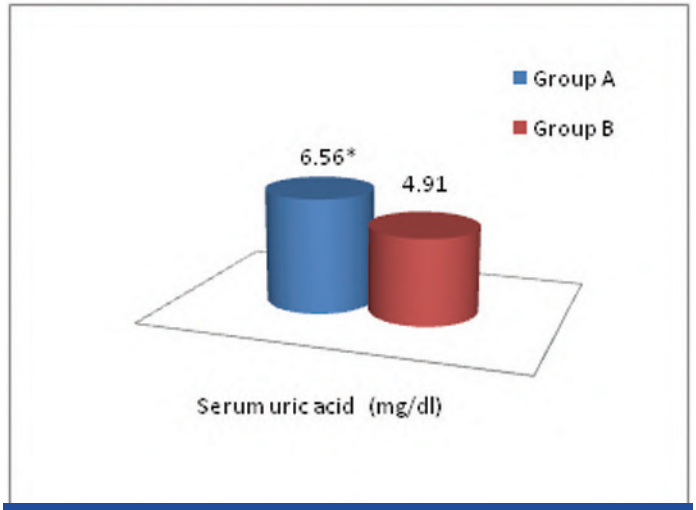
RESULTS

The mean age of group A and B were 40.25 ± 7.71 and 37.46 ± 8.09 years respectively (p<0.001). The mean systolic BP was 160.04 ± 16.77 mmHg and 114.06 ± 5.79 mmHg and the mean diastolic BP was 92.0 ± 10.15 mmHg and 74.66 ± 6.23 mmHg in group A and B respectively. The difference in mean systolic and diastolic BP was statistically significant (p<0.0001) between the two groups [Table/Fig-1].

In addition, we found that the mean SUA level was 6.56 ± 0.76 mg/dl and 4.91 ± 0.97 mg/dl in group A & B respectively, which was significantly higher in group A as compared to group B (p<0.001) [Table/Fig-2]. [Table/Fig-3] shows distribution of the study subjects according to hyperuricaemia in group A and group B.



[Table/Fig-1]: Mean systolic & diastolic blood pressure in both the groups.
* p<0.0001



[Table/Fig-2]: Comparison of SUA level between group A and B.
* p<0.001

Particulars	Total no. of subject	Subject with Hyperuricaemia	Percentage	Odds Ratio	p-value
Group A	75	28	37.33%	3.66	<0.01
Group B	50	7	14%		

[Table/Fig-3]: Distribution of the study subjects according to hyperuricaemia in group A and group B.
Odds Ratio (OR) = 3.66, p-value <0.01, p value reached from Chi-square test

Hyperuricaemia is defined as plasma uric acid level greater than 6.8 mg/dl at physiological temperature (37°C) and neutral pH [12].

DISCUSSION

As we know that a number of factors could affect blood pressure but they cannot completely explain the cause of EHT, which hints towards some unidentified risk factors associated with it. Since 1870, high SUA, a kind of purine metabolite, has been linked with EHT but of late it has just become diagnostic indicator of gout and renal functions, losing its significance in the pathogenesis of hypertension, cardiovascular and cerebrovascular diseases. From past centuries, a large number of epidemiological and clinical trials [7,8,13-15] have confirmed that the increased level of SUA is closely related to hypertension and other cardiovascular and cerebrovascular diseases but the lost significance of this indicator has led to surgence of the present study.

This study reflects the preclinical hyperuricaemia, as a potential risk factor for the development of EHT. An increasing trend was observed in mean serum uric acid level from control to hypertensive cases (p<0.001). These results were in concordance with several other studies which have also quoted significant increase in SUA level in essential hypertensive cases [16-19].

Further, the number of individuals with hyperuricaemia were significantly higher in group A than group B. This finding is in concurrence with other studies, which also reported 30.6% (OR= 2.13, p<0.05) and 28.8 % (OR=2.55, p<0.001) cases had hyperuricaemia with EHT respectively [16,17]. These results indicate a definite association between hyperuricaemia and EHT.

Hence, preclinical hyperuricaemia is a predictive tool for early detection of risk of development of hypertension. Several mechanisms have been suggested on the role of hyperuricaemia in the induction of systemic hypertension. Elevated SUA level lowers the endothelial nitric oxide level, by reducing nitric oxide synthase in the macula densa of the kidney with activation of renin-angiotensin system and mediates renal vasoconstriction that leads to uric acid mediated hypertension [13,20]. Persistent renal vasoconstriction may contribute to arteriosclerosis and the development of salt sensitive hypertension, even if hyperuricaemia is corrected [21]. This mechanism was demonstrated in animal studies by Mazzali et al., in which rats developed high blood pressure in about 3 to 5 weeks after raised SUA level; was induced by the administration of oxonic acid which is an inhibitor of uricase [22]. Animal and human studies have repeatedly shown an independent association of hyperuricaemia with early hypertension [8,14,19] and hypertension is a well documented preliminary risk factor for the development of coronary artery disease (CAD). In one small study, the use of allopurinol, a xanthine oxidase (XO) inhibitor, resulted in reduction of BP in adolescents with newly diagnosed hypertension with hyperuricaemia [23]. In another small study, UA lowering therapy with either allopurinol or probenecid, a uricosuric agent, significantly reduced BP in prehypertensive obese adolescent with hyperuricaemia irrespective of UA lowering mechanism [15]. Although, several international authorities such as the Joint National Committee on prevention, detection, evaluation and treatment of high blood pressure and the American Heart Association have not recognized elevated SUA as an important risk factor for CAD, but studies in humans with asymptomatic hyperuricaemia have demonstrated its association with EHT, CAD, obesity, kidney disease and metabolic syndrome [13].

The preclinical asymptomatic rise in SUA, though largely ignored, is a potential risk indicator for EHT. Hence, this study recommends the screening of SUA to detect the risk of developing EHT in future.

LIMITATIONS

First, this was a cross-sectional study and so did not permit us to make any inference on the causal relationship between uric acid and hypertension. Secondly, the limited sample size also limited the power of the analysis. A further study designed as a prospective randomized follow up study with a larger sample size would be required to substantiate the results of the present study.

CONCLUSION

The mean SUA levels and the frequency of hyperuricaemia were significantly higher in newly diagnosed cases of EHT as compared to normotensive healthy controls. Though the SUA level was within the normal reference range, it was significantly elevated in newly diagnosed cases of EHT. In clinical practice, measurement of SUA level may help to detect the risk of development of EHT. Moreover, further studies can be carried out to evaluate the SUA as a modifiable risk factor, to lower the incidence of EHT per se.

ACKNOWLEDGMENT

I sincerely acknowledge the financial and mental support of Mr. Vinod Shrivastav during the study.

Significance of Dietary Pattern in Oxidative Stress among Newly Diagnosed Essential Hypertension

Chanchal Shrivastav[1], Suman Sharma[2], G. Indra Kumar[3]

[1]Associate Professor, Department of Physiology, Ananta Institute of Medical Sciences and Research Center, Rajsamand, Rajasthan, [2]Associate Professor, Department of Physiology, Geetanjali Medical College and Hospital, Udaipur, Rajasthan, [3]Assistant Professor, Department of Physiology, Ananta Institute of Medical Sciences and Research Center, Rajsamand, Rajasthan

Abstract

Background: Hypertension is a significant global public health problem and it is associated with increased oxidative stress. Oxidative stress is disequilibrium between tissue oxidants (free radicals or reactive oxygen species ROS) and antioxidants and may be an integrative mechanism in the progress of cardiovascular diseases (CVD).

Aims & Objectives: To study the impact of dietary pattern on oxidative stress markers in newly diagnosed essential hypertension.

Material and Method: The study was conducted on 75 cases of essential hypertension (HT), 75 prehypertensives (preHT) and 50 control subjects for 15 months. After screening, serum uric acid (SUA) and serum malondialdehyde (S.MDA) level were investigated in both vegetarians (V) and nonvegetarians (NV) in all groups.

Findings: The difference in mean ± SD of SUA and S. MDA level between control, preHT and HT group were found to be highly significant ($p<0.0001$). SUA and S. MDA level was higher in NV as compared to vegetarians in all groups but significant results were found in case of SUA ($p<0.001$).

Conclusion: Long-term vegetarians have improved antioxidant status and coronary heart disease risk profile than do apparently healthy omnivores.

Keywords: *Hypertension, prehypertension, oxidative stress, serum uric acid, serum malondialdehyde, vegetarians, nonvegetarians, systolic blood pressure (SBP), diastolic blood pressure (DBP) .*

Introduction

Hypertension is one of the most important public health challenge world-wide because of its high incidence and associated risks of cardiovascular disease for instance stroke, myocardial infarction and heart failure. Although it has frequently been indicated that the causes of essential hypertension are not known, this is only partially true. Essential hypertension is a heterogeneous disorder, with different patients having different causal factors that lead to high blood pressure. Vascular oxidative stress has been shown in genetic and experimental models of hypertension.[1] In search for a causative factor for essential hypertension, uric acid and lipid peroxidation due to increased oxidative stress are considered.

Although serum uric acid is regarded to be an antioxidant within its normal physiological conditions, it might be accountable for production of free radicals directly or indirectly in hypertensive. Hyperuricaemia (plasma uric acid level more than 6.8 mg/dl at

physiological temperature (37°C) and neutral pH)[2] has been found to be associated with subsequent morbidity and mortality in the general population among patients with congestive heart failure, diabetics and hypertensive patients. Moreover, hyperuricaemia has also been linked to multiple proatherogenic processes, including increased oxidative stress. In recent years, oxidative stress due to ROS is implicated in the pathogenesis of ample variety of diseases like cancer, cataract, diabetes mellitus, rheumatoid arthritis, atherosclerosis, hypertension.[3] In addition the reasons for augmented rate of hypertension include life style changes, sugar rich diet, high fat processed foods and sedentary behavior.[4]

Rapid changes in diets and lifestyles that have took place with urbanization, industrialization and economic advancement have intensified over the past decade. Because of these changes, chronic diseases like hypertension are becoming increasingly significant cause of impairment and premature death.

Material & Method

A hospital based case control study was conducted among 200 subjects of age group between 20–50 years, irrespective of sex in the department of Physiology, Geetanjali medical college & hospital (GMCH), Udaipur.

Inclusion criteria: All the subjects were chosen randomly and following groups were made according to JNC7 criteria

Control group: 75 normotensive subjects

PreHT group: 75 cases of prehypertension

HT group: 75 cases of newly diagnosed cases of essential hypertension with SBP= 140-159 mmHg, DBP= 90-99 mmHg.

Exclusion criteria:

Patients with secondary hypertension, gout, diabetes mellitus, gestational hypertension, and patients taking antihypertensive, smokers and alcohol consumers were excluded from the study.

After obtaining ethical approval (Ref. No. GU/UCE/EC/2013/299 dated 15/05/2013), a written voluntary informed consent was obtained from all the subjects. Then all the subjects were screened as per the detailed history, routine physical examination and appropriate tests. After screening, blood sample (5 ml) was drawn in to a plain vial after an overnight fast (12 hrs) by antecubital venous puncture from all the subjects. Then serum was separated by a centrifugation at 3000rpm for 10 minutes. After that serum sample was used for following biochemical analysis.

Serum Uric Acid: By Modified Trinder Method.[5]

Serum Malondialdehyde (MDA): Thiobarbituric acid (TBA) assay method.[6]

Statistical Analysis: The data were analyzed by using Statistical Package for the Social Sciences (SPSS) Version 16.0. Difference between the groups was analyzed by Analysis of variance test (ANOVA). Diet wise comparison of oxidative stress parameters were tested by Student t-test with p value <0.05 is considered as statistically significant.

Findings

Table: 1 Characteristics of study population among different groups (Mean ±SD)

Variables	Control	Pre HT Group	HT Group	Anova P Value
Age (Yrs.)	37.46 ± **8.09**	35.84 ± **6.5**	40.25 ± 7.71	<0.001
Veg./ Nonveg.	68/32	51/49	40/60	-
SBP (mmHg)	114.06 ± **16.77**	134.00 ± **5.1**	160.04 ± **11.49**	<0.0001
DBP (mmHg)	74.66 ± **6.23**	86.45 ± **2.93**	92.00 ± **10.15**	<0.0001

The difference in mean ± SD of SBP & DBP between three groups were highly significant (p<0.0001).

Table: 2 Diet wise variation of SBP among different groups (Mean ± SD)

	Control			PreHT			HT		
Diet	**Mean**	**SD**	**N**	**Mean**	**SD**	**N**	**Mean**	**SD**	**N**
Non Veg	114.62 ± 6.37		16	134.38 ± 5.01		37	161.82 ± 12.52		45
Veg	112.88 ± 5.84		34	133.63 ± 5.24		38	157.37 ± 9.33		30
T value	0.92			0.63			1.76		
P value	NS			NS			NS		

Table: 3 Diet wise variation of DBP among different groups (Mean ± SD)

	Control			PreHT			HT		
Diet	**Mean**	**SD**	**N**	**Mean**	**SD**	**N**	**Mean**	**SD**	**N**
Nonveg	75.21 ± 6.75		16	87.27 ± 2.83		37	92.44 ± 11.17		45
Veg	73.50 ± 5.99		34	86.63 ± 3.05		38	91.33 ± 9.68		30
T value	0.87			0.94			0.46		
P value	NS			NS			NS		

The table no. 2 & 3 showed that mean ± SD value of both SBP and DBP were higher in NV as compared to V among all three groups but the results were not significant (p>0.05)

Table: 4 Comparison of SUA and S. MDA level among different groups (Mean ± SD)

Variables	Control	Pre HT Group	HT Group	Anova P Value
S. Uric acid (mg/dL)	4.91 ± 0.97	5.90 ± 0.97	6.56 ± 0.76	<0.0001
S. MDA (nmol/mL)	1.30 ± 0.20	1.63 ± 0.28	2.14 ± 0.42	<0.0001

The difference in mean ± SD of SUA and S. MDA level between control, preHT and HT group were found to be highly significant (p<0.0001).

Table: 5 Diet wise variation of SUA level among different groups (Mean ± SD)

Diet	**Control**			**Pre HT group**			**HT Group**		
	Mean	**SD**	**N**	**Mean**	**SD**	**N**	**Mean**	**SD**	**N**
Non veg	5.65 ± 0.77		16	6.55 ± 0.80		37	6.77 ± 0.59		45
Veg.	4.56 ± 0.69		34	5.24 ± 0.53		38	6.19 ± 0.56		30
T value	4.82			8.34			4.25		
P value	<0.0001			<0.0001			<0.001		

Mean ± SD of SUA was significantly higher in NV as compared to vegetarians in all groups (p<0.001).

Table: 6 Diet wise variation of S. MDA level among different groups (Mean ±SD)

Diet	Control			Pre HT group			HT Group		
	Mean	SD	N	Mean	SD	N	Mean	SD	N
Non veg	1.33 ± 0.19		16	1.68 ± 0.27		37	2.20 ± 0.43		45
Veg.	1.28 ± 0.21		34	1.57 ± 0.27		38	2.04 ± 0.39		30
T value	0.84			1.76			1.67		
P value	NS			NS			NS		

Mean ± SD of S.MDA level was higher in NV as compared to V among HT, preHT and control group but this difference was not statistically significant ($p>0.05$).

Discussion

There is a close relationship between the diet and chronic degenerative diseases such as obesity, hypercholesterolemia and hypertension. Our study showed that NV had higher mean SBP and DBP than V in HT, preHT and control group but the results were not significant ($p>0.05$). Our results were similar to the study of Nande PJ et al.[7] but they found significant results in case of DBP ($0.01<p<0.05$). These findings are steady with the results of the DASH (Dietary Approaches to Stopping Hypertension) trial, that a dietary pattern plenteous in fruits, vegetables, low fat dairy products and with abbreviated total and saturated fat can be efficient in the suppression of hypertension.[8] Diet represents a significant role in the primary suppression of hypertension. It is a conception that the non vegetarian diet comprises cholesterol and saturated fatty acids and these are the root cause of problems like coronary heart diseases and hypertension. Vegetarian diets are normally ample in carbohydrates, n-6 fatty acids and dietary fiber and are more helpful in preventing, treating or reversing heart disease. Lifestyle adjustments in diet are playing important role in determining the outcome for people with hypertension.[9]

In the present study serum uric acid level was found to be significantly high in NV as compared to vegetarians among HT, preHT and control group ($p<0.001$). Choi HK et al.[10] also noticed that SUA level enhanced with increasing total meat or sea food intake and diminished with increasing dairy intake. Similarly Schmidt JA et al.[11] found that vagan had the highest concentration followed by meat eaters and vegetarians. This might be due to their lack of ingestion of dairy foodstuffs, which are believed to lower UA concentrations.[12].

In humans yield of UA relies on purine uptake[13] and a purine-ample diet (such as veal, bacon, kid meat, mutton, turkey, pork, duck, goose, etc) would be responsible for rising only 1 to 2 mg/dL of uric acid[14] whereas diary foodstuff intake has a reciprocal relation with uric acid.[15,10] Since dairy products are low in purine content and it may perform its urate-lowering effect by increasing the elimination of uric acid and its precursor xanthine.[12]

The results of our study also presented that the oxidative stress marker, serum MDA level was high in NV compared to V among HT, preHT and control group but this difference was not statistically significant ($p>0.05$). This is in accordance with the findings of Somannavari MS & Kodliwadmath MV[16] but they found that the difference was significant. Whereas Szeto et al.[17]shown that there was no significant change of MDA level between V and NV. The increased oxidative stress and associated oxidative damage are mediators of renovascular injury in cardiovascular pathologies.[18] Dierckx et al.[19] concluded that serum MDA level (a marker of lipid peroxidation) was significantly increased in NV, as their diet is good resource of iron and copper and these transitional metals in the diet have important role in the initiation and progression of lipid peroxidation. Further these findings were confirmed by Sagare SM et al.[20] This may be due to higher and habitual consumption of fruit and vegetables, dark and whole grain products, grain sprouts, plant oils and oil seeds plentiful in trace elements like zinc, copper and selenium, mono and polyunsaturated fatty acids, antioxidant vitamins, fibers, complex carbohydrates and flavonoids by vegetarians.

The diminished risk of diseases found among vegetarians suggests that biological processes are molded by diet.[21] Therefore, much attention is currently focused on the beneficial effect of vegetarian versus non-vegetarian diet.[22,23] Efficient lifestyle modification may reduce blood pressure as much as a single antihypertensive drug. Combinations of two or more lifestyle alterations can accomplish even better results.[24]

Conclusion

The present study indicates that vegetarian nutrition provides sufficient antioxidants which efficaciously prevent the free radical generation and thus responsible for better antioxidant status and decreased oxidative stress. Maintenance of the oxidative balance in hypertensive patients would be helpful in preventing the CVD and other diseases associated with hypertension. Therefore, our study emphasizes the monitoring of the blood pressure, oxidative stress parameters (SUA and serum MDA level) at regular interval for therapeutic interventions. Moreover, the progress of disease could be prevented by giving proper education to the patient about healthy lifestyle and also advising them to practice yoga, aerobics, walk etc.

Significance of Dietary Pattern in Oxidative Stress among Newly Diagnosed Essential Hypertension

Chanchal Shrivastav[1], Suman Sharma[2], G. Indra Kumar[3]

[1]Associate Professor, Department of Physiology, Ananta Institute of Medical Sciences and Research Center, Rajsamand, Rajasthan, [2]Associate Professor, Department of Physiology, Geetanjali Medical College and Hospital, Udaipur, Rajasthan, [3]Assistant Professor, Department of Physiology, Ananta Institute of Medical Sciences and Research Center, Rajsamand, Rajasthan

Abstract

Background: Hypertension is a significant global public health problem and it is associated with increased oxidative stress. Oxidative stress is disequilibrium between tissue oxidants (free radicals or reactive oxygen species ROS) and antioxidants and may be an integrative mechanism in the progress of cardiovascular diseases (CVD).

Aims & Objectives: To study the impact of dietary pattern on oxidative stress markers in newly diagnosed essential hypertension.

Material and Method: The study was conducted on 75 cases of essential hypertension (HT), 75 prehypertensives (preHT) and 50 control subjects for 15 months. After screening, serum uric acid (SUA) and serum malondialdehyde (S.MDA) level were investigated in both vegetarians (V) and nonvegetarians (NV) in all groups.

Findings: The difference in mean ± SD of SUA and S. MDA level between control, preHT and HT group were found to be highly significant ($p<0.0001$). SUA and S. MDA level was higher in NV as compared to vegetarians in all groups but significant results were found in case of SUA ($p<0.001$).

Conclusion: Long-term vegetarians have improved antioxidant status and coronary heart disease risk profile than do apparently healthy omnivores.

Keywords: *Hypertension, prehypertension, oxidative stress, serum uric acid, serum malondialdehyde, vegetarians, nonvegetarians, systolic blood pressure (SBP), diastolic blood pressure (DBP) .*

Introduction

Hypertension is one of the most important public health challenge world-wide because of its high incidence and associated risks of cardiovascular disease for instance stroke, myocardial infarction and heart failure. Although it has frequently been indicated that the causes of essential hypertension are not known, this is only partially true. Essential hypertension is a heterogeneous disorder, with different patients having different causal factors that lead to high blood pressure. Vascular oxidative stress has been shown in genetic and experimental models of hypertension.[1] In search for a causative factor for essential hypertension, uric acid and lipid peroxidation due to increased oxidative stress are considered.

Although serum uric acid is regarded to be an antioxidant within its normal physiological conditions, it might be accountable for production of free radicals directly or indirectly in hypertensive. Hyperuricaemia (plasma uric acid level more than 6.8 mg/dl at

physiological temperature (37°C) and neutral pH)[2] has been found to be associated with subsequent morbidity and mortality in the general population among patients with congestive heart failure, diabetics and hypertensive patients. Moreover, hyperuricaemia has also been linked to multiple proatherogenic processes, including increased oxidative stress. In recent years, oxidative stress due to ROS is implicated in the pathogenesis of ample variety of diseases like cancer, cataract, diabetes mellitus, rheumatoid arthritis, atherosclerosis, hypertension.[3] In addition the reasons for augmented rate of hypertension include life style changes, sugar rich diet, high fat processed foods and sedentary behavior.[4]

Rapid changes in diets and lifestyles that have took place with urbanization, industrialization and economic advancement have intensified over the past decade. Because of these changes, chronic diseases like hypertension are becoming increasingly significant cause of impairment and premature death.

Material & Method

A hospital based case control study was conducted among 200 subjects of age group between 20–50 years, irrespective of sex in the department of Physiology, Geetanjali medical college & hospital (GMCH), Udaipur.

Inclusion criteria: All the subjects were chosen randomly and following groups were made according to JNC7 criteria

Control group: 75 normotensive subjects

PreHT group: 75 cases of prehypertension

HT group: 75 cases of newly diagnosed cases of essential hypertension with SBP= 140-159 mmHg, DBP= 90-99 mmHg.

Exclusion criteria:

Patients with secondary hypertension, gout, diabetes mellitus, gestational hypertension, and patients taking antihypertensive, smokers and alcohol consumers were excluded from the study.

After obtaining ethical approval (Ref. No. GU/UCE/EC/2013/299 dated 15/05/2013), a written voluntary informed consent was obtained from all the subjects. Then all the subjects were screened as per the detailed history, routine physical examination and appropriate tests. After screening, blood sample (5 ml) was drawn in to a plain vial after an overnight fast (12 hrs) by antecubital venous puncture from all the subjects. Then serum was separated by a centrifugation at 3000rpm for 10 minutes. After that serum sample was used for following biochemical analysis.

Serum Uric Acid: By Modified Trinder Method.[5]

Serum Malondialdehyde (MDA): Thiobarbituric acid (TBA) assay method.[6]

Statistical Analysis: The data were analyzed by using Statistical Package for the Social Sciences (SPSS) Version 16.0. Difference between the groups was analyzed by Analysis of variance test (ANOVA). Diet wise comparison of oxidative stress parameters were tested by Student t-test with p value <0.05 is considered as statistically significant.

Findings

Table: 1 Characteristics of study population among different groups (Mean ±SD)

Variables	Control	Pre HT Group	HT Group	Anova P Value
Age (Yrs.)	37.46 ± **8.09**	35.84 ± **6.5**	40.25 ± 7.71	<0.001
Veg./ Nonveg.	68/32	51/49	40/60	-
SBP (mmHg)	114.06 ± **16.77**	134.00 ± **5.1**	160.04 ± **11.49**	<0.0001
DBP (mmHg)	74.66 ± **6.23**	86.45 ± **2.93**	92.00 ± **10.15**	<0.0001

The difference in mean ± SD of SBP & DBP between three groups were highly significant (p<0.0001).

Table: 2 Diet wise variation of SBP among different groups (Mean ± SD)

	Control			PreHT			HT		
Diet	**Mean**	**SD**	**N**	**Mean**	**SD**	**N**	**Mean**	**SD**	**N**
Non Veg	114.62 ± 6.37		16	134.38 ± 5.01		37	161.82 ± 12.52		45
Veg	112.88 ± 5.84		34	133.63 ± 5.24		38	157.37 ± 9.33		30
T value	0.92			0.63			1.76		
P value	NS			NS			NS		

Table: 3 Diet wise variation of DBP among different groups (Mean ± SD)

	Control			PreHT			HT		
Diet	**Mean**	**SD**	**N**	**Mean**	**SD**	**N**	**Mean**	**SD**	**N**
Nonveg	75.21 ± 6.75		16	87.27 ± 2.83		37	92.44 ± 11.17		45
Veg	73.50 ± 5.99		34	86.63 ± 3.05		38	91.33 ± 9.68		30
T value	0.87			0.94			0.46		
P value	NS			NS			NS		

The table no. 2 & 3 showed that mean ± SD value of both SBP and DBP were higher in NV as compared to V among all three groups but the results were not significant (p>0.05)

Table: 4 Comparison of SUA and S. MDA level among different groups (Mean ± SD)

Variables	Control	Pre HT Group	HT Group	Anova P Value
S. Uric acid (mg/dL)	4.91 ± 0.97	5.90 ± 0.97	6.56 ± 0.76	<0.0001
S. MDA (nmol/mL)	1.30 ± 0.20	1.63 ± 0.28	2.14 ± 0.42	<0.0001

The difference in mean ± SD of SUA and S. MDA level between control, preHT and HT group were found to be highly significant (p<0.0001).

Table: 5 Diet wise variation of SUA level among different groups (Mean ± SD)

Diet	**Control**			**Pre HT group**			**HT Group**		
	Mean	**SD**	**N**	**Mean**	**SD**	**N**	**Mean**	**SD**	**N**
Non veg	5.65 ± 0.77		16	6.55 ± 0.80		37	6.77 ± 0.59		45
Veg.	4.56 ± 0.69		34	5.24 ± 0.53		38	6.19 ± 0.56		30
T value	4.82			8.34			4.25		
P value	<0.0001			<0.0001			<0.001		

Mean ± SD of SUA was significantly higher in NV as compared to vegetarians in all groups (p<0.001).

Table: 6 Diet wise variation of S. MDA level among different groups (Mean ±SD)

Diet	Control			Pre HT group			HT Group		
	Mean	SD	N	Mean	SD	N	Mean	SD	N
Non veg	1.33 ± 0.19		16	1.68 ± 0.27		37	2.20 ± 0.43		45
Veg.	1.28 ± 0.21		34	1.57 ± 0.27		38	2.04 ± 0.39		30
T value	0.84			1.76			1.67		
P value	NS			NS			NS		

Mean ± SD of S.MDA level was higher in NV as compared to V among HT, preHT and control group but this difference was not statistically significant ($p>0.05$).

Discussion

There is a close relationship between the diet and chronic degenerative diseases such as obesity, hypercholesterolemia and hypertension. Our study showed that NV had higher mean SBP and DBP than V in HT, preHT and control group but the results were not significant ($p>0.05$). Our results were similar to the study of Nande PJ et al.[7] but they found significant results in case of DBP ($0.01<p<0.05$). These findings are steady with the results of the DASH (Dietary Approaches to Stopping Hypertension) trial, that a dietary pattern plenteous in fruits, vegetables, low fat dairy products and with abbreviated total and saturated fat can be efficient in the suppression of hypertension.[8] Diet represents a significant role in the primary suppression of hypertension. It is a conception that the non vegetarian diet comprises cholesterol and saturated fatty acids and these are the root cause of problems like coronary heart diseases and hypertension. Vegetarian diets are normally ample in carbohydrates, n-6 fatty acids and dietary fiber and are more helpful in preventing, treating or reversing heart disease. Lifestyle adjustments in diet are playing important role in determining the outcome for people with hypertension.[9]

In the present study serum uric acid level was found to be significantly high in NV as compared to vegetarians among HT, preHT and control group ($p<0.001$). Choi HK et al.[10] also noticed that SUA level enhanced with increasing total meat or sea food intake and diminished with increasing dairy intake. Similarly Schmidt JA et al.[11] found that vagan had the highest concentration followed by meat eaters and vegetarians. This might be due to their lack of ingestion of dairy foodstuffs, which are believed to lower UA concentrations.[12].

In humans yield of UA relies on purine uptake[13] and a purine-ample diet (such as veal, bacon, kid meat, mutton, turkey, pork, duck, goose, etc) would be responsible for rising only 1 to 2 mg/dL of uric acid[14] whereas diary foodstuff intake has a reciprocal relation with uric acid.[15,10] Since dairy products are low in purine content and it may perform its urate-lowering effect by increasing the elimination of uric acid and its precursor xanthine.[12]

The results of our study also presented that the oxidative stress marker, serum MDA level was high in NV compared to V among HT, preHT and control group but this difference was not statistically significant ($p>0.05$). This is in accordance with the findings of Somannavari MS & Kodliwadmath MV[16] but they found that the difference was significant. Whereas Szeto et al.[17]shown that there was no significant change of MDA level between V and NV. The increased oxidative stress and associated oxidative damage are mediators of renovascular injury in cardiovascular pathologies.[18] Dierckx et al.[19] concluded that serum MDA level (a marker of lipid peroxidation) was significantly increased in NV, as their diet is good resource of iron and copper and these transitional metals in the diet have important role in the initiation and progression of lipid peroxidation. Further these findings were confirmed by Sagare SM et al.[20] This may be due to higher and habitual consumption of fruit and vegetables, dark and whole grain products, grain sprouts, plant oils and oil seeds plentiful in trace elements like zinc, copper and selenium, mono and polyunsaturated fatty acids, antioxidant vitamins, fibers, complex carbohydrates and flavonoids by vegetarians.

The diminished risk of diseases found among vegetarians suggests that biological processes are molded by diet.[21] Therefore, much attention is currently focused on the beneficial effect of vegetarian versus non-vegetarian diet.[22,23] Efficient lifestyle modification may reduce blood pressure as much as a single antihypertensive drug. Combinations of two or more lifestyle alterations can accomplish even better results.[24]

Conclusion

The present study indicates that vegetarian nutrition provides sufficient antioxidants which efficaciously prevent the free radical generation and thus responsible for better antioxidant status and decreased oxidative stress. Maintenance of the oxidative balance in hypertensive patients would be helpful in preventing the CVD and other diseases associated with hypertension. Therefore, our study emphasizes the monitoring of the blood pressure, oxidative stress parameters (SUA and serum MDA level) at regular interval for therapeutic interventions. Moreover, the progress of disease could be prevented by giving proper education to the patient about healthy lifestyle and also advising them to practice yoga, aerobics, walk etc.

Knowledge, Attitude and Practice for Prevention and Treatment of Swine Flu in Population of Udaipur City

Paras Arvindbhai Parekh[1], Chanchal Shrivastav[1], G Indra Kumar[2]

[1]Associate Professor, [2]Assistant Professor, Department of Physiology, Ananta Institute of Medical Sciences and Research Center, Rajasthan

Abstract

Background: Swine flu has become a very common seasonal respiratory disease having larger number of morbidities and mortalities. It has created panic situation among general public and health care workers just because of lack of awareness regarding the same.

Aims & Objectives: This study was carried out to reach general public of every class for their perception for this pandemic disease. Knowledge regarding measures for prevention and treatments available if it occurs was the objective of this study. Also to find out myths prevalent in them and to create awareness in proper direction was the objective of this study.

Material and Method: This study was carried out on 500 people chosen randomly from different places of Udaipur having different class and strata. Study was done by making pre-formed questionnaires. Data was analyzed by using SPSS.

Findings: Major part of study population gain information from news papers and TV channels. 76% of study population had heard about swine flu by different resources. Myths are prevalent in 37% of populations regarding causes and mode of occurring of swine flu. Only 23% of study population knows importance of hand-washing as measure for preventing swine flu.

Conclusion: Though large campaign carried out by government and media, people needs to be made aware for every aspects of swine flu through ground level awareness programmes.

Keywords: *Swine flu, knowledge, attitude, practice.*

Introduction

Swine influenza is an acute respiratory disease occurs due to different strains of influenza virus type A which is named globally as H1N1.[1] Initially virus outbreak was prevalent only in pigs but due to regular contacts between pigs and human, some strains had spread from pigs to human. In 21st century first outbreak of this H1N1 flu occurred in Maxico city in the month of March 2009, after that it spread within a very limited time to all over the world.[1] After that outbreak, World health organization (WHO) had declared it as pandemic as it had approached in more than two continents.[2] It was given a name 'swine flu' as during 2009 pandemic, the strain of H1N1 influenza showed very similar genes to the influenza virus affecting North American swine.[3,4]

Considering amongst the largest populist country, India is on 3rd rank according to the number of cases and total number of deaths because of swine flu.[5] Due to increasing numbers of morbidities and mortalities in subsequent years, swine flu is considered as global threat amongst emerging diseases. According to data of Ministry of health and family welfare, government of India, 6,804 cases and 542 deaths from swine flu has been registered up to October 2018.[6] Rajasthan reported 191 deaths from swine flu amongst 1912 cases with

second most after Maharashtra in the year of 2018.[6]

Material & Method

This is a cross-sectional study carried out on general public of Udaipur city. For knowledge, attitude and practice study, sample size should be atleast 200.[7] In this study total 500 participants were included so as to achieve larger representation of population. Study was carried out during October-December 2018.

Study was approved by institutional ethical committee. Inclusion criteria for participants were minimum 15 years of age with at least primary education achieved. To make this study more representative of population, participants were selected from different parts of city having different economic status, different educational level and different occupations like some professional persons working as company executives, lawyer, bankers, and also some shopkeepers, street vendors, students, housewife etc. Random sampling was done for selection. Informed consent was taken from participants. None of the participant refused as they were assured for complete anonymous study.

Participants were approached personally for interview. Pre formed questionnaires were used which includes their demographic profile (sex, age, education, occupation), knowledge regarding swine flu (how it occurs, mode of spreading, signs and symptoms), attitude towards disease and practice they follow for prevention and treatment of disease.

Findings

In the present study 346 participants were male and 154 were female. Educational levels of participants were from primary to professional level with different job profile.

Table-1: Knowledge on symptoms of swine flu

Symptoms	No.	Percentage
Fever	390	89.1
Running nose	85	19.4
Cough	375	85.6
Headache	128	29.2
Body ache	143	32.6
Vomiting	76	17.3
Diarrhea	74	16.8

Amongst 500 participants, 438 (87.6%) had previously heard about swine flu so further interview was carried out for these 438 participants only. 190 (43.3%) knew that swine flu is caused by virus. The most common symptoms of swine flu like running nose was known to 85 participants (19.4%), fever to 390 (89.1%) and cough to 375 (85.6%) participants. (Table-1)

Table-2: How to prevent swine flu?

Preventive measures	No.	Percentage
Face mask	323	73.7
Frequent hand wash	157	35.8
Avoid crowded place	193	44.1
By home remedies	146	33.3
By homeopathic drugs	82	18.7
Avoiding animal contacts	107	24.4

Regarding preventive measures, use of mask or handkerchief was known to 323 (73.7%), frequent hand washing and personal hygiene 157 (35.8%) while 193 (44.1%) participants believe that avoid crowded place for prevention. (Table-2)

Table-3: How swine flu spread?

Mode of spread	No.	Percentage
Contact of patient	316	72.1
Non-vegetarian food	34	7.7
Bite of bugs	26	5.9
Blood contact of patient	43	9.8
Through water	21	4.7

Myths or misconception regarding swine flu are by eating non-vegetarian food 34 (7.7%), bite of some bugs 26 (5.9%), blood contact of infected patient 43 (9.8%), while majority of participants 316 (72.1%) were aware that swine flu spread by close contact with affected person and by inhalation through respiratory route when patient cough or sneeze. (Table-3)

Table-4: Sources of information

Sources	No.	Percentage
Television	196	44.7
News paper	180	41.1
Internet	88	20.1
Doctors	32	7.3
Social media	71	16.2
Hoardings and banners	60	13.6
Programmes by health department	19	4.3

Participants have different sources of information with telemedia is the highest 196 (44.7%). (Table-4)

Knowledge regarding vaccine available for swine flu was known to 171 (39.1%) participants and treatment availability was known to 236 (53.8%) but only 29 (6.6%) participants have heard the name of drug Tamiflu.

Discussion

Knowledge regarding infectious disease among community people is the benchmark of incidence and prevalence of that disease. Right attitude and practice towards the disease make them less vulnerable and ultimately it decides well being of any community. This study is based on knowledge, attitude and practice for prevention and treatment of swine flu (H1N1) amongst urban community of Udaipur city which may help local authorities related to health sectors for planning and implementing programme for awareness regarding swine flu. Some misconceptions must be removed from general public like swine flu is always deadly disease and no any treatment available.

In this study 87.6% participants have heard about swine flu which is lower than study done by Chaudhary V et al[8] and Rathi S et al[9] while it is higher than study done by Singh S et al[10] which may be due to different educational level of participants and awareness programmes by local authorities at different places. Study population represents all aspects of community with wide variety of demographic profiles. Male participants are more in numbers which is similar to study done by Singh S et al[10] while in study of Latiff et al[11] female participants are more.

Knowledge on clinical features of swine flu amongst participants of this study is found to be similar to study done by Farhat et al[12] with fever is known to be the most common symptoms while another common symptom of running nose is not much known amongst participants.

Prevention is always considered as more important tool than treatment. In this study 73.7% participants consider use of face mask as the best method for prevention but another much important measure of frequent hand washing is known only to 35.8% which is contrast to study done by Rubin et al.[13] This is because lack of interest and lazy attitude towards disease and awareness programmes run by authorities.

Myths also prevalent amongst participants like eating of non vegetarian food specially pork, bite of mosquito or other bugs or by taking contaminated food or water which contradict to study done by Shilpa K et al[14] in Karnataka having very low 2.4% prevalence of myths . This may be due to failure of health workers and authorities in making ground level efforts for spreading awareness regarding actual cause and mode of disease.

Telemedia and newspapers are major source of information as better availability of these resources in urban population similar to findings of other studies.[5,12,15] Health education is very important measure for increase well being of community by reducing prevalence of disease. Mass media including social media is considered best in current scenario to approach every individual of society.

Conclusion

If *knowledge* regarding swine flu is increased, it definitely changes *attitude* of community towards disease and *practice* of preventive measures to be taken. These are three pillars of health system as it directly affects health programmes implemented by government. Focal points regarding swine flu like running nose as important symptoms, frequent hand washing as important practice and removing all myths for disease are key areas to be considered and mass media can help during epidemic of swine flu for creating awareness of these key areas instead of creating panics and blaming health authorities. Also role of health workers and concerned authorities is important as early detection and timely notification of disease can help to break chain of spreading of

disease. This study conclude that there is either lack of knowledge or incomplete knowledge regarding swine flu in general public which is to be rectified by paying immediate attention

Effect of Treadmill Exercise on Blood Glucose Control in Type-2 Diabetes Mellitus Patients

Paras Arvindbhai Parekh

Assistant Professor, Department of Physiology, Ananta Institute of Medical Sciences and Research Center, Rajasthan

Abstract

Background: Diabetes mellitus type 2 is because of resistance to insulin resulting in inability to utilize glucose. In addition to medicines and diet control, regular exercise helps in increase in utilization of glucose.

Aims & Objectives: To study efficacy of exercise especially treadmill walking on controlling blood glucose homeostasis in diabetes mellitus.

Material and Method: The study was conducted on 40 clinically confirmed cases of type-2 diabetes mellitus male patients who were divided in study group and control group with 20 patients in each group. Study was conducted for period of 8 weeks. Diet plan was formed by expert during this period and subjects were instructed to follow it strictly. Fasting blood glucose and postprandial blood glucose was measured before and after exercise programme.

Findings: There is significant decrease in fasting blood glucose and Postprandial blood glucose level in study group as compared to control group with inter-group difference was significant ($P<0.05$).

Conclusion: Treadmill exercise is very useful for blood glucose control in addition to diet control and medicines.

Keywords: *Type-2 diabetes mellitus, Treadmill exercise, Fasting blood glucose, Postprandial blood glucose, Glycemic control.*

Introduction

Diabetes mellitus (DM) refers to a group of common metabolic disorders that share the phenotype of hyperglycemia. The two broad categories of DM are designated type 1 and type 2. Both types of diabetes are preceded by a phase of abnormal glucose homeostasis as the pathogenic processes progress. Type 1 DM is the result of complete or near-total insulin deficiency. Type 2 DM is a heterogeneous group of disorders characterized by variable degrees of insulin resistance, impaired insulin secretion, and increased glucose production.[1]

Corresponding Author:

Email: paras_parekh13@yahoo.com

The prevalence of diabetes is going to double globally from 171 million in 2000 to 366 million in 2030 with maximum increase in India. By 2030, around 79.4 million people will be affected by diabetes according to prediction made by Wild et al.[2]

In addition to medication and diet control, exercise is also helpful in increasing insulin sensitivity. American diabetes association recommends moderate aerobic physical activity of 150 minutes/week.[3] Walking is considered to be the best exercise as it involves larger muscles of lower limb as well as muscular work of upper limb. Treadmill machine which is electronically driven or manual simulates all the features of natural walking.

Material & Method

In our study we used treadmill (Phillips, Novafit turbo) machine, oscilloscope for measuring heart rate and respiratory rate, Sphygmomanometer for measuring

blood pressure, weighing scale. Permission from institutional ethical committee was taken.

From diabetes OPD 40 male patients of age group 45-55 years who were clinically and biochemically confirmed cases of diabetes included in study after obtaining informed consent. Patients with known case of cardiac, respiratory, renal and musculoskeletal disorders were excluded from programme. Those who were willing to do exercise were included in study group and who were not willing to do exercise were included in control group.

Whole programme was conducted for period of 8 weeks. At the beginning of study, fasting blood sugar (FBS) and postprandial blood sugar (PPBS) was measured for all subjects. Additionally weight, height and body mass index was measured. Subjects were examined for any muscular weakness in lower limb. Regular diet may vary in different subjects so diet plan was formed for whole day by advice of dietician and they were explained to follow it strictly during the whole exercise programme so as to avoid effects of diet on blood glucose level.

Treadmill machine (Phillips, Novafit turbo) used for the study can measure speed in form of RPM, total distance travelled in kilometers and calories used during exercise. All subjects in study group were first given demonstration of treadmill machine to make them familiarize. Programme was conducted for total 40 minutes which include 5 minutes of warm up, 30 minutes of treadmill walking followed by 5 minutes of rest. All subjects were instructed to report immediately if they feel breathlessness, headache, dizziness or any other symptoms which are indicative for stopping exercise. Blood pressure, heart rate and respiratory rate were taken in supine at the beginning of exercise.

First warm up was done in the form of active limb movements and muscle stretching. Then oscilloscope was attached for monitoring of heart rate, respiratory rate and blood pressure. Subjects were instructed to walk on treadmill for 30 minutes. Speed of treadmill machine was set to 3.5 km/hour with fixed inclination. All the subjects were constantly monitored for development of any symptoms and any noticeable change in parameters. At the end of thirty minutes, parameters were measured immediately and then they are instructed to take rest for five minutes. Vital parameters were also taken during recovery period of five minutes. This completed session was conducted for five days in a week for total 8 weeks. At the end of 8 weeks FBS and PPBS was taken again for both groups. Statistical analysis was done using student's t test with p value < 0.05 is considered as statistically significant.

Findings

All the subjects in study group completed exercise programme without any event. Pre and post exercise blood glucose levels are compared in both study and control group.

In study group, FBS and PPBS level before exercise was in the range of 150-196 mg% and 180-212 mg% respectively. After exercise programme range of FBS and PPBS was 130-162 mg% and 156-170 mg% respectively.

In control group, FBS and PPBS level before exercise was in the range of 154-202 mg% and 184-210 mg% respectively. After 8 weeks of observation range of FBS and PPBS was 150-188 mg% and 168-200 mg% respectively.

Difference between FBS and PPBS before and after programme in both the group was compared (Table-1). Mean decrease in FBS in study group was 38.6 mg% while in control group it was 26.8 mg% with intergroup difference is statistically significant ($p<0.05$). In study group decrease in PPBS was 42.8mg% as compared to control group having difference of 30.4 mg%. So inter group difference in PPBS is statistically significant (p value <0.05). Also subjects in study group reported of feeling of well being with loss of average two kilograms weight.

Table-1 Comparison between study and control group for change in FBS and PPBS after programme

Difference	Study group (mean±SD) Control group (mean±SD) n=10
FBS1-FBS2	38 ± 8.275 26 ± 8.910*
PPBS1-PPBS2	42 ± 6.784 30 ± 8.623*
FBS1- Fasting blood glucose before exercise FBS2- Fasting blood glucose after exercise PPBS1- Postprandial blood glucose before exercise PPBS2- Postprandial blood glucose after exercise *p<0.05, student t-test	

Discussion

Diabetes Mellitus is a clinical syndrome comprising a heterogeneous group of metabolic diseases that are characterized by chronic hyperglycemia and disturbances in carbohydrate, fat and protein metabolism secondary to defects in insulin secretion, insulin action or both.[4] Comprehensive management of diabetes includes drugs, insulin, lifestyle changes comprising of diet control, exercise and education.[5] In this study, efficacy of treadmill exercise on control of blood glucose was studied in addition to diet control and medication. Exercise improves insulin sensitivity and therefore has a positive effect on blood glucose control. In addition it also has positive effects on lipid profile and blood pressure and it is important part of weight management programme. For inactive person it is better to start with at least 5 minutes daily and then gradually increase 5 minutes to up to at least 30 minutes of daily walking.[6] Only problem with diet and exercise is that it requires strong motivation and self confidence. So for the patient's perspective oral drugs for diabetes is the best management.

At the beginning of exercise, muscle utilizes stored glycogen as fuel consumption. But it is available only for short period only. If activity is continued, glycogenolysis becomes source of glucose and then after few minutes gluconeogenesis starts in liver. After depletion of glycogen store in liver, stored fat in adipose tissue converted into fatty acids which are used as fuel by muscle.[7]

Wahren et al. reported that working muscles are more sensitive to insulin as compared to resting muscle, which increase utilization of glucose. Also during exercise blood flow to working muscle increase which increase size of capillaries and number of insulin receptors which ultimately balance sensitivity of insulin.[8]

Shivananda nayak et al. reported that after six weeks of treadmill exercise, glucose utilization is increased in muscle which has positive effects on glucose homeostasis with significant fall in fasting and postprandial blood glucose level.[9]

Exercise programme is also affected by some factors like type of exercise, duration of exercise, intensity and frequency of exercise. According to American college of sports medicine, exercise with low intensity but long duration gives better result as compared to high intensity short duration exercise. Duration of exercise should be gradually increased over days. Exercise programme should be restricted to five days per week. Intensity can be controlled by counting target heart rate with formula of subtracting your age from 220. In this study it was found that endurance exercise helps in control of blood glucose level. It works by increasing insulin sensitivity in exercising muscle. As compared to resting condition, numbers of insulin receptors are more in working muscle which ultimately helps to utilize glucose despite low production by pancreas as in diabetes mellitus.

Conclusion

Well planned exercise programme which is strictly followed can improve glycemic control and also helps to reduce weight. In addition to mental well being it reduces cardiovascular risk factors in patients of diabetes mellitus.

Knowledge, Attitude and Practice for Prevention and Treatment of Swine Flu in Population of Udaipur City

Paras Arvindbhai Parekh[1], Chanchal Shrivastav[1], G Indra Kumar[2]

[1]Associate Professor, [2]Assistant Professor, Department of Physiology, Ananta Institute of Medical Sciences and Research Center, Rajasthan

Abstract

Background: Swine flu has become a very common seasonal respiratory disease having larger number of morbidities and mortalities. It has created panic situation among general public and health care workers just because of lack of awareness regarding the same.

Aims & Objectives: This study was carried out to reach general public of every class for their perception for this pandemic disease. Knowledge regarding measures for prevention and treatments available if it occurs was the objective of this study. Also to find out myths prevalent in them and to create awareness in proper direction was the objective of this study.

Material and Method: This study was carried out on 500 people chosen randomly from different places of Udaipur having different class and strata. Study was done by making pre-formed questionnaires. Data was analyzed by using SPSS.

Findings: Major part of study population gain information from news papers and TV channels. 76% of study population had heard about swine flu by different resources. Myths are prevalent in 37% of populations regarding causes and mode of occurring of swine flu. Only 23% of study population knows importance of hand-washing as measure for preventing swine flu.

Conclusion: Though large campaign carried out by government and media, people needs to be made aware for every aspects of swine flu through ground level awareness programmes.

Keywords: *Swine flu, knowledge, attitude, practice.*

Introduction

Swine influenza is an acute respiratory disease occurs due to different strains of influenza virus type A which is named globally as H1N1.[1] Initially virus outbreak was prevalent only in pigs but due to regular contacts between pigs and human, some strains had spread from pigs to human. In 21st century first outbreak of this H1N1 flu occurred in Maxico city in the month of March 2009, after that it spread within a very limited time to all over the world.[1] After that outbreak, World health organization (WHO) had declared it as pandemic as it had approached in more than two continents.[2] It was given a name 'swine flu' as during 2009 pandemic, the strain of H1N1 influenza showed very similar genes to the influenza virus affecting North American swine.[3,4]

Considering amongst the largest populist country, India is on 3rd rank according to the number of cases and total number of deaths because of swine flu.[5] Due to increasing numbers of morbidities and mortalities in subsequent years, swine flu is considered as global threat amongst emerging diseases. According to data of Ministry of health and family welfare, government of India, 6,804 cases and 542 deaths from swine flu has been registered up to October 2018.[6] Rajasthan reported 191 deaths from swine flu amongst 1912 cases with

Corresponding Author:
Chanchal Shrivastav
Mobile no. 9079663696
Email: chanchalshrivastav29811@gmail.com

second most after Maharashtra in the year of 2018.[6]

Material & Method

This is a cross-sectional study carried out on general public of Udaipur city. For knowledge, attitude and practice study, sample size should be atleast 200.[7] In this study total 500 participants were included so as to achieve larger representation of population. Study was carried out during October-December 2018.

Study was approved by institutional ethical committee. Inclusion criteria for participants were minimum 15 years of age with at least primary education achieved. To make this study more representative of population, participants were selected from different parts of city having different economic status, different educational level and different occupations like some professional persons working as company executives, lawyer, bankers, and also some shopkeepers, street vendors, students, housewife etc. Random sampling was done for selection. Informed consent was taken from participants. None of the participant refused as they were assured for complete anonymous study.

Participants were approached personally for interview. Pre formed questionnaires were used which includes their demographic profile (sex, age, education, occupation), knowledge regarding swine flu (how it occurs, mode of spreading, signs and symptoms), attitude towards disease and practice they follow for prevention and treatment of disease.

Findings

In the present study 346 participants were male and 154 were female. Educational levels of participants were from primary to professional level with different job profile.

Table-1: Knowledge on symptoms of swine flu

Symptoms	No.	Percentage
Fever	390	89.1
Running nose	85	19.4
Cough	375	85.6
Headache	128	29.2
Body ache	143	32.6
Vomiting	76	17.3
Diarrhea	74	16.8

Amongst 500 participants, 438 (87.6%) had previously heard about swine flu so further interview was carried out for these 438 participants only. 190 (43.3%) knew that swine flu is caused by virus. The most common symptoms of swine flu like running nose was known to 85 participants (19.4%), fever to 390 (89.1%) and cough to 375 (85.6%) participants. (Table-1)

Table-2: How to prevent swine flu?

Preventive measures	No.	Percentage
Face mask	323	73.7
Frequent hand wash	157	35.8
Avoid crowded place	193	44.1
By home remedies	146	33.3
By homeopathic drugs	82	18.7
Avoiding animal contacts	107	24.4

Regarding preventive measures, use of mask or handkerchief was known to 323 (73.7%), frequent hand washing and personal hygiene 157 (35.8%) while 193 (44.1%) participants believe that avoid crowded place for prevention. (Table-2)

Table-3: How swine flu spread?

Mode of spread	No.	Percentage
Contact of patient	316	72.1
Non-vegetarian food	34	7.7
Bite of bugs	26	5.9
Blood contact of patient	43	9.8
Through water	21	4.7

Myths or misconception regarding swine flu are by eating non-vegetarian food 34 (7.7%), bite of some bugs 26 (5.9%), blood contact of infected patient 43 (9.8%), while majority of participants 316 (72.1%) were aware that swine flu spread by close contact with affected person and by inhalation through respiratory route when patient cough or sneeze. (Table-3)

Table-4: Sources of information

Sources	No.	Percentage
Television	196	44.7
News paper	180	41.1
Internet	88	20.1
Doctors	32	7.3
Social media	71	16.2
Hoardings and banners	60	13.6
Programmes by health department	19	4.3

Participants have different sources of information with telemedia is the highest 196 (44.7%). (Table-4)

Knowledge regarding vaccine available for swine flu was known to 171 (39.1%) participants and treatment availability was known to 236 (53.8%) but only 29 (6.6%) participants have heard the name of drug Tamiflu.

Discussion

Knowledge regarding infectious disease among community people is the benchmark of incidence and prevalence of that disease. Abstract

Background: Swine flu has become a very common seasonal respiratory disease having larger number of morbidities and mortalities. It has created panic situation among general public and health care workers just because of lack of awareness regarding the same.

Aims & Objectives: This study was carried out to reach general public of every class for their perception for this pandemic disease. Knowledge regarding measures for prevention and treatments available if it occurs was the objective of this study. Also to find out myths prevalent in them and to create awareness in proper direction was the objective of this study.

Material and Method: This study was carried out on 500 people chosen randomly from different places of Udaipur having different class and strata. Study was done by making pre-formed questionnaires. Data was analyzed by using SPSS.

Findings: Major part of study population gain information from news papers and TV channels. 76% of study population had heard about swine flu by different resources. Myths are prevalent in 37% of populations regarding causes and mode of occurring of swine flu. Only 23% of study population knows importance of hand-washing as measure for preventing swine flu.

Conclusion: Though large campaign carried out by government and media, people needs to be made aware for every aspects of swine flu through ground level awareness programmes.

Keywords: *Swine flu, knowledge, attitude, practice.*

Introduction

Swine influenza is an acute respiratory disease occurs due to different strains of influenza virus type A which is named globally as H1N1.[1] Initially virus outbreak was prevalent only in pigs but due to regular contacts between pigs and human, some strains had spread from pigs to human. In 21st century first outbreak of this H1N1 flu occurred in Maxico city in the month of March 2009, after that it spread within a very limited time to all over the world.[1] After that outbreak, World health organization (WHO) had declared it as pandemic as it had approached in more than two continents.[2] It was given a name 'swine flu' as during 2009 pandemic, the strain of H1N1 influenza showed very similar genes to the influenza virus affecting North American swine.[3,4]

Considering amongst the largest populist country, India is on 3rd rank according to the number of cases and total number of deaths because of swine flu.[5] Due to increasing numbers of morbidities and mortalities in subsequent years, swine flu is considered as global threat amongst emerging diseases. According to data of Ministry of health and family welfare, government of India, 6,804 cases and 542 deaths from swine flu has been registered up to October 2018.[6] Rajasthan reported 191 deaths from swine flu amongst 1912 cases with

second most after Maharashtra in the year of 2018.[6]

Material & Method

This is a cross-sectional study carried out on general public of Udaipur city. For knowledge, attitude and practice study, sample size should be atleast 200.[7] In this study total 500 participants were included so as to achieve larger representation of population. Study was carried out during October-December 2018.

Study was approved by institutional ethical committee. Inclusion criteria for participants were minimum 15 years of age with at least primary education achieved. To make this study more representative of population, participants were selected from different parts of city having different economic status, different educational level and different occupations like some professional persons working as company executives, lawyer, bankers, and also some shopkeepers, street vendors, students, housewife etc. Random sampling was done for selection. Informed consent was taken from participants. None of the participant refused as they were assured for complete anonymous study.

Participants were approached personally for interview. Pre formed questionnaires were used which includes their demographic profile (sex, age, education, occupation), knowledge regarding swine flu (how it occurs, mode of spreading, signs and symptoms), attitude towards disease and practice they follow for prevention and treatment of disease.

Findings

In the present study 346 participants were male and 154 were female. Educational levels of participants were from primary to professional level with different job profile.

Table-1: Knowledge on symptoms of swine flu

Symptoms	No.	Percentage
Fever	390	89.1
Running nose	85	19.4
Cough	375	85.6
Headache	128	29.2
Body ache	143	32.6
Vomiting	76	17.3
Diarrhea	74	16.8

Amongst 500 participants, 438 (87.6%) had previously heard about swine flu so further interview was carried out for these 438 participants only. 190 (43.3%) knew that swine flu is caused by virus. The most common symptoms of swine flu like running nose was known to 85 participants (19.4%), fever to 390 (89.1%) and cough to 375 (85.6%) participants. (Table-1)

Table-2: How to prevent swine flu?

Preventive measures	No.	Percentage
Face mask	323	73.7
Frequent hand wash	157	35.8
Avoid crowded place	193	44.1
By home remedies	146	33.3
By homeopathic drugs	82	18.7
Avoiding animal contacts	107	24.4

Regarding preventive measures, use of mask or handkerchief was known to 323 (73.7%), frequent hand washing and personal hygiene 157 (35.8%) while 193 (44.1%) participants believe that avoid crowded place for prevention. (Table-2)

Table-3: How swine flu spread?

Mode of spread	No.	Percentage
Contact of patient	316	72.1
Non-vegetarian food	34	7.7
Bite of bugs	26	5.9
Blood contact of patient	43	9.8
Through water	21	4.7

Myths or misconception regarding swine flu are by eating non-vegetarian food 34 (7.7%), bite of some bugs 26 (5.9%), blood contact of infected patient 43 (9.8%), while majority of participants 316 (72.1%) were aware that swine flu spread by close contact with affected person and by inhalation through respiratory route when patient cough or sneeze. (Table-3)

Table-4: Sources of information

Sources	No.	Percentage
Television	196	44.7
News paper	180	41.1
Internet	88	20.1
Doctors	32	7.3
Social media	71	16.2
Hoardings and banners	60	13.6
Programmes by health department	19	4.3

Participants have different sources of information with telemedia is the highest 196 (44.7%). (Table-4)

Knowledge regarding vaccine available for swine flu was known to 171 (39.1%) participants and treatment availability was known to 236 (53.8%) but only 29 (6.6%) participants have heard the name of drug Tamiflu.

Discussion

Knowledge regarding infectious disease among community people is the benchmark of incidence and prevalence of that disease. Right attitude and practice towards the disease make them less vulnerable and ultimately it decides well being of any community. This study is based on knowledge, attitude and practice for prevention and treatment of swine flu (H1N1) amongst urban community of Udaipur city which may help local authorities related to health sectors for planning and implementing programme for awareness regarding swine flu. Some misconceptions must be removed from general public like swine flu is always deadly disease and no any treatment available.

In this study 87.6% participants have heard about swine flu which is lower than study done by Chaudhary V et al[8] and Rathi S et al[9] while it is higher than study done by Singh S et al[10] which may be due to different educational level of participants and awareness programmes by local authorities at different places. Study population represents all aspects of community with wide variety of demographic profiles. Male participants are more in numbers which is similar to study done by Singh S et al[10] while in study of Latiff et al[11] female participants are more.

Knowledge on clinical features of swine flu amongst participants of this study is found to be similar to study done by Farhat et al[12] with fever is known to be the most common symptoms while another common symptom of running nose is not much known amongst participants.

Prevention is always considered as more important tool than treatment. In this study 73.7% participants consider use of face mask as the best method for prevention but another much important measure of frequent hand washing is known only to 35.8% which is contrast to study done by Rubin et al.[13] This is because lack of interest and lazy attitude towards disease and awareness programmes run by authorities.

Myths also prevalent amongst participants like eating of non vegetarian food specially pork, bite of mosquito or other bugs or by taking contaminated food or water which contradict to study done by Shilpa K et al[14] in Karnataka having very low 2.4% prevalence of myths . This may be due to failure of health workers and authorities in making ground level efforts for spreading awareness regarding actual cause and mode of disease.

Telemedia and newspapers are major source of information as better availability of these resources in urban population similar to findings of other studies.[5,12,15] Health education is very important measure for increase well being of community by reducing prevalence of disease. Mass media including social media is considered best in current scenario to approach every individual of society.

Conclusion

If *knowledge* regarding swine flu is increased, it definitely changes *attitude* of community towards disease and *practice* of preventive measures to be taken. These are three pillars of health system as it directly affects health programmes implemented by government. Focal points regarding swine flu like running nose as important symptoms, frequent hand washing as important practice and removing all myths for disease are key areas to be considered and mass media can help during epidemic of swine flu for creating awareness of these key areas instead of creating panics and blaming health authorities. Also role of health workers and concerned authorities is important as early detection and timely notification of disease can help to break chain of spreading of

disease. This study conclude that there is either lack of knowledge or incomplete knowledge regarding swine flu in general public which is to be rectified by paying immediate attention

COMPARATIVE STUDY OF LIPID PROFILE AND FASTING BLOOD GLUCOSE AMONG VEGETARIANS AND NON VEGETARIANS

Ravi Bharatkumar Thaker*, Paras Arvindbhai Parekh**

*Assistant professor, Department of Physiology, Pacific medical college and hospital, Udaipur- 313001, Rajasthan.

**Assistant professor, Department of Physiology, Ananta institute of medical sciences and research center, Rajsamand-313202, Rajasthan.

Abstracts: **Background:** Cardiovascular diseases (CVD) one of the major chronic diseases and leading cause of death. One important risk factor for cardiovascular diseases is hyperlipidemia. Our diet determines development of hyperlipidemia to a great extent. **Objective:** Comparison of effect of vegetarian and non vegetarian diet on lipid profile and fasting blood glucose level. **Methods:** Present study was conducted among 100 males of lower middle socioeconomic class of bhuwana village who were divided into two groups based on their diet either vegetarian or non vegetarian. 55 and 45 subjects were included in each group respectively. A questionnaire containing detailed diet history was filled by each subject. Lipid profile and fasting blood sugar were recorded. Data were analysed by applying appropriate statistical test. **Results:** Mean value of total cholesterol, LDL among non vegetarian subjects were 210.60mg/dl, 127.56mg/dl respectively, which was higher than mean value of 171.94mg/dl, 104.46mg/dl respectively in vegetarian group ($P<0.05$). While mean serum triglyceride and HDL was found to be higher in vegetarian subjects which was 135.06mg/dl and 43.47mg/dl, as compared to non vegetarian subjects having mean value of 112.75mg/dl and 41.63mg/dl respectively ($P<0.05$). Fasting blood sugar of vegetarians was 96.48mg/dl while that of non vegetarians was 90.30mg/dl ($p>0.05$) **Conclusion:** Non vegetarian diet alters the lipid profile. Fasting blood glucose is normal in both groups.

Key Words:Fasting blood glucose, hyperlipidemia, lipid profile, non vegetarian, Vegetarian.

Introduction

Cardiovascular diseases (CVD) one of the major chronic disease, which is the leading cause of death. In India, the death rate from CVD has increased at an alarming rate and is estimated currently as 52 per cent[1]. One of the major risk factors for cardiovascular diseases is hyperlipidemia. Cholesterol disorders or scientifically termed dyslipidemia refers to the clinical conditions produced by lipid aberrations, thus raising the cholesterol and triglyceride levels[2, 3]. Recent study says 80% of cholesterol is produced by liver while only 20% is contributed by dietary sources. [4]

There is great dispute whether vegetarian diet is better or non- vegetarian. The natural diet of man consists of fruits, nuts and grains, not meat. Then the question arises why do large numbers of people eat animal flesh? There is a variety of reasons for people having a non-vegetarian diet. Most people are concerned about their health and many people have the think that non-vegetarian foods being rich in protein and iron are the only source for getting all the nutrients that can make them strong, healthy and active. It is also well known fact that many essential amino acids are only available in animal proteins.

Vegetarian diet is that which excludes all food which is cooked from dead animals. Vegetarians do not eat meat or meat products, but may consume milk, dairy products. This diet, when appropriately planned and balanced, is healthful and provides health benefits, because it acts both in the prevention and in the treatment of diseases [5].Saturated fats, such as animal fats and cholesterol play an important role in person's health. Although some fats are necessary in a balanced diet for body maintenance, saturated fats can be hazardous to one's health, if taken in excess amounts. Diets high in saturated fats and cholesterol, increase cholesterol level in blood and produce atherosclerosis, which leads to heart

disease and stroke. Epidemiological studies on vegetarians show that appropriately planned vegetarian diets are healthy and nutritionally adequate[6]. Compared to omnivorous diets, vegetarian diets can provide several health benefits. Vegetarians have a lower prevalence of overweight and obesity also lower risk of IHD, diabetes and diverticular disease compared with non-vegetarians from a similar background, whereas the data are equivocal for stroke. [7] The long-term health of vegetarians appears to be generally good, and for some diseases and medical conditions it may be better than that of comparable omnivores. However, these positive health-related outcomes in vegetarians can be influenced by factors other than dietary practice.

The lipid profile is a blood test done to access the status of fat metabolism in the body and is important in heart diseases. High circulating serum cholesterol, low density lipoprotein- cholesterol (LDL-C) and serum triglycerides are major risk factors of this disease[8].

Aims and objectives:

- Impact of different composition of vegetarian as well as non vegetarian diet on lipid profile and blood glucose.
- To know effect of different composition of non vegetarian diet such as egg, fish, meat on lipid profile.

Material and Methods

Present cross sectional- observational type of study was conducted among 100 male individuals of 25-40 years residing at the bhuwana village. Reason behind selection of this age group was to exclude effect of normal ageing process on lipid profile as well as blood glucose level since effect of diet on these parameters is chronic. Prior approval from the institute ethical committee was taken. Out of 100, 55 subjects were strict vegetarian while 45 subjects eat different varieties of non vegetarian food that includes egg, meat (red +white) and fish. Frequency of eating non vegetarian food was at least 3 days in week. Socio economic class of all subjects was lower middle according to Kupuswamy classification.[9] As composition and quality of diet may change in different socio economic group, subjects were selected from same locality and socio economic class. All selected subjects were skilled workers who were engaged in mild-moderate type of physical activity (metabolic equivalent task-MET <6) and neither exposed to regular exercise nor regular fast food eater. Preferred method of cooking was fry with use of soyabean oil as it is cheaper and easily available in study area. The subjects were selected by simple random sampling. Subjects with family history of diabetes, hypertension or cardiovascular event, personal history of any chronic disease like diabetes, hypertension or any autoimmune disease, addiction of alcohol, tobacco, smoking, people taking steroidal drugs, people who were acutely ill were excluded from the study.

The data was collected by means of a personal interview and history taking. All the subjects were asked to fill a Performa containing details regarding demographic profile, medical, family, personal, diet history. In diet history whether they are vegetarian or non-vegetarian, type of food intake, food with addition of sugar/ 'gud' to 'dal' and vegetables, addition of oil in making dough, type of oil used in cooking, quantity of oil/ghee and sugar/ 'gud' consumed in the household per month per person, frequency of eating out, frequency and quantity of having sweets and fried food/ snacks/ junk food, frequency and quantity of fruit and vegetable intake, frequency and quantity of dairy products like cheese, paneer and milk made items were also considered.

After personal interview physical examination including height, weight, hip and waist circumference, blood pressure measurement was conducted.

Lipid profile of each subject measured in early morning after overnight fast by portable LipidPlus machine (JantPharmacal Corporation, Encino CA). Blood glucose level was recorded by glucometer (Accu-chek active glucometer). An informed consent of all the participants was taken prior to commencing the study.

We considered following normal range of values for the various parameters.

Lipid profile: Total cholesterol (TC) 150-200 mg/dl, Low Density Lipoprotein (LDL) fraction 80-150 mg/dl, High Density Lipoprotein (HDL) fraction 30-

60 mg/dl, Fasting Serum Triglyceride (TG) 75-150 mg/dl[10].

Blood pressure: systolic blood pressure (SBP) ≥140 mmHg and / or diastolic blood pressure (DBP) ≥90 mmHg taken as hypertensive. Rest all were taken as Non hypertensive (pre hypertensive and normotensive). (JNC 7 report on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure, U. S. Department of Health and Human Services) [11].

Body mass index (BMI): BMI ≥ 30 kg/m² were classified as being Obese and those with BMI ≥25 kg/m² but <30 kg/m² were identified as being Overweight (Global database on BMI, WHO 2005) [12].

Waist Hip Ratio (WHR): a WHR > 1.0 in males was taken as abnormal (Waist Circumference and Waist–Hip Ratio: Report of WHO Expert Consultation 2008) [13].

Fasting blood glucose: <100mg/dl- normal, 100-125mg/dl- prediabetes, >125-diabetes (American diabetes association) [14].

Statistical analysis:

The data was analyzed using Microsoft excel by applying unpaired t-test for quantitative data and using Epi Info 7 version 7.0-8.3. Significance level was taken as $p < 0.05$.

Result:

Table1: Baseline characteristics of Vegetarian and Non vegetarian subjects.

	Vegetarian (Mean ±SD)N=55	**Non vegetarian* (Mean ± SD)N=45**
Age(years)	35.41± 4.49	34.55±4.09

**P<0.05

Discussion: The present study is a cross sectional study of people aged 25-40 years residing in the bhuwana village. The aim of the study was to assess effect of vegetarian and non vegetarian diet on lipid profile and blood sugar level and to know which type of diet is better than another. As per table 1 both groups are comparable for most of the baseline characteristics (p>0.05) except height, pulse rate and average intake of sugar. All three parameters were higher among vegetarians as compared to non vegetarians (p<0.05). BMI of both the groups fall under overweight category. Blood pressure is comparable in both groups which are in contrast to result of Yokoyama et al[15] and Ophir et al[16] in which vegetarians exhibit lower BP than non vegetarians. Approximate total calorie intake per person and consumption of cooking oil /person/month were within normal range and groups do not show any significant difference. Soyabean oil is very popular for cooking in this part of India.

Average per capita sugar consumption among vegetarians is significantly high (table 1) as compare to non vegetarians however it is within normal range of 35mg/day as suggested by American diabetes association[17]. Excess sugar intake can cause cardiovascular disease. Jean welsh et al[18] found that people who consumed increased amount of added sugar had increased blood levels of harmful fats. LDL and TG were increased while HDL was decreased.In our study mean fasting blood glucose level among the study groups was within normal range.

Mean total cholesterol, LDL, LDL/HDL ratio, and total cholesterol/HDL in non vegetarian subjects are 210.60mg/dl, 127.56mg.dl, 3.14 and 5.13 respectively, which is higher than mean value of 171.94mg/dl, 104.46mg/dl, 2.49 and 4.05 respectively in vegetarian group ($p<0.05$)

While mean serum triglyceride and HDL is found to be higher in vegetarian subjects which is 135.06mg/dl and 43.47mg/dl, as compared to non vegetarian subjects having mean value of 112.75mg/dl and 41.63mg/dl respectively($p<0.05$).

Result of this study matches with study done by Alexander et al[19] and Li et al[20] indicated that meat-eaters had a significantly higher cluster of cardiovascular risk factors compared with vegetarians, including increased body mass index, waist to hip ratio, plasma total cholesterol, triacyglycerol, LDL levels, ratio of TC/HDL and LDL/HDL, though in our study serum triglyceride is found to be more in vegetarians. It is a well known fact that a high consumption of plant based foods such as fruit and vegetables, nuts and whole grains reduces risk of coronary artery disease and stroke. This vegetarian diet provides protection because of mono and polyunsaturated fatty acids, n-3 fatty acids, antioxidant vitamins, minerals, phytochemicals, fibre and plant protein[21, 22].

Among non vegetarian subjects, various pattern of consumption of non vegetarian food is seen (table 3). These are egg only, meat (red +white) only, egg and meat, fish and meat, egg and fish and all three. Significant difference ($P<0.05$) in blood lipid profile is seen in subjects consuming only meat with total cholesterol and LDL 224.79mg/dl and 136.85mg/dl respectively as compared to consumers of fish and egg with total cholesterol and LDL are 169.39mg/dl and 101.71mg/dl respectively (table 4). Also HDL is higher in fish and egg eaters with 43.20mg/dl as compared to only meat eaters 40.28mg/dl. Research worldwide has indicated that eating fish regularly- one or two servings weekly is beneficial. Fish is low in fat; high in protein and an excellent source of omega 3 fatty acids which reduces incidence of heart disease[23]. We couldn't find an exclusive fish eater since study area is far away from costal line, it was difficult to define lipid profile among exclusive fish eaters. Higher values also found in consumers of egg only with total cholesterol and LDL is 200.15mg/dl and 127.56mg/dl respectively.

Conclusion

Total cholesterol and low density lipoprotein found higher among non vegetarians while high density lipoprotein and triglycerides elevated among vegetarians. Non vegetarian subjects should limit the intake of meat. Fasting blood glucose and blood pressure were within normal range.

ABSTRACT

Background: Hypertension (HT) posing a major public health challenge to the universe in socioeconomic and epidemiological transition. Hyperuricemia in HT is coupled with augmented cardiovascular morbidity and mortality. It also predates the development of HT and suggests that it is not simply a consequence of HT *per se*. Increased urate level along with greater production of oxygen-free radical and augmented oxidative stress may contribute to progression of HT. **Aims and Objectives:** This study aims to assess the correlation between serum uric acid (SUA), serum malondialdehyde (S. MDA) level, and blood pressure in early essential HT. **Materials and Methods:** In this cross-sectional study, after applying inclusion and exclusion criteria, 200 subjects were divided into three groups: 50 subjects as control group, 75 in prehypertensive group, and 75 in hypertensive group. SUA and S. MDA level were estimated in all subjects. Data were analyzed by appropriate statistical methods. **Results:** A significant and positive correlation was observed between SUA and S. MDA level in HT group. Both parameters were correlated positively and significantly with systolic blood pressure (SBP), but not with diastolic blood pressure (DBP) in hypertensive individuals. **Conclusion:** An elevated SUA level is predictive for the evolution of both HT and coronary artery disease. Hyperuricemia plays a role in the formation of free radicals and oxidative stress through increased lipid oxidation. Furthermore, positive correlation with SBP further established its potential role in the etiopathogenesis of essential HT.

KEY WORDS: Essential Hypertension; Hyperuricemia; Serum Malondialdehyde Level; Lipid Peroxidation; Oxidative Stress

INTRODUCTION

Essential hypertension (HT) is being increasingly documented as a part of a complex multifaceted disorder worldwide due to its high incidence and associated risks of renal and cardiovascular disease (CVD), for instance, stroke, myocardial infarction, and heart failure. The effective union between HT and hyperuricemia has been documented for more than a century. Studies from the 1950s and 1960s demonstrated the incidence of hyperuricemia in hypertensive cases to be between 20 and 40%.[1] Later on, it was found that an increasing level of serum urate is an autonomous risk factor of HT.[2]

DOI: 10.5455/njppp.2019.9.0727520082019	

Raised serum uric acid (SUA) level is also associated with increased cardiovascular morbidity and mortality rate.[3] Its level is thoroughly controlled by the balance among uric acid production and excretion.[4] Urate is freely filtered in the glomerulus, reabsorbed, secreted, and then again reabsorbed in the proximal tubule. Essential HT may also be linked with hyperuricemia with normal renal functions.[5] Hyperuricemia (>5.5 mg/dl [330 μmol/L]) was detected in almost 90% of teenagers with primary HT, whereas uric acid levels were

significantly lower in controls and youth with any white coat or secondary HT.[6] The finding that uric acid levels were not lifted in secondary HT also cuts down the probability that the hyperuricemia resultants from HT.

There are abundant reports that oxidative stress is amplified in patients with HT. Further, the extreme production of reactive oxygen species (ROS) due to raised urate level, out stripping antioxidant defense mechanisms, has been involved in pathophysiological conditions that influence on the cardiovascular system.[7] Moreover, ROS react with membrane lipids to yield lipid hydroperoxide, a destructive process known as lipid peroxidation. Lipid hydroperoxide decomposes to build various products containing malondialdehyde. In the present study, serum malondialdehyde (S. MDA) was used as a biochemical marker for the assessment of lipid peroxidation.

The significance of both SUA and S. MDA level in the development of essential HT has not been thoroughly investigated, especially in Southern Rajasthan. Hence, this study has been designed to study the correlation between SUA, S. MDA level, and blood pressure among newly diagnosed essential HT.

MATERIALS AND METHODS

This cross-sectional case–control study was conducted among 200 subjects in the Department of Physiology, Geetanjali Medical College and Hospital (GMCH), Udaipur. All the subjects were chosen randomly from medicine outpatient department, family members or attendants of established hypertensive patients, individual's comings to hospital for health checkup, and healthy volunteers such as clinical and non-clinical staff of a tertiary care hospital. This study was ethically approved by the institutional ethical committee of GMCH, Udaipur (Ref. No. GU/UCE/EC/2013/299 dated15/05/2013).

Inclusion Criteria

All the sex-matched subjects, aged between 20 and 50 years old were broadly divided into three groups:

- 50 participants with normal blood pressure (systolic blood pressure [SBP] = 90–119 mmHg and diastolic blood pressure [DBP] = 60–79 mmHg) were taken as control group
- 75 cases of prehypertension (preHT) (SBP = 120–139 mmHg and DBP = 80–89 mmHg) were taken as preHT group
- 75 cases of newly diagnosed cases of essential HT (SBP = 140–159 mmHg and DBP = 90–99 mmHg) were taken as HT group.

Exclusion Criteria

The subjects suffering with gout, diabetes mellitus, gestational HT, and/or secondary HT caused by renal disorders, metabolic disorders, fluid volume disturbances, endocrinal disorders, etc., were excluded from the study groups. Smokers, alcohol consumers, and patients on medication for HT were also excluded from the study. After diagnosis, a written informed voluntary consent was taken from all the participants after explaining their participation in the study in their local language. All the data from three groups were collected in the detailed pro forma along with required physical examination. For biochemical analysis, blood sample (5 ml) was drawn after an overnight fasting (12 h) by venous puncture and serum was separated by centrifugation at 3000 rpm for 10 min. SUA level and S. MDA were estimated using commercially available reagents or kits.[8,9]

Statistical Analysis

The data were analyzed using the Statistical Package for the Social Sciences (SPSS) version 16. Significance testing of difference for mean of three groups was done by analysis of variance test (ANOVA). $P < 0.05$ was used to establish statistical significance. The correlation between different parameters was assessed by Pearson coefficient of correlation test.

RESULTS

Figures 1 and 2 showing that the difference in mean of SUA level and S. MDA level between control, preHT, and HT group was highly significant ($P < 0.0001$). Table 1 shows that SUA level was significantly and positively correlated with SBP

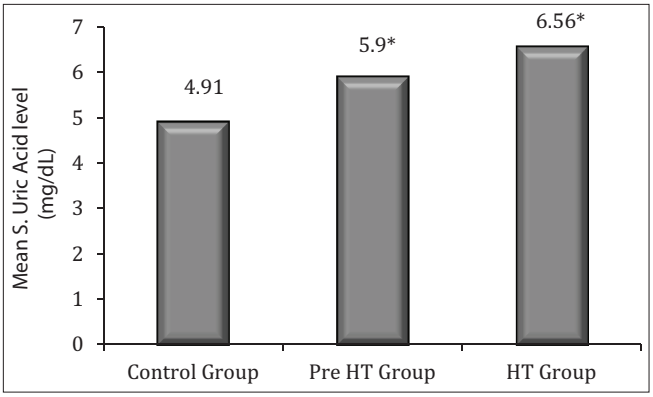

Figure 1: Comparison of mean serum uric acid level among different groups (*significant with $P < 0.001$)

Table 1: Correlation of serum uric acid levels with various parameters

Parameters	Control group		Hypertension group	
	r value	*P* value	*r* value	*P* value
SBP	−0.234	NS	+0.478	<0.001
DBP	−0.230	NS	+0.202	NS
S. MDA	+0.236	NS	+0.574	<0.001

S. MDA: Serum malondialdehyde, SBP: Systolic blood pressure, DBP: Diastolic blood pressure

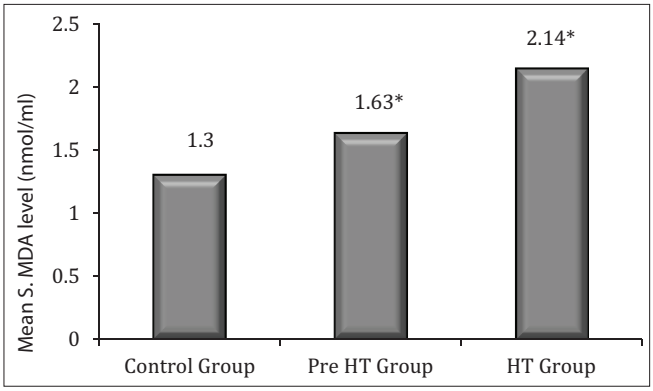

Figure 2: Comparison of mean serum malondialdehyde level among different groups (*significant with $P < 0.001$)

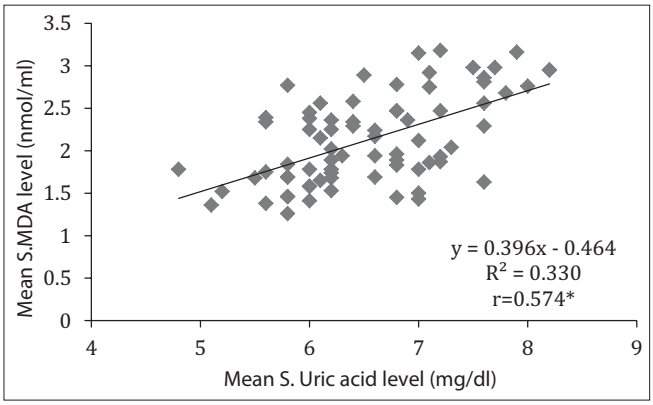

Figure 3: Correlation between serum uric acid levels and serum malondialdehyde levels (*significant with $P < 0.001$)

(r = +0.478, $P < 0.001$) and S. MDA (r = +0.574, $P < 0.001$), whereas no significant correlation was found with DBP ($P > 0.05$). Figures 3-5 showed that S. MDA was significantly and positively correlated with SBP (r = +0.486, $P < 0.001$) and SUA (r = +0.574, $P < 0.001$), whereas no significant correlation was found between S. MDA and DBP ($P > 0.05$).

DISCUSSION

In this study, we found that the mean of SUA level and S. MDA level in hypertensive group was significantly higher as compared to prehypertensive and controls ($P < 0.001$). The increased trend in mean SUA level was observed from control to prehypertensive and prehypertensive to hypertensive cases [Figures 1 and 2]. Results also showed that SUA and S. MDA were significantly and positively correlated with each other and SBP ($P < 0.001$), whereas no significant correlation was observed with DBP ($P > 0.05$) for the same.

Masuo *et al*. assessed the linear relationship of SUA and SBP and showed an average raise of 23 mmHg per 1 mg/dl increase in SUA within non-obese young men.[10] Another study on 125 children (age group 6–18 years) with essential HT proved the association of SUA with SBP (r = 0.80) and DBP (r = 0.66).[6] In support to our study, Acharya and Mishra found that S. MDA level was significantly and positively correlated

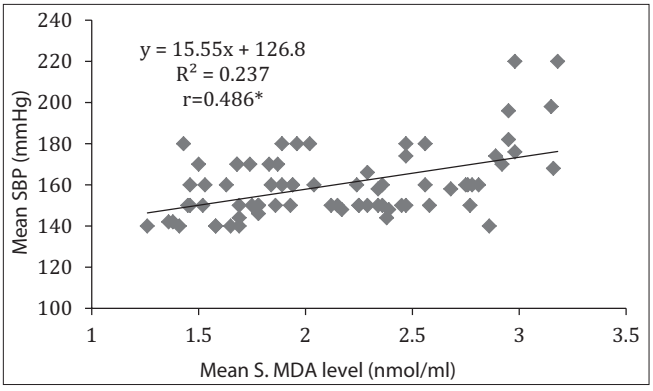

Figure 4: Correlation between serum malondialdehyde levels and systolic blood pressure (*significant with $P < 0.001$)

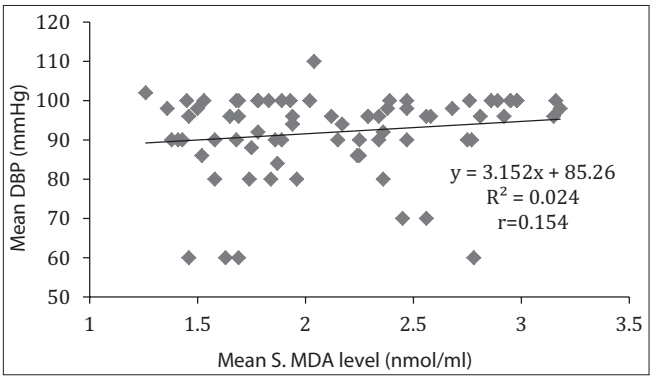

Figure 5: Correlation between serum malondialdehyde levels and diastolic blood pressure (*significant with $P < 0.001$)

with SBP (r = +0.364, $P < 0.01$) and SUA level (r = +0.289, $P < 0.05$). They found no significant correlation between S. MDA and DBP.[11] Amirkhizi *et al*. assessed the oxidative stress marker related to atherosclerosis in prehypertensive women. Regarding MDA level, they attained that MDA was positively correlated with both SBP (r = +0.24, $P < 0.001$) and DBP (r = +0.18, $P < 0.001$).[12] Ouppatham *et al*. examined the relationship of hyperuricemia and blood pressure in the Thai army population and observed a significant and positive correlation between both SUA levels and SBP (r = 0.186, $P < 0.001$) and same with DBP (r = 0.255, $P < 0.001$).[13] However, Teng *et al*. described a contrary result, wherein uric acid was associated with the risk of HT in the elderly.[14]

Hyperuricemia is commonly experienced with essential HT, even untreated HT. Studies in animal models proposed that hyperuricemia may be predominantly important in early HT[15] and likewise studies in humans illustrated that the strongest relationship of hyperuricemia is with premature HT such as discovered in adolescents.[6] Contrary to these findings, a number of studies have recommended that the association between elevated SUA and cardiovascular risk does not carry on after rectifying for other risk factors.

Experimental studies provide a credible physiologic mechanism by which increases in SUA might cause HT. Uric acid enters vascular smooth muscle cells, where it stimulates

mitogen-activated protein kinases, cyclooxygenase-2, and platelet-derived growth factor to stimulate vascular smooth muscle proliferation and preglomerular arteriolopathy.[15,16] Increased SUA further causes an increase in juxtaglomerular renin production and a decrease in macula densa neuronal nitric oxide (NO) synthase expression, leading to renal vasoconstriction and probably increasing blood pressure.[17] If renal vasoconstriction persistent, it may impart to arteriosclerosis and the exploitation of salt-sensitive HT, even if the hyperuricemia is rectified.

In addition, SUA plays a role in the formation of free radicals and may elucidate the link between hyperuricemia and HT.[18] Augmented intracellular uric acid may accelerate oxidative stress directly by raising NADPH oxidase linked ROS or generated by stimulation of xanthine oxidase during the generation of uric acid as well. Oxidative stress may contribute to the generation and/or development of HT through a number of probable mechanisms included (a) curbing of the vasodilator NO by ROS such as superoxide, (b) production of vasoconstrictor lipid peroxidation products, (c) diminution of tetra hydrobiopterin (BH4), an important NO synthase cofactor, (d) structural and functional changes within the vasculature.[19]

Experimentally, by means of which, hyperuricemia results in HT are by way of oxidative stress, endothelial dysfunction, and activation of the renin angiotensin system. The net effect is to provoke renal and systemic vasoconstriction and the progression of HT. Increase in SUA has been demonstrated as an earlier marker of HT, which occurs even before the modification in serum creatinine.[18]

Limitations

As the present study is hospital-based case–control study, so to establish these results to the population of Southern Rajasthan, large sample size should be taken.

CONCLUSION

From the above discussion, it can be concluded that increased serum MDA in hypertensive indicates an association between increased oxidative stress and HT. SUA through lipid peroxidation might be processing toward the etiopathogenesis of essential HT even in its former stages, and its serum level may be a modifiable factor for progression of the disease. Measuring these biomarkers in clinical practice may identify high-risk individuals. Further, the maintenance of the oxidative balance and SUA in hypertensive patients would be helpful in preventing the CVD and other diseases associated with HT.

Effect of Treadmill Exercise on Blood Glucose Control in Type-2 Diabetes Mellitus Patients

Paras Arvindbhai Parekh

Assistant Professor, Department of Physiology, Ananta Institute of Medical Sciences and Research Center, Rajasthan

Abstract

Background: Diabetes mellitus type 2 is because of resistance to insulin resulting in inability to utilize glucose. In addition to medicines and diet control, regular exercise helps in increase in utilization of glucose.

Aims & Objectives: To study efficacy of exercise especially treadmill walking on controlling blood glucose homeostasis in diabetes mellitus.

Material and Method: The study was conducted on 40 clinically confirmed cases of type-2 diabetes mellitus male patients who were divided in study group and control group with 20 patients in each group. Study was conducted for period of 8 weeks. Diet plan was formed by expert during this period and subjects were instructed to follow it strictly. Fasting blood glucose and postprandial blood glucose was measured before and after exercise programme.

Findings: There is significant decrease in fasting blood glucose and Postprandial blood glucose level in study group as compared to control group with inter-group difference was significant ($P<0.05$).

Conclusion: Treadmill exercise is very useful for blood glucose control in addition to diet control and medicines.

Keywords: *Type-2 diabetes mellitus, Treadmill exercise, Fasting blood glucose, Postprandial blood glucose, Glycemic control.*

Introduction

Diabetes mellitus (DM) refers to a group of common metabolic disorders that share the phenotype of hyperglycemia. The two broad categories of DM are designated type 1 and type 2. Both types of diabetes are preceded by a phase of abnormal glucose homeostasis as the pathogenic processes progress. Type 1 DM is the result of complete or near-total insulin deficiency. Type 2 DM is a heterogeneous group of disorders characterized by variable degrees of insulin resistance, impaired insulin secretion, and increased glucose production.[1]

The prevalence of diabetes is going to double globally from 171 million in 2000 to 366 million in 2030 with maximum increase in India. By 2030, around 79.4 million people will be affected by diabetes according to prediction made by Wild et al.[2]

In addition to medication and diet control, exercise is also helpful in increasing insulin sensitivity. American diabetes association recommends moderate aerobic physical activity of 150 minutes/week.[3] Walking is considered to be the best exercise as it involves larger muscles of lower limb as well as muscular work of upper limb. Treadmill machine which is electronically driven or manual simulates all the features of natural walking.

Material & Method

In our study we used treadmill (Phillips, Novafit turbo) machine, oscilloscope for measuring heart rate and respiratory rate, Sphygmomanometer for measuring

blood pressure, weighing scale. Permission from institutional ethical committee was taken.

From diabetes OPD 40 male patients of age group 45-55 years who were clinically and biochemically confirmed cases of diabetes included in study after obtaining informed consent. Patients with known case of cardiac, respiratory, renal and musculoskeletal disorders were excluded from programme. Those who were willing to do exercise were included in study group and who were not willing to do exercise were included in control group.

Whole programme was conducted for period of 8 weeks. At the beginning of study, fasting blood sugar (FBS) and postprandial blood sugar (PPBS) was measured for all subjects. Additionally weight, height and body mass index was measured. Subjects were examined for any muscular weakness in lower limb. Regular diet may vary in different subjects so diet plan was formed for whole day by advice of dietician and they were explained to follow it strictly during the whole exercise programme so as to avoid effects of diet on blood glucose level.

Treadmill machine (Phillips, Novafit turbo) used for the study can measure speed in form of RPM, total distance travelled in kilometers and calories used during exercise. All subjects in study group were first given demonstration of treadmill machine to make them familiarize. Programme was conducted for total 40 minutes which include 5 minutes of warm up, 30 minutes of treadmill walking followed by 5 minutes of rest. All subjects were instructed to report immediately if they feel breathlessness, headache, dizziness or any other symptoms which are indicative for stopping exercise. Blood pressure, heart rate and respiratory rate were taken in supine at the beginning of exercise.

First warm up was done in the form of active limb movements and muscle stretching. Then oscilloscope was attached for monitoring of heart rate, respiratory rate and blood pressure. Subjects were instructed to walk on treadmill for 30 minutes. Speed of treadmill machine was set to 3.5 km/hour with fixed inclination. All the subjects were constantly monitored for development of any symptoms and any noticeable change in parameters. At the end of thirty minutes, parameters were measured immediately and then they are instructed to take rest for five minutes. Vital parameters were also taken during recovery period of five minutes. This completed session was conducted for five days in a week for total 8 weeks. At the end of 8 weeks FBS and PPBS was taken again for both groups. Statistical analysis was done using student's t test with p value < 0.05 is considered as statistically significant.

Findings

All the subjects in study group completed exercise programme without any event. Pre and post exercise blood glucose levels are compared in both study and control group.

In study group, FBS and PPBS level before exercise was in the range of 150-196 mg% and 180-212 mg% respectively. After exercise programme range of FBS and PPBS was 130-162 mg% and 156-170 mg% respectively.

In control group, FBS and PPBS level before exercise was in the range of 154-202 mg% and 184-210 mg% respectively. After 8 weeks of observation range of FBS and PPBS was 150-188 mg% and 168-200 mg% respectively.

Difference between FBS and PPBS before and after programme in both the group was compared (Table-1). Mean decrease in FBS in study group was 38.6 mg% while in control group it was 26.8 mg% with intergroup difference is statistically significant ($p<0.05$). In study group decrease in PPBS was 42.8mg% as compared to control group having difference of 30.4 mg%. So inter group difference in PPBS is statistically significant (p value <0.05). Also subjects in study group reported of feeling of well being with loss of average two kilograms weight.

Table-1 Comparison between study and control group for change in FBS and PPBS after programme

Difference	Study group (mean±SD) Control group (mean±SD) n=10
FBS1-FBS2	38 ± 8.275 26 ± 8.910*
PPBS1-PPBS2	42 ± 6.784 30 ± 8.623*
FBS1- Fasting blood glucose before exercise FBS2- Fasting blood glucose after exercise PPBS1- Postprandial blood glucose before exercise PPBS2- Postprandial blood glucose after exercise *p<0.05, student t-test	

Discussion

Diabetes Mellitus is a clinical syndrome comprising a heterogeneous group of metabolic diseases that are characterized by chronic hyperglycemia and disturbances in carbohydrate, fat and protein metabolism secondary to defects in insulin secretion, insulin action or both.[4] Comprehensive management of diabetes includes drugs, insulin, lifestyle changes comprising of diet control, exercise and education.[5] In this study, efficacy of treadmill exercise on control of blood glucose was studied in addition to diet control and medication. Exercise improves insulin sensitivity and therefore has a positive effect on blood glucose control. In addition it also has positive effects on lipid profile and blood pressure and it is important part of weight management programme. For inactive person it is better to start with at least 5 minutes daily and then gradually increase 5 minutes to up to at least 30 minutes of daily walking.[6] Only problem with diet and exercise is that it requires strong motivation and self confidence. So for the patient's perspective oral drugs for diabetes is the best management.

At the beginning of exercise, muscle utilizes stored glycogen as fuel consumption. But it is available only for short period only. If activity is continued, glycogenolysis becomes source of glucose and then after few minutes gluconeogenesis starts in liver. After depletion of glycogen store in liver, stored fat in adipose tissue converted into fatty acids which are used as fuel by muscle.[7]

Wahren et al. reported that working muscles are more sensitive to insulin as compared to resting muscle, which increase utilization of glucose. Also during exercise blood flow to working muscle increase which increase size of capillaries and number of insulin receptors which ultimately balance sensitivity of insulin.[8]

Shivananda nayak et al. reported that after six weeks of treadmill exercise, glucose utilization is increased in muscle which has positive effects on glucose homeostasis with significant fall in fasting and postprandial blood glucose level.[9]

Exercise programme is also affected by some factors like type of exercise, duration of exercise, intensity and frequency of exercise. According to American college of sports medicine, exercise with low intensity but long duration gives better result as compared to high intensity short duration exercise. Duration of exercise should be gradually increased over days. Exercise programme should be restricted to five days per week. Intensity can be controlled by counting target heart rate with formula of subtracting your age from 220. In this study it was found that endurance exercise helps in control of blood glucose level. It works by increasing insulin sensitivity in exercising muscle. As compared to resting condition, numbers of insulin receptors are more in working muscle which ultimately helps to utilize glucose despite low production by pancreas as in diabetes mellitus.

Conclusion

Well planned exercise programme which is strictly followed can improve glycemic control and also helps to reduce weight. In addition to mental well being it reduces cardiovascular risk factors in patients of diabetes mellitus.

Abstract

Context: Alcohol consumption has been steadily increasing all over world, especially in India. Alcohol can cause physical, mental and social effects which is determined by quantity and pattern of alcohol drinking.

Aim: Present study was conducted to observe alterations in the biochemical and haematological parameters in heavy alcohol consumers.

Subjects and Method: 40 young males of 20-40 years age with history of daily alcohol consumption for past one to five years duration were included in study .Estimation of the biochemical and haematological parameters were carried out in study and control subjects**.**

Statistical Analysis: Analysis of the haematological and biochemical parameters data of the study subjects and controls was done by using student t test

Results: Lipid profile parameters were not altered in study subjects .Liver enzymes AST and ALT were significantly elevated in alcoholic subjects. Hemoglobin and platelets was lower in alcoholic subjects. Mean corpuscular volume was significantly higher in alcoholics.

Conclusion: These alterations of liver enzymes and haematological parameters in alcoholics can be used as early indicator of alcohol abuse and person can be motivated to stop alcohol consumption.

Key words: Alcoholics, Lipid profile, Liver enzymes, Hemoglobin

Introduction

Alcohol is not often thought as a drug largely because its use is common for both religious and social purposes in most parts of world. However , it is a drug and of all the drugs , alcohol is the only drug whose self induced intoxication is socially acceptable. Compulsive drinking in excess has become modern society's one of the most serious problems [1] . Alcohol has been widely consumed through ages because of its perceived benefits as a social lubricant and for relaxation , mood alteration and sensory pleasure . But long term consumption of large amount is harmful leading to addiction and fatal or non fatal injuries . Alcoholism is a worldwide social and medical problem . Over the past 30-40 years , alcohol consumption has increased in quantity and frequency [2] . The age at which people start drinking has also declined. Consumption of alcohol in young people has created concern as alcoholism may run a greater risk of alcoholic problems in later life [3] .All organs can be damaged due to direct effects of alcohol, especially the digestive and nervous systems . At the level of

digestive system , alcohol causes gastrointestinal problems , cirrhosis of liver , pancreatitis and cancer of mouth , pharynx and oesophagus . At level of nervous system it causes problems with reflexes , vision , equilibrium of the body , lesions of nerves [4] . Alcohol has numerous adverse effects on various types of blood cells and their functions [5]. Other effects include loss of appetite, vitamin deficiency , infection , sexual impotence and menstrual irregularities. The diagnosis occurs when the adverse effects are already obvious and recognizable[6]. Effective and low cost methods are now available for identification and treatment of alcohol addiction at an early stage . They include various haematological and biochemical parameters. Some of the commonly studies parameters are Aspartate amino transferase (AST), Alanine amino transferase (ALT) , Alkaline Phosphatase, and haemoglobin (Hb%) , Mean corpuscular volume (MCV) , Mean corpuscular Haemoglobin (MCH) . Combination of one or more of these markers has been reported to give better sensitivity and diagnostic accuracy characterizing the early events leading to alcoholic disease at later stage. Earlier studies have shown the once the alcohol consumption is stopped at earlier stage, the alteration are reversed, thus altering the pathway of morbidity and mortality and ensure a disease free life to the individual.

The present study was done to identify the alteration in serum lipid profile, liver enzymes (AST, ALT) and haematological parameters like haemoglobin (Hb%) Mean corpuscular volume (MCV) , Mean corpuscular Haemoglobin (MCH) , platelet counts in asymptomatic young alcoholic individuals of 20-40 years age group, which were considered as a heavy drinkers with history of consumption of alcohol for one to five years.

Material and methods:

This case control study was conducted in November 2019 to February 2020 . The study was done by obtaining blood and serum samples from study and control subjects . The samples were drawn in morning under aseptic precautions after over night fast . The study group consisted of 40 subjects and 40 control subjects . They were selected on the basis of following inclusion and exclusion criteria.

Inclusion criteria:

Male subjects aged 20-40 years with history of heavy alcohol consumption for duration of one to five years .

Exclusion criteria :

Person with following disorders were not included in study.

- Hypertension
- Diabetes mellitus
- Malignant condition
- Cardiovascular and respiratory disorders
- Individual on medication
- Smokers

Collection of blood samples , which is invasive procedure and need overnight fasting was explained to the subjects in detail. Subjects unconditionally gave consent to participate in study. The study complied with the Declaration of Helsinki and protocol was approved by the institution review board.

Method of collection of data.

- A questionnaire was given to the subjects and controls to elicit the details of alcohol consumption , history of past or present illness [7] .

- The average number of alcohol drinks consumed per mouth was asked .Daily consumption of six or more drinks (> 90 ml daily) was defined as heavy drinker [8] .
- Height and weight was recorded . Body mass index was calculated.
- Vital parameters like pulse rate , Blood pressure was recorded .Detail examination of cardiovascular , Respiratory system , Abdomen and Central nervous system was done.
- Under aseptic precautions 4 ml of blood was drawn from anterior cubital vein .2ml was taken in EDTA bulb for estimation of Haematological parameters and 2 ml was taken in a plain bulb for estimation of lipid profile and liver enzymes in blood .
- Serum lipid profile and liver enzymes were estimated by using Biochemistry Analyzer.
- Haematological parameters were measured by using Automated hematology Analyzer.
- Following parameters were studied .

1) Lipid profile - Total cholesterol (TC) ,High density lipoprotein cholesterol (HDL-C) ,low density lipoprotein cholesterol (LDL-C) , Very low density lipoprotein cholesterol (VLDL-C), and Triglycerides TL.
2) Liver enzymes - Aspartate amino transferase (AST) , Alanine amino transferase (ALT) , Alkaline Phosphatase .
3) Haematological parameters like haemoglobin (Hb %) , Mean corpuscular volume (MCV) , Mean corpuscular Haemoglobin (MCH) , platelet counts

Statistical Analysis :

Analysis of the haematological and biochemical parameters data of the study subjects and controls was done by using student t test [9,10] . p value was calculated , $p < 0.05$ was considered significant and $p < 0.01$ was considered highly significant , > 0.05 was considered not significant .

Results :

The results obtained were expressed as Mean ± Standard deviation . p value was calculated

Anthropometric data

The table 1 shows anthropometric data of the study subjects and controls . There was no significant difference in Age , Weight , Height , BMI between study and control groups.

Table 1 : Anthropometric data of control and study subjects .

Anthropometric Parameters	Control subjects Mean ± SD (n = 40)	Study subjects Mean ± SD n = 40	P value	Significance
Age (Years)	30.8 ± 2.8	31.48 ± 3.22	> 0.05	Not Significant
Weight (Kg)	60 ± 7.23	63.36 ± 4.24	> 0.05	Not Significant
Height (Cm)	165.3 ± 7.2	163.4 ± 5.82	> 0.05	Not Significant
BMI (Kg/ m^2)	22.82 ± 2.54	23.24 ± 2.24	> 0.05	Not Significant

Vital data

Resting pulse rate :

The Mean ± SD of pulse rate at rest in control was 76.24 ± 3.26 beats / minute and in study subject was 72 ± 4.32 beats / minute .There was no significant difference in the resting pulse rate between the two groups.

Blood Pressure :

The Mean ± SD systolic blood pressure at rest in controls was 122.24 ± 4.26 mm Hg and 124.42 ± 6.18 mm Hg in study subjects .

The Mean ± SD diastolic blood pressure was 78.62 ± 4.24 mm Hg in control and 76.34 ±3.82 mm Hg in study subjects.
There was no significant difference in Blood Pressure between study and control group.

Lipid Profile :

The lipid profile data of study and controls are shown in Table 2.

Table 2: Lipid profile data of control and study subjects .

Parameters of Lipid Profile (mg/dl)	Control subjects Mean ± SD (n = 40)	Study subjects Mean ± SD (n = 40)	P value	Significance
Total cholesterol	210 ± 36.24	218.18 ± 32.46	> 0.05	Not Significant
HDL-cholesterol	42.46 ± 6.48	40.24 ± 8.21	> 0.05	Not Significant
LDL-cholesterol	140.18 ± 32.78	138.24 ± 30.68	> 0.05	Not Significant
VLDL-cholesterol	26.82 ± 10.26	27.76 ± 11.34	> 0.05	Not Significant
Triglycerides	148.72 ± 48.26	150.36 ± 44.34	> 0.05	Not Significant

There was no significant difference between the serum lipid profile parameters between study and control subjects.

Liver enzymes :

The data of liver enzymes of study and controls are shown in table 3.

Table 3: Liver Enzymes data of control and study subjects

Liver enzymes (IU/L)	Control subjects Mean ± SD (n = 40)	Study subjects Mean ± SD (n = 40)	P value	Significance
AST	21.38 ± 6.72	34.42 ± 7.26	<0.01	Highly Significant
ALT	16.84 ± 8.03	25.76 ± 9.34	<0.05	Significant
Alkaline Phosphatase	62.76 ± 11.42	60.82 ± 9.34	>0.05	Not Significant

AST levels were more in alcoholic subjects as compared to control subjects and this difference was statistically highly significant .
ALT levels were significantly higher in alcoholic subjects as compared to control group subjects.
There was no significant difference in alkaline phosphatase levels between the two groups.

Haematological parameters :

Table 4: Haematological parameters of study and controls .

Haematological parameters	Control subjects Mean ± SD (n = 40)	Study subjects Mean ± SD (n = 40)	P value	Significance
Haemoglobin (gm/ dl)	13.64 ± 1.24	11.34 ± 1.05	<0.05	Significant
Mean corpuscular volume(fL)	84.76 ± 5.37	92.84 ± 6.24	<0.01	Highly Significant
Mean corpuscular aemoglobin(pg)	31.86 ± 1.24	32.241.18	>0.05	Not Significant
Platelet count (lac /mm^3)	2.75 ± 0.67	2.01 ± 0.48	<0.01	Highly Significant

Haemoglobin was lower in study subjects .There was significant difference in haemoglobin levels in study and control group subjects .The Mean corpuscular volume of the study subjects was significantly higher as compared to controls. There was no significant difference in Mean corpuscular Haemoglobin values between two groups. Platelet count was lower in the study subjects as compared to control subjects and this difference was highly significant.

Discussion :

This study was conducted to find the effects of alcohol abuse in young adults of 20-40 years age group with history of heavy consumption of alcohol for duration of one to five years .The effects of alcohol intake on serum lipids and lipoprotein depends on the dose and mode of alcohol intake , individual susceptibility , genetic variables and dietary factors .In heavy drinkers the synthesis of VLDL is stimulated .Even short term use of alcohol stimulate lipoprotein lipase activity in adipose tissue and consequently the concentration of VLDL in plasma stays normal or is even subnormal . There is increased transport rate of VLDL particles as a result of high lipoprotein lipase activity results in upregulation of HDL receptors [11].

In our study , lipid profile parameters like Total cholesterol , HDL cholesterol LDL cholesterol and triglycerides were studied .We observed that there was no significant alteration in the lipid profile parameters between control and study subjects. This findings correlates with the previous study done by T. Oduaola et al in which there was no association between alcohol intake with total cholesterol levels [12]. Similar observation were also found in a study conducted by Marita Passilta et al in which there was no difference in HDL-C and LDL-C concentration between controls and in those with highest alcohol intake [13]. However , Vaswani . M et al in their study found values of Total cholesterol , HDL-C , VLDL-C , Triglycerides except LDL-C were higher in alcohol dependents as compared to non dependent subjects . Similarly study by John .B Whitfield et al , showed that the triglycerides levels were increased with increasing alcohol intake . Studies by J.B Ruidavets et al and Hans Hoffmeister et al , found that blood levels of HDL- C increased with increasing alcohol intake [14,15] . The above studies were conducted in people with history of longer duration of alcohol consumption of greater than 5 years , which may be reason for the alteration in lipid profile in these subjects . Our results showed no alteration in lipid profile as our subjects were exposed to shorter duration of one to five years . In our study we studied the liver enzymes like SGOT , SGPT , and alkaline phosphatase .We observed that the liver enzymes SGOT , SGPT were significantly higher in study subjects as compared to controls . Alkaline phosphatase did not alter in both groups. Osaretin Albert Taiwo Ebuehi et all in a study found the activities of SGOT , SGPT Alkaline phosphatase of heavy drinkers were higher as compared to moderate drinkers and non drinkers [16] .An association between liver disease and heavy alcohol consumption was recognised more than 200 years ago [17] . The liver is particularly susceptible to alcohol related injuries .Since liver is the major site of alcohol metabolism .Alcohol is broken down in liver and free radicals are generated .Liver injury is caused by direct toxicity of free radicals [18]. When hepatocytes are damaged , they leak enzymes in to blood .Hence level of liver enzymes in plasma is important indicator of liver dysfunction .

Various haematological parameters like Haemoglobin content , Mean corpuscular volume , Mean corpuscular haemoglobin and Platelets were studied in our study. Haemoglobin was lower in alcoholic subjects as compared to controls subjects and this difference was statistically significant. Anemia was found in a study conducted by Subir Kumar Das et al , Latvala J et al and Louis.W Sullivan et al [19,20,21] . A number of clinical observation in man have suggested that alcohol may act as a haematological toxin in body. In our study MCV was higher in study subjects as compared to controls and this was statistically highly

significant. Platelets count was lower in study subjects as compared to controls and this difference was statistically highly significant. A study conducted by John Lindenbaum et al , showed a marked decrease in platelet count in alcoholics [22]. David Savage et al found an increase of MCV and lower platelet counts much more commonly associated with heavy alcoholic intake [23] .

The adverse effects of alcohol on Haemopoietic system are both direct and indirect . Direct effect of alcohol consumption include toxic effects on bone marrow and blood cell precursors. The indirect effect include nutritional deficiencies like folic acid and other vitamin resulting in macrocyte of red blood cells .Alcohol intake can interfere with a late stage of platelet production by suppressing the maturing megakaryocytes . Alcohol also shorts the life span of existing platelets .

Conclusion :

The present study concludes that consumption of alcohol for duration of one to five years may not alter the levels of lipid parameters in body .Liver enzymes were increased in heavy drinkers as compared to non alcoholics . Anaemia is commonly observed in alcoholics. There alteration can be considered as early indicater of alcoholism . These changes are found to be reversible once alcohol consumption is stopped as observed by many researchers .Therefore awareness should be created among public regarding major health problem associated with alcohol intake .This will help to lesser the damage and better recovery of alcoholic individuals .

Change in Basal Cardiac and Respiratory Parameters after Regular Practice of Bhramari Pranayama and Yoganidra in Young Medical Students

Ritu Bajpai[1]*, Chanda Rajak[2], Sanjeev Rampalliwar[3]

[1]Assistant Professor, Department of Physiology, Ananta Institute of Medical Sciences & Research Center, Rajsamand.
[2]Professor, Department of Physiology, Shyam Shah Medical College, Rewa.

ABSTRACT

Background: *Chronic obstructive pulmonary disease (COPD) patients are prone to exacerbation that account for significant morbidity and mortality. According to physio-pathologic and clinical-functional viewpoints, bronchiectasis and COPD have some common characteristics, it has been observed that bronchiectasis was present in up to 50% of patients with moderate to severe COPD . This observation suggests that COPD is a risk factor for bronchiectasis. Previous studies support the beneficial effect of Bhramari pranayama and Yoganidra individually in hypertension and other diseases. This is a study to evaluate effect of combination of pranayama and meditation on basal cardiac and respiratory parameters in young healthy individuals.*

Aim*: The aim of this study was to investigate the effect of regular practice of Bhramari pranayama and Yoganidra for 3 months on the basal cardiac and respiratory parameters of young healthy medical students.*

Methods: *Total 94 young medical students were selected who performed Bhramari Pranayama and Yoganidra for a duration of 3 months. Basal values of pulse, blood pressure and respiratory rate were recorded on each student before and after yoga.*

Results: *In our study mean pulse rate before yoga was 76.39 ± 4.34 per min. and after yoga it reduced to 74.56 ± 3.55 per min ($p < 0.001$) .The basal systolic blood pressure before yoga was systolic 117.12 ± 4.470 mm Hg and diastolic 74.18 ± 3.884 mm Hg .After 3 months of yoga systolic reduced to 114.18 ± 4.103 mm Hg and diastolic blood pressure fell to 71.37 ± 2.570 mm Hg ($p < 0.001$). Before yoga the mean respiratory rate was 19.25 ± 1.756 per minute which reduced to 18.16 ± 1.37 per minute ($p < 0.001$).*

Conclusions*: Bhramari Pranayama and Yoganidra significantly reduced pulse, blood pressure and respiratory rate.*

Keywords: *Bhramari Pranayama, Yoganidra, Pulse, Blood pressure, Respiratory Rate*

INTRODUCTION

Yoga has been scientifically proven to be beneficial in a number of diseases till date. In modern times sedentary lifestyle and stress has increased the incidence of diseases like hypertension, diabetes etc.

Two specific techniques i.e. pranayama and Yoganidra have been individually shown to have beneficial effects on the cardiovascular and respiratory parameters.

Pranayamic breathing has been shown to contribute to a physiological response characterized by the presence of decreased oxygen consumption, decreased heart rate, and decreased blood pressure, as well as increased theta wave amplitude in EEG recordings, increased parasympathetic activity accompanied by the experience of alertness and re-invigoration.[1]

Training in yogic respiratory exercises, selectively increases the respiratory sensation, perhaps through its persistent conditioning of the breathing pattern.[2]

Also meditation & relaxation techniques like Yoganidra can also be beneficial in preventing hypertension.[3]

The practice of a combination of yoga with meditation has been shown in some studies to have profound effect on cardiac and respiratory parameters.[4] But there are very few

studies which have evaluated this combination.

Our study aimed at studying effect of a combination of a pranayama and a meditation technique viz. Bhramari Pranayama and Yoganidra on basal cardiac and respiratory parameters.

METHODS

This study was done at Department of Physiology, SSMC Rewa (Madhya Pradesh), India. 94 medical students in the age group of 17-27 years participated in the study after obtaining clearance from an ethical committee of the institute and after taking written informed consent. They did Bhramari Pranayama and Yoganidra under guidance for 3 months. Those excluded from the study were anyone having respiratory or cardiac diseases or those on medical treatment. Pulse, respiratory rate and blood pressure was measured. Statistical analysis was done by MS Excel 2010 software.

RESULTS

This study was done at Department of Physiology, SSMC Rewa (Madhya Pradesh), India. 94 medical students in the age group of 17-27 years participated in the study after obtaining clearance from an ethical committee of the institute and after taking written informed consent. They did Bhramari Pranayama and Yoganidra under guidance for 3 months. Those excluded from the study were anyone having respiratory or cardiac diseases or those on medical treatment. Pulse, respiratory rate and blood pressure was measured. Statistical analysis was done by MS Excel 2010 software.

Table : Showing comparison of Pulse & Respiratory Rate in the subjects before and after Yoga

S No	Parameters	Before Yoga		After Yoga		Difference of mean value	P value
		Mean Value	S. D.	Mean Value	S. D.		
1	**Pulse Rate** (per min.)	76.39	4.342	74.56	3.55	1.83	<0.001
2	**Respiratory Rate** (per min.)	19.25	1.756	18.16	1.37	1.09	<0.001
3	**Systolic blood pressure** (mmHg)	117.12	4.470	114.18	4.103	2.9375	<0.001
4	**Diastolic blood pressure** (mmHg)	74.18	3.884	71.37	2.570	2.8125	<0.001

Thus all the cardiac and respiratory parameters examined i.e. pulse, respiratory rate and blood pressure (systolic and diastolic) had reduced significantly with regards to the difference in their mean value before and after bhramari pranayama and Yoganidra ($p<0.001$).

DISCUSSION

It was found in our study that there was significant reduction in pulse, respiratory rate and both systolic and diastolic blood pressure after regular practice of Bhramari Pranayama and Yoganidra. It is explained increased effect of the parasympathetic system on the autonomic regulation of these parameters as illustrated in many studies.

K Upadhyay Dhungel et al reported a decrease in pulse rate after Nadisudhi Pranayama for 4 weeks in their study.[5] Varun Malhotra et al conducted a study on thirty two subjects and reported a drop in pulse rate from 71.19±6.3 to 65.88±5.6. The change being significant at $p<0.001$. Also the subjects felt joy, peace and calm at the end of the procedure.[6]

T Pramanik et al showed in their study that in both the sexes slow Bhramari pranayamic breathing (respiratory rate 3/min) for 5 minutes caused a slight fall in heart rate. In male subjects heart rate was decreased from 78 beats/min to 76 beats/min and in female volunteers the same was decreased from 82 beats/min to 79 beats/min.[7]

Pratima M. Bhutkar et al observed that resting blood pressure and pulse rate were reduced significantly after regular practice of suryanamaskar and the cause of decrease resting b.p. and pulse rate was attributed to increased vagal tone and decreased sympathetic activity.[8]

Shankarappa V et al showed that the pulmonary function test values improved after short term(6 weeks) pranayama practice.The reason given was strengthening of the respiratory muscles and improvement in the expiratory power and decreased resistance to the air flow in the lungs. Pranayama training causes an increase in the voluntary breath holding time. This may be due to acclimatization of the chemoreceptors to hypercapnoea.[9]

Upadhyay Dhungel K et al compared different cardio respiratory variables before and after four weeks of alternate nasal breathing exercises and showed a fall in systolic pressure and diastolic pressure.

Reduction in heart rate and blood pressure indicate a shift in the balancing components of autonomic nervous system towards the parasympathetic activity which was reported by Santha Joseph et al and Anand BK et al.[10]

Meditation by modifying the state of anxiety reduces stress induced sympathetic over activity thereby decreasing arterial tone and peripheral resistance, and resulting in decreased diastolic blood pressure and heart rate.[11]

The study done by us shows clearly the benefits of combination of Bhramari pranayama and meditation techniques like Yoganidra in regulating the basal cardiac and respiratory parameters which is vital in both prevention and treatment of lifestyle related diseases.

CONCLUSION

Regular practice of Bhramari Pranayama and Yoganidra is beneficial for the cardiovascular and respiratory system as it counters the ill effects of stress and sedentary lifestyle. The mortality and morbidity associated with these lifestyle diseases like hypertension can be reduced by adopting yogic practices.

Effect of Gender on Reactivity to Cold Stress in Young Medical Students

Ritu Bajpai[1*], Chanda Rajak[2]

[1]Assistant Professor, Department of Physiology, Ananta Institute of Medical Sciences & Research Center, Rajsamand.
[2]Professor, Department of Physiology, Shyam Shah Medical College, Rewa.

ABSTRACT

Background: *Previous studies have found contradictory results in reactivity pattern in males and females to cold pressor test . It is important to understand these differences and its subsequent relevance in the pathogenesis of cardiovascular diseases like hypertension and coronary artery disease.*
Aim: *The purpose of this study was to investigate the effect of gender on reactivity to cold pressor test in young healthy medical students.*
Methods: *94 young medical students in the age group of 17 to 27 years were subjected to cold pressor test and the systolic and diastolic blood pressure recorded before and after the test.*
Results: *The mean systolic rise of blood pressure was found to be 13.63 ± 9.71mm Hg in females as compared to 12.31 ± 5.79 mm Hg in males. The mean diastolic rise in blood pressure was 9.71 ± 4.58 mm Hg in females as compared to 8.84 ± 4.14 mm Hg in males. The difference of mean for both mean systolic and diastolic rise of blood pressure in male and female subjects was not found to be statistically significant (p value = >0.1). The percentage of female hyper-reactors (36%) was found to be more than male hyper-reactors (31%).*
Conclusions*: No statically significant difference was found in the reactivity to cold pressor test between males and females. The percentage of female hyper-reactors was more probably due to lower threshold to cold induced pain.*

Keywords: *Cold pressor test, gender, hypertension.*

INTRODUCTION

Hypertension and coronary artery disease have emerged as a major epidemic reinforced by the modern sedentary lifestyle and stress. The hypothalamus mediates response to stress by activating the sympathetic nervous system to release epinephrine and nor- epinephrine, leading to intense vasoconstriction and increased systemic vascular resistance. ADH and aldosterone also contribute.[1,2]

The use of cold pressor test, given by Hines and Brown, in the prediction of hypertension is well established in a number of studies.[3,4,5]

But there are few studies on gender variations in response to cold pressor test. Estrogen is known to have both good (vasodilator, increases HDL) and bad effects (increased tendency for thrombosis) on cardiovascular system. But by and large it is said to protect the cardiovascular system especially against coronary artery disease in the reproductive period.

Previous studies gave contradictory results on different response in males and females to cold pressor test. Understanding the different response to cold stress in both genders will give us an idea about the difference in pathogenesis of hypertension and coronary artery disease in males and females. Our study aimed at finding the same.

METHODS

Our study was done at Department of Physiology, SSMC Rewa (Madhya Pradesh), India. 94 medical students (Age 17-27 years) were taken as subjects in the study out of which 45 were males and 49 females. Due permission was taken from ethical committee of the institute and written informed consent taken from students. Blood pressure was measured before and after the cold pressor test. Statistics was done by MS Excel 2010 software.

RESULTS

The mean systolic rise of blood pressure on applying the cold stimulus was found to be 13.63 ± 9.71mm Hg in females as compared to 12.31 ± 5.79 mm Hg in males. The mean diastolic rise in blood pressure was 9.71 ± 4.58 mm Hg in females as compared to 8.84±4.14 mm Hg in males. The difference between mean for both mean systolic and diastolic rise of blood pressure in male and female subjects was found to be not statistically significant (p value = >0.1).

Table 1: showing comparison of cold pressor reactivity between male and female subjects

S No	Rise of BP after cold stress	Males (n=45)		Females (n=49)		Difference Of mean	P value
		Mean	S.D.	Mean	S.D.		
1	Systolic rise	12.311	5.799	13.633	9.714	1.322	>0.1
2	Diastolic rise	8.8444	4.145	9.714	4.583	0.8696	>0.1

A total of 32 students were found to be hyper-reactors out of which 18 were females and 14 were males.

Table 2: showing distribution of male & female subjects regarding reactivity to cold pressor test

Category	Number and percentage of Males (Total males = 45)	Number and percentage of Females (Total females = 49)	Number and percentage of Total Subjects (Total subjects = 94)
Hypo-reactors	31 (68%)	31 (63%)	62 (65.95%)
Hyper-reactors	14 (31%)	18 (36%)	32 (34%)

DISCUSSION

Our study found that there was no significant difference to reactivity to cold stress amongst males and females. These results were similar to Kilogaur et al who found that males and females showed similar pressor response but blood pressure in males take longer to return to baseline. The explanation given was that men respond with greater and more prolonged peripheral adjustments (e.g., rise in SVR), whereas females are more like "cardiac" responders, with greater increases in heart rate and an attenuated blood pressure response to CPT.[6]

We also found that there was greater percentage of female hyper-reactors as compared to males. This may be due to higher threshold of pain in men as found by several studies.[7-9]

Also, Pierre-Julien et al found that myocardial blood flow as measured by CMR coronary sinus flow quantification revealed a higher response of myocardial blood flow in response to cold pressor test in women than in men. The reason given was gender differences in endothelial-dependent vasodilatation.[10]

Mahalakshmamma V et al found a greater rise in systolic blood pressure in females as compared to males whereas Srivastav et al found greater pressor response in females as compared to males in both systolic and diastolic values. The probable reasons for this variation were given as presence of more estrogen in females which has vascular protective actions especially in young females.[11,12]

Mclean JK et al found reduced pressor response in females as compared to males and Rachel M et al also found similar results in addition to reduced dilatation of the common carotid artery in females as well. It was found that the the mechanisms involved did not include a parallel difference in heart rate or venous plasma nor epinephrine concentration.[13,14]

Thus, a lot of further research is warranted to understand this gender variation in response to cold stress as it gives us an idea about the different pathogenesis of disease like hypertension and coronary artery disease in both genders especially pertaining to vascular endothelial factors.

CONCLUSION

Although we did not find any significant difference in the reactivity to cold stress between males and females per say but further studies are necessary to understand the difference in response to cold pressor test in both the genders. The percentage of female hyper-reactors was more probably due to lower threshold to cold induced pain.

ABSTRACT

Background: Consuming tobacco is a major addiction worldwide. Smoking tobacco in the form of cigarette or beedi is prevalent in both males and females. Smoke of cigarette and beedi contains more than 2000 different toxic materials. These toxic materials produce local as well as systemic tissue damage. The damage caused by this smoke is mostly due to the oxidative stress produced by the free radicals due to smoking. **Aims and Objectives:** The aim of the study is to find out the level of oxidative stress in smokers and compare it with the non-smoking subjects of the same age group. Furthermore, this study aims to find out relationship of pack-years of smoking with the oxidative stress in the smokers. **Materials and Methods:** A total of 30 smokers having a history of more than 10 pack-years of smoking and 30 non-smoker subject of the age group of 40–70 years of age with no major illness were selected for the study. The serum superoxide dismutase (SOD) enzyme level was measured. The estimated SOD level was compared in both the groups. **Results:** When both the groups were compared for the serum SOD level, it was found that the SOD level was significantly low in the smokers as compared to non-smokers. Furthermore, there was a significant negative correlation between the pack-years of the smoking and the serum SOD level. **Conclusion:** The result of the study shows that smoking enhances oxidative stress by decreasing the level of lifesaving antioxidant enzymes in the body. This decrease in levels of antioxidant enzymes makes the smokers prone to various diseases such as coronary artery disease, chronic obstructive pulmonary disease, and cancers.

KEY WORDS: Smoking; Superoxide Dismutase; Oxidative Stress; Pack-years

INTRODUCTION

Tobacco is one of the most common addictions prevalent worldwide. Tobacco can be consumed in various ways. A common way to consume tobacco is by smoking cigarettes and beedies. A research showed that there are nearly 1.1 billion smokers present across the world making smoking one of the major addictions in the world.[1] Cigarette smoke contains more than 10^{10} toxic chemicals such as nicotine, ozone, benzene, phenols, carbon monoxide, polyphenols, formaldehyde, acetaldehyde, acrolein, nitrogen oxides, ammonia, and hydrogen cyanide.[2,3]

Access this article online	
Website: www.njppp.com	Quick Response code
DOI: 10.5455/njppp.2019.9.0727907082019	

These toxic reagents produce free radicals which are reactive oxygen species and nitrogen species such as superoxide, hydroxyl, and peroxide radicals. These free radicals directly as well as by producing inflammatory responses cause oxidative stress to various tissues. This oxidative stress leads to complications such as chronic obstructive pulmonary disease (COPD) in respiratory system, coronary artery disease

(CAD) in cardiovascular system, lung cancer, oral cancer, and atherosclerosis by the involvement of vascular endothelium.[4] It has been seen that more the number of cigarettes smoked per day more will be chanced of complications.[1]

Body responds to oxidative stress produced by smoking by forming some scavenging antioxidant enzymes such as superoxide dismutase (SOD), glutathione peroxidase, and catalase. These enzymes inhibit the oxidation of DNA, proteins, and lipids and control the oxidative stress.[4]

The aim of the present study was to find out the oxidative stress of the smokers by measuring the serum SOD level and compare it with the normal non-smoking subjects and to find if there is any significant alteration in oxidative stress of the smokers.

Aims and Objectives

The aim of the study is to estimate the serum SOD level in non-smoker subjects and smokers of the same age group and compare the oxidative stress of both the groups and to correlate the oxidative stress of the smokers to the pack-years.

MATERIALS AND METHODS

The present study was carried out in the physiology department in assistance with the biochemistry department of a government medical institute. Permission of college ethical committee was taken before starting the study. Written consent was taken from all the subjects included the study.

Thirty non-smoker healthy subjects and 30 smokers of the age group of 40–70 years were selected from the outpatient department of the institute.

The smoker subjects of the age group of 40–70 years with a history of smoking of at least 10 pack-years (A pack-year means 20 cigarettes or 80 beedies smoked each day for 1 year)[5] without any major illnesses such as diabetes, hypertension, or cardiac disorders were selected for the study. Control subjects were non-smoker subjects of the age group of 40–70 years without any major illness were included in the study.

After selecting the subjects, the serum SOD levels were measured. For that, venous blood samples were taken from both the groups. For smokers, the blood sample was taken after 12 h of last smoke to delineate the effect of acute smoking.

Serum SOD levels were measured with the Marklund and Marklund modified by Nandi and Chatterjee.[6,7] Normal level of SOD in serum is 2.93–3.71 units/ml. The mean value of SOD and the standard deviation was calculated for both the groups. The means of both the groups were compared using an "unpaired *t*-test" and statistical significance was calculated. A correlation test was also applied to find out if there any correlation between the pack-year and serum SOD level.

Statistical calculations such as mean, *t*-test, and correlation were done using GraphPad Prism software (version 6.01) and Microsoft Excel software.

RESULTS

From Table 1, it was found that the mean level of serum SOD was less in smokers when compared with non-smokers. Statistically highly significant difference was found using "unpaired *t*-test" ($P < 0.001$). Table 2 shows that there is a statistically significant correlation between the pack-years of smoking and serum SOD level. Negative "*r*" value denotes that this correlation is negative, i.e., if the number of pack-years increases, then the value of the SOD level decreases.

DISCUSSION

In the present study, the serum levels of enzyme SOD in the 30 smokers with a history of more than 10 pack-years of smoking were measured and compared with 30 non-smokers. It was found that the level of SOD was low in smokers (Mean ± SD = 2.50 ± 0.45) as compared to non-smokers (Mean ± SD = 3.01 ± 0.23). This decrease in SOD was statistically significant. On correlating the pack-years to serum SOD level using Pearson's correlation, the "*r*" value was found to be −0.584 and $P = 0.0032$. Thus, a significant negative correlation was found between the pack-years and the serum SOD levels in smokers. This suggests that as the number of the pack-years increases, the serum SOD level decreases. This means that more oxidative stress is produced if the pack-years of smoking increase.

Smoking is known to cause an imbalance between the oxidant and antioxidants in the body. Various toxic harmful substances in the smoke such as nicotine lead to the generation of oxygen and nitrogen-induced free radicals. These radicals are neutralized by free radical scavenging antioxidant system of the body which includes SOD, glutathione peroxidase, and catalase.[4] These antioxidant enzymes, however, get exhausted over a period of time which produces oxidative stress in the body.

Similar study was performed by Gordana *et al*. in smokers with CAD. They measured SOD, glutathione peroxidase, and catalase level in the patients of CAD and found that

Table 1: Comparison of serum SOD level in smokers and non-smokers

Antioxidant enzyme	Smokers	Non-smokers	*P*-value
SOD level (U/ml)	2.50±0.45	3.01±0.23	<0.001*

**P*-value: Statistically highly significant, SOD: Superoxide dismutase

Table 2: Correlation between the duration pack-years of smoking and the serum SOD level in smokers

Pack-years	Serum SOD (U/ml)	Pearson's correlation coefficient (r value)	*P*-value
16.02±3.20	2.50±0.45	−0.5206	0.0032*

**P*-value: Statistically significant, SOD: Superoxide dismutase

the level of SOD is very low in the patients of CAD with a history of smoking in the past.[4] Gavali *et al*. in their study on COPD patients had similar finding that the serum SOD level decreases in patients of COPD with a history of smoking.[8]

van der Vaart *et al*. in their study on acute effects of smoking on oxidative stress concluded that even acute smoking may cause oxidative stress in the smokers.[9] Saha *et al*. in their study also confirmed that long duration of smoking causes more deleterious health hazards as compared to lesser duration of smoking. Further, they concluded that even passive smoking exposure is as dangerous as the primary smoking.[1] Barreiro *et al*., in their study, found that oxidative stress due to smoking may cause skeletal muscle dysfunction, especially diaphragm which may worsen the COPD condition in the smokers.[10] Lipid peroxidation by oxidative stress produces ethane, which can be seen in schizophrenia patients also, so smoking may cause behavioral changes as concluded in a study of Puri *et al*.[11] Smoking may also cause auditory disturbances by inducing hypoxia in the auditory nerve.[12] There are also evidences that smoking causes raised intraocular pressure,[13] lung cancer,[1] etc.

Thus, smoking is a major addiction as well as it is a major public health problem. It is associated with many health problems such as CAD, COPD, cancer, behavioral changes, and ocular and auditory complications. These health problems mostly occur due to oxidative stress produced by the smoking and imbalance of antioxidant enzymes in the body. Secondary smoking also poses same risks as primary smoking. Thus, it is important to conduct more studies with larger sample size and increases the community awareness against smoking.

CONCLUSION

Smoking is a major public health issue. It is associated with oxidative stress by forming the oxygen and nitrogen free radicals which reduces the scavenging antioxidant enzymes like SOD. This puts the smokers at risk of various diseases such as CAD, COPD, and cancer.

A cross-sectional survey of stressors and coping strategies among the first-year medical students in Kerala

Yogesh Balasaheb Gavali[1], Deepmala N. Deore[2,*]

Abstract

Introduction: Compared to the general population medical students have to face more stress, which, if not handled properly, may negatively affect the career of future doctors and community health drastically. To counter this stress, they need appropriate coping strategies. Studies on stress and coping strategies among medical students in India are very few to date and show wide demographic variations in their results.

Materials and Methods: We carried out a cross-sectional survey to find out stressors using a validated Medical Students' Stressor Questionnaire (MSSQ) and we used Brief COPE scale to assess the coping strategies adopted by the first-year medical students in Kerala. Descriptive statistics was used to compile and summarize data.

Result: Most common stress inducer was found to be 'academic related stressor' domain, in which we observed that 88% students had moderate to high level of stress. In this domain, more common stressors were 'examinations' and 'large amount of content to be learnt'. 'Planning' was ranked first with mean score (SD) of 5.72 (1.42), while 'substance use', 2.07 (0.45) was least adopted coping method by them.

Conclusion: Academic stressors were found to be the most common stressor domain in first-year medical students. Timely reduction of such stress using various measures is expected from the educators. Maximum students employed constructive coping strategy i.e. 'planning' but maladaptive 'self-distraction' coping was also seen in substantial number of students who can be helped by guiding them for proper coping methods.

Introduction

The World Health Organization (WHO) has estimated that stress-related disorders will be one of the leading causes of disability by the year 2020.[1] Medical education is one of the highly stressful curricula, wherein the medical students face different types of stressors. The sources of stressors can be academic, economical, personal, social, parental pressure, drive and desire etc. The stress levels were shown to vary in different studies carried out worldwide.[2] Studies on stress among Indian medical students report wide variations in the prevalence of stress (37.3–97%). This wide variation in prevalence may be due to demographic differences in the subjects or different investigating strategies.[3] Supe (1998) identified academic, physical, emotional, and social factors as the principal stressors in a cohort of medical students in Maharashtra, India.[4] Such stress has been suggested to adversely affect the student's health, professional life, and ultimately the health of the society.

Students need effective coping strategies in such a highly competitive educational field. Coping with these stressors needs motivation, guidance, individual and social support. Coping is considered as a stabilizing factor which support an individual to effectively face the stressful situation.[2] Various coping methods used by students to reduce level of stress include effective time management, social support, spiritual activities, and involvement in entertaining activities. Some of the coping strategies are emotion focused that involve taking responsibility, positive reframing, venting and self-blame. Identifying and modifying these strategies at the entry level of medical education will prove crucial for the psychosocial wellbeing of the future doctors.

Studies on stress and coping strategies among medical students in India are very few till date. The present study is an attempt to explore these stressors and coping strategies employed by medical students at the very beginning of their medical education in a medical college in Kerala, India.

Materials and Methods

A descriptive, cross-sectional survey was conducted in a private medical college in Kerala, India. Prior ethical permission was obtained from the Institutional Ethical Committee. The study

was carried out in eighty-nine undergraduate students of both genders, admitted in first year MBBS course. Before enrolment in the study, informed written consent was obtained from all the participants who were willing to take part in the survey. All the subjects were assured of anonymity of the data collected in the questionnaires. Subjects having history of any major illness or any history of recent incidence affecting the mental health were excluded from the study.

The nature of the study was explained to all participants before handing over the questionnaires to them in a physiology lecture class. Besides the questionnaires, basic data such as age and gender were recorded. Two questionnaires were given in printed form to each of the respondents.

The MSSQ (Medical Students' Stressor Questionnaire) which is a validated rating instrument developed in a medical school in Malaysia and also validated in Indian set up by Gupta et al (2015) to measure stress and its sources within the students.[5,6] It consists of 40 items addressing six domains of stressors as mentioned below:

1. Academic-related stressors, which include 'examination system', 'getting poor marks', 'large amount of content to be learnt', 'difficulty understanding the content', 'lack of time to do revision', 'learning context full of competition', and 'having difficulty to answer questions asked by teachers'.
2. Intrapersonal and interpersonal-related stressors include 'conflicts with other students', 'verbal or physical abuse by teachers', 'conflict with personnel'.
3. Teaching and learning-related stressors involve 'appropriateness of tasks given by teachers to students', 'teachers' competency to teach', 'feedback and recognition given by teachers'.
4. Social-related stressors, with items like 'Facing illness or death of patients' and 'discussing the problems of patients'. 'Not getting leisure time with family and friend'.
5. Drive and desire related stressors, like 'Unwillingness to study medicine', 'Parental wish to study medicine by you', 'wrongly choosing the course'.
6. Group activities related stressors including 'Participation in any group discussion and interaction'.

Participants had to respond to each item along a five point Likert scale (0-4) as per the increasing level of severity of stress. All items in the six stressor domains measure the overall stress of the medical student. Mean item scores for each domain was calculated and ranked. Also, the percentage of students facing stress in each domain was measured according to mild (0–1), moderate (1.01–2), high (2.01–3), and severe (3.01–4) degree of stress. Mild stress means no stress or insignificant stress. Moderate stress signifies reasonable stress. Severe and high indicate reasonably significant emotional disturbances with and without interference in daily activities respectively.

Coping strategies were assessed using the "Brief COPE scale", which is a validated and abbreviated version of the COPE Inventory.[7] It consists of 14 scales/categories each having 2 items, thus total 28 items. These items ask what you've been doing to cope with each one. The scales are: 'self-distraction', 'active coping', 'denial', 'substance use', 'use of emotional support', 'use of instrumental support', 'behavioural disengagement', 'venting', 'positive reframing', 'planning', 'humour', 'acceptance, 'religion' and 'self-blame'. The answer choices depend upon how frequently each of these items are applied by the student, that is, 'I haven't been doing this at all', 'I've been doing this a little bit', 'I've been doing this a medium amount', 'I've been doing this a lot' which are scored from 1 to 4, respectively.

Descriptive statistics was used to compile and summarize data. The ranks of stressors and coping strategies based on the mean (SD) score as rated by the medical students were calculated using Microsoft Excel 2016. Also, distribution of subjects according to the severity of stress in each stressor domain was done.

Result

Out of 100 students enrolled in first year MBBS, 94 were present for the scheduled lecture class on the day of this survey. A total of 89 students filled the questionnaires completely, including 28 male and 61 female students. The median age of the participants was 20 years.

None of the participants was found to have severe stress. As shown in table 1, academic related stressor ranked first among the other stressor domains, followed by group activities related stressor and social related stressor with the mean scores of 2.11, 1.57 and 1.38 respectively. Drive & desire related stressor domain had the least mean score of 0.69.

In academic related stressor domain, we observed that 88% students had moderate to high stress and 66% students had high degree of stress. Group Activities Related Stressor domain included 27% participants in high degree stress category as shown in table 2.

Table 1: Stressor domains ranked by their mean scores

Stressor domain	Mean (SD)
Academic Related Stressor	2.11 (0.72)
Group Activities Related Stressor	1.57 (0.82)
Social Related Stressor	1.38 (0.70)
Interpersonal & Intrapersonal Related Stressor	1.35 (0.82)
Teaching and Learning Related Stressor	1.31 (0.74)
Drive & Desire Related Stressor	0.69 (0.71)

Table 2: Distribution of subjects according to the severity of stress in each stressor domain (N=89)

Stressor domain	Mild stress N (%)	Moderate stress N (%)	High stress N (%)
Academic Related Stressor	8 (8.99)	22 (24.72)	59 (66.29)
Interpersonal & Intrapersonal Related Stressor	36 (40.45)	34 (38.20)	19 (21.35)
Teaching and Learning Related Stressor	37 (41.57)	39 (43.82)	13 (14.61)
Social Related Stressor	32 (35.96)	41 (46.07)	16 (17.98)
Drive & Desire Related Stressor	68 (76.40)	17 (19.10)	4 (4.49)
Group Activities Related Stressor	27 (30.34)	38 (42.70)	24 (26.97)

Planning was the most utilized coping method by the participating students, while substance use was least adopted by them in case of stressful situation (Table 3).

Table 3: Coping strategies ranked by their mean scores

Coping strategies	Mean (SD)
Planning	5.72 (1.42)
Self-distraction	5.60 (1.78)
Religion	5.51 (2.05)
Positive reframing	5.44 (1.74)
Acceptance	5.39 (1.60)
Active coping	5.38 (1.51)
Self-blame	5.21 (1.89)
Use of instrumental support	4.93 (1.83)
Use of emotional support	4.72 (1.69)
Venting	4.63 (1.55)
Humor	4.18 (2.04)
Behavioral disengagement	3.66 (1.51)
Denial	3.46 (1.60)
Substance use	2.07 (0.45)

Discussion

Medical education and career in India are very stressful and many researchers have concluded that, compared to general population medical students are more subjected to stress. Such stress has been making them prone to suicide, depression and drug abuse. Efficient coping strategies can buffer the impact of stressful situations on the mental and physical wellbeing of medical students and finally improve patients' lives and community health.[8]

Plenty of literature is available proving the presence of stress among medical students in different countries, but few studies have been done to reveal different stressors and the coping strategies, particularly in India. Considering this, an assessment was done in the present study using MSSQ to find out stressors and Brief COPE inventory was used to find out coping strategies among medical students in a medical college in Kerala.

The present survey revealed that maximum students were getting stressed due to the academic stressors, out of those, 66% had high stress. Out of the different factors included in academic domain of stressors, it was observed from their responses that, students were getting stressed more due to 'examinations', 'large amount of

content to be learnt', 'heavy workload', and 'learning context- full of competition'.

'Group activities related stressor was the next common stress inducing domain, wherein, 27% students had high stress. In this domain, students were having more stress in 'participation in class presentation' and 'feeling of incompetence'. Drive and desire related high stress was observed merely in 3% of the participants.

Similar result revealing academic stressors as the source of maximum stress was obtained by Gupta et al (2015) in India.[6] Saxena et al (2014) carried out a study in Dehradun, India and found that moderate to high academic stress was present among 79% of students.[9] Research by Yusoff et al (2011) in Malaysia and Sarkar et al (2015) in Chhattisgarh also found that academic related issues were the most common forms of stressors among the medical students.[8,10]

Contrary to the present study, Samira et al (2015) in Riyadh concluded that, high stress causing stressors were worrying about future, trouble with friends, room-mate conflict, hearing bad news, and low self-esteem.[2]

Regarding the coping strategies adopted by the students, we found maximum students adopted adaptive (constructive) coping strategies like 'planning' with mean score (SD) of 5.72 (1.42) more than maladaptive or avoidant strategies such as 'self-distraction', 5.60 (1.78). 'Substance use' was the least adopted coping method.

In a similar study by Shakthivel et al (2017) in Tamil Nadu, India, it was revealed that the most commonly employed coping mechanism was 'religion' followed by 'self-distraction'.[11] Results obtained by Samira et al (2015) showed 'self-blame' and 'self-criticism' as the common reactions to stress. Religious coping was frequently adopted as a coping measure, while use of alcohol or other drugs was found to be rare.[2] Sreeramareddy et al (2007) found positive reframing, planning as the coping strategies commonly used by students in their institution in Nepal.[12]

Such differences in the finding major stressors and coping mechanisms in different studies may be attributed to geographical, cultural, and social environment of the students and different rating scales used. Thus, it is crucial for the medical educators to assess the stressors and coping strategies of their students at the beginning of medical education and mentor them to use desirable coping strategies to reduce stress, which will ultimately help the society to have better doctors and better health.

Further research encompassing students from different semesters, correlation of stressors and coping strategies with cultural and demographical parameters is suggested to get in to the deeper insights of these stressors.

Conclusion

The first-year medical students in the present study setup showed to suffer maximally from the academic related stressors, particularly stress due to examinations and large amount of content to be learnt. This stress can be alleviated by mentoring and motivating them to improve their studying styles, plan the study time, maintain a healthy lifestyle, give plenty of time to revise and apply anxiety reduction techniques.

Maximum students employed constructive coping strategy i.e. 'planning' but maladaptive 'self-distraction' coping was also seen in substantial number of students. Such students can be helped by mentoring, establishing wellness clinics and organizing personality development programmes within the campus itself.

Acknowledgments

We thank to all participating students, our colleagues and the staff of our college for contributing to this survey. Also, special thanks to Dr Muhamad S B Yusoff for making the MSSQ available for the study.

Abstract

Introduction: Many of the students admitted in Indian medical colleges have had school education in vernacular medium. There exists a general opinion that such students find it difficult to cope up with medical academics in English medium as they think in one language and study in another. This study was carried out to find whether such language barrier affects their professional performance.

Materials and Methods: This multi-centric retrospective observational study was carried out in 274 medical students from four government medical colleges in Marathwada region of Maharashtra, India. The medium of instruction during their school education was recorded from their 10th standard mark-sheets. The marks of final year MBBS were obtained from their academic record in academic section of the colleges. The data were analysed using one-way ANOVA.

Result: There was statistically no significant difference of professional performance among the medical students with different media of instruction in their school education (P=0.1149).

Conclusion: Medium of instruction of school education doesn't have any significant effect on professional performance of medical students.

Keywords: Medium of instruction, Mother tongue, Language barrier, Professional performance.

Introduction

There are nearly 5,000 languages in use in the world today. Every advanced country has its own national language. India has more languages compared to any other country in the world. Hindi is the primary language spoken by 30% of Indian population. Marathi and Urdu are the major languages of communication and instruction in Marathwada region of Maharashtra. English though not a primary language but is ubiquitous to India, a former British colony. English is certainly very important in higher education and played a crucial role in developing India as an economic power.[1] English language as a medium of instruction plays the key role in medical students' learning in India. Therefore, it is the popular belief in the society that the students' academic achievement depends largely on their English language abilities.

But productive learning process does not rely only on the knowledge about English language, it also involves other factors like communication skills, supportive teachers, supportive home environment and motivation. Learners get actively involved in the learning process through discussion, reading, writing, and analysis, rather than passively getting instructions. To learn, students have to communicate and exchange the information among them, which needs fair understanding of language. Being a tool to communicate, language allows students to convey ideas, facts, concepts and feelings to each other, which may be better done through their mother tongue or vernacular medium of instruction.

Studies show that medical undergraduates undergo multiple stressors. Mandal et. al. (2012) found that, understanding the medium of instruction, was significantly related to performance in medical students.[2] There is much literature available on the effect of medium of school education and performance of the students in various professional courses unlike in medical profession in India. So, the present study is an attempt to assess whether mode of instruction during school education really affects professional performance and whether students from English-medium schools perform better in MBBS academics than those from vernacular medium schools.

Materials and Methods

The present study is a multicentric retrospective observational study. The number of participants involved was 274 out of 350 students of both genders, passed in MBBS from four government medical colleges in Marathwada

region of Maharashtra. The colleges included were Government Medical College, Aurangabad, SRTR Medical College, Ambajogai, Government Medical College, Latur and Dr. Shankarrao Chavan Government Medical College, Nanded.

Ethical approval was obtained from the Institutional Ethical Committee of Government Medical College, Aurangabad. Before enrolment in the study, informed written consent was obtained from all the students who were willing to take part in the survey. Permission of the Deans of all the institutions was sought. Students with diagnosed psychological disorder were excluded from the study. Basic data like age and sex was collected. The medium of instruction during their school education was recorded from their 10th standard mark-sheets. Quantitative assessment of professional performance was done using their final MBBS marks, obtained in both practical and theory. The marks of final year MBBS were recorded from the mark-sheets available with the students or their academic record available in the academic section of the colleges involved in this study. Comparison of marks obtained in final MBBS was done among students from different media of instruction during their school education using one-way ANOVA in statistical software GrapPad Prism (Version 6.01).

Result

The study included 274 (78.29%) students out of 350 students passed in the final year MBBS. Remaining students were unwilling to participate in the study. Out of total 274 participants, 158 were males and 116 were females. The median age of the participants was 19.42 years. Frequency distribution of students as per the medium of instruction of their school education before getting admitted to MBBS course is shown in table-1. Maximum number of participants (67.15%) have got their school education in native Marathi language followed by English (25.55%).

Table1: Distribution of subjects according to the medium of instruction during school education

Medium of Instruction	Frequency (%)
Marathi	184 (67.15%)
English	70 (25.55%)
Urdu	12 (4.38%)
Hindi	8 (2.91%)

In the current study, we found that students who learned in Hindi during their school education had achieved maximum mean percentage score (60.90%) while Urdu medium students got the least marks (57.66%) as indicated in Fig.1.

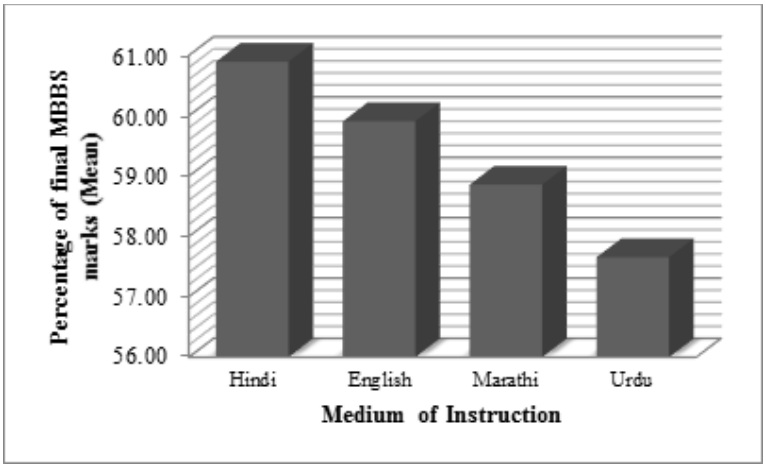

Fig. 1: Academic performance of medical students with different media of instruction during their school education

As shown in the table 2, when we compared the final MBBS marks of all the students belonging to different media of instruction during their school education, we did not find any statistically significant difference between their scores (P=0.1149).

Table 2: Comparison of academic performance of medical students with different media of instruction during their school education

Medium of instruction	Hindi	English	Marathi	Urdu	P-value (One-way ANOVA)
Percentage of final MBBS marks [Mean (SD)]	60.90 (5.31)	59.91 (3.7)	58.86 (4.35)	57.66 (4.77)	0.1149 (NS)

P = NS: Statistically not significant.

Discussion

English is considered a foreign language for Indian students. All the professional institutions have English as a medium of education. There is a common belief in the society that students weak in English language may not understand and reproduce the knowledge in examinations and also, the failure and poor performance in examinations by the medical students may be because of this factor. So, in recent years there has been a dramatic surge in English medium schools in India with many parents insisting to admit their children in those schools rather than in vernacular schools. This hypothesis was assumed in our study. We included the freshly passed final year MBBS students and compiled their academic performance in university examinations. The present study shows statistically no significant difference between mean marks obtained by the students of different media of instruction in their school education. But, when compared individually, all the students that scored highest marks in the exam belonged to Marathi medium which is the most prevalent language in this region. This indicates that students from vernacular medium had no deficits in English language to the extent that can adversely affect their comprehension and performance. This disproves the general assumption that, to be proficient in medical academics, one needs command over English language.

Mother tongue is defined by UNESCO as "the language which a person acquires in early years and which normally becomes their natural instrument of thought and communication." According to UNESCO, mother tongue education is "Education which uses its medium of instruction a person's mother tongue, that is, the language a person has acquired in early years and which normally has become his or her natural instrument of thought and communication." The importance of mother tongue in the cognitive, linguistic, personal and educational development of students cannot be ignored.[3]

There is no doubt that the basic knowledge of English language is must for achieving excellence in medical education worldwide. Despite international communication among clinicians and scientists occurring almost exclusively in English, communication with patient and colleagues within individual countries, teaching, and some scientific activities are still conducted in the local mother tongues.[4] The vast knowledge of medical sciences cannot be memorized but can be retained by understanding and active learning. A learner can do this efficiently by communicating in his own language.

In countries like India, the foundations of reasoning and memory in basic subjects are mostly founded in the vernacular languages i.e. primary language (L1), with minimal exposure to English as a secondary language (L2). Even then, we found statistically no difference in their performance on comparing with that of English medium students. This indicates that basic education in mother tongue may reinforce the learning in secondary language. Even though medium of instruction is English in Russia, China, Japan, Mexico and other countries, their medical education system also give enough importance to native languages other than English and they have produced excellent human resources trained in medicine as well as biomedical research. Many Indian students learn their languages to undergo medical training in these countries.[5]

Studies on advantages of teaching medicine in English, assisted by using student's mother tongue, had been done before in other countries.[6-8] This inclusion of the mother language in teaching medicine is seen as a way to free learners from the linguistic bias of thinking in one language and studying in another i.e. students with background of vernacular medium school read medicine in English and interpret in vernacular languages.[9]

Many studies in literature show the important role of mother tongue for second language acquisition. Primary language (L1) helps learners to arrange and rearrange the secondary language (L2) data for better understanding and interpretation. Thus, L2 acquisition is a developmental process, assisted by L1.

When learning a new language, we build brain networks to process and represent the acquired words and syntax and integrate these with existing language representations i.e. the brain is able to reuse characteristics of the mother

tongue when the new language being taught is grammatically similar. Results of a study by Weber et al (2016) indicated an overlap in neural mechanisms for native and new language constructions with sufficient structural similarities.[10] Studies have shown positive effects of mother tongue on comprehension itself. Price et al (1999) observed that comprehension of words in mother tongue activated more of the temporal lobe including temporal pole than did words in second language.[11]

Similar results were obtained in a study conducted by An E He (2012) in China, who pointed out the potential advantages of systematic use of mother tongue as learning or teaching resource in target language instruction. They observed that use of L1 as learning and teaching resources provided a support for learners. By making explicit reference to learners' conceptual understanding of mother tongue, and by raising their conscious awareness of similarities and differences between Chinese and English, learners' existing comprehension could be enhanced. Also, using L1 as learning and teaching resources increases learning efficiency and smoothened the learning process. Taking advantage of what students have already known conceptually, strategically, and linguistically allowed a "all round development" and "intellectual continuity" in language development.[12] Similarly, Sabbour et al (2012) suggested that teaching in Arabic language was appropriate in some specialties of medicine in Arab countires.[9] Khattak et al (2005), in a similar study in Pakistan, concluded that there is no effect of language as a medium of education during primary and secondary school upon the results of university professional MBBS examinations.[13]

As we consider this as a pilot study, further research involving more number of students from different regions in India is suggested to get more details on this issue. Also, similar studies should be carried out on medical students to correlate media of instruction with their professional performance qualitatively by interviewing them and assessing through questionnaires.

Conclusion

The present study shows no significant effect of medium of instruction during school education on the performance of students in medical colleges. So, it gives a message to the community that it is needless to emphasize on English medium of instruction for school education and students from vernacular medium schools can very well cope with English language during medical academics. Learning medicine in English, being the universal medium of instruction, may prove more efficient if it is supported by teaching and learning major concepts in students' mother tongue.

Abstract

Background: Attitudes and belief toward mental illnesses are important factors that affect perception of mental health. Knowing the attitude of medical students towards psychiatry and mental illnesses is of utmost importance as they are future care provider. Current study is conducted to assess the attitude of medical students towards mentally ill patients and mental illnesses, to identify correlation of attitude score with personal and family history of mental illness and, to compare the score among students of the three year-wise groups.

Method: The study population included 219 students of first, second and third professional MBBS. We designed an online data collection tool and executed it using the Google Forms. The Google Form link to the questionnaire was sent to the enrolled participants via the identified WhatsApp groups or individual number. Beliefs toward Mental Illness (BMI) scale was used to assess attitude towards mental illnesses which is a 21-item self-report measure of negative stereotypical views of mental illness. The results of the study were examined and analyzed by using Statistical Package for Social Sciences (SPSS 25.0).

Results: Out of total 21 items of the BMI scale, students showed positive attitude on majority of items. The mean score for BMI scale and per item mean score for the scale were towards positive attitude. Majority of students agree that a mentally ill person is more likely to harm others than a normal person and that mental disorders would require a much longer period of time to be cured than would other general diseases. Higher per item mean score for dangerousness and, incurability subscale showed their negative attitude. An increasing trend of positive attitude has been seen with an increase of education level and exposure towards the subject.

Conclusions: Medical students show variable scores on belief towards mental illness scale, its subscales and, individual items. Admitting this prevailing stigma needs to be acknowledged and openly discussed with medical students in order to overcome these views. Providing adequate education on mental illnesses and attached negative attitudes or myths can change these negative beliefs.

Keywords: Medical students, psychiatry, mental illnesses, stigma, dangerousness.

1. Introduction:

Attitudes and belief toward mental illnesses are important factors that affect perception of mental health. The prejudiced and negative attitudes or stigma towards people with mental illness are widespread. In our society, health professionals have similar views about those with mental health problems and mentally ill patients. Literature suggests that people diagnosed with mental illness are considered by the majority of the society as people who are dangerous, loathed, stranger and somebody whose actions cannot be predicted.[1] Globally, psychiatry as a subject, psychiatrists as professionals, and patients with psychiatric disorders are subjected to cultural stereotypes and negative attitude by the general population. What is of alarming concern is that these prejudices exist within the medical community as well.[2-6] Stigma toward mental illness is an influential factor leading to negative views among medical students toward psychiatry. Lack of knowledge and awareness about mental illnesses among the students is associated with the negative attitudes towards mental illness in the community. For medical students during their training, educational intervention targeted towards these negative attitudes may be more effective than doctors who have already completed their training because research has shown as they carry on through their career, their attitude harden and become more resistant to change.[7] The concept of iatrogenic stigma is used to describe the stigma caused or perpetuated by mental health professionals.[8] This stigma and negative attitudes can affect the quality of life for people with mental illness. There may be various reasons for this negative attitude such as lack of accurate information about mental illness and lack of contact with individuals with mental illness.[9]

While some studies have suggested that aspiring young doctors have a favorable opinion about psychiatry as a branch[10], other studies have suggested that medical students' attitude toward psychiatry is unfavorable.[11-17]

A doctor's attitude towards persons with psychiatric illness and psychiatry should involve an impression of an empathetic listener and should have non-judgmental approach. Knowing the attitude of medical students towards psychiatry and mental illnesses is of utmost importance as they are future care provider. To improve psychiatric training in this population beliefs and attitude toward psychiatric illnesses and need to be assessed and understood.

The reasons for studying the attitude specifically among medical students are that firstly as a doctor they can play an important role in decreasing negative attitude and, secondly the results from the study will help to focus strategies to change attitudes of this group. The comparison among various groups in present study will help in understanding the impact of successive undergraduate training years. The findings may help in understanding the various points of strength and lacunae in the current undergraduate curriculum regarding mental health.

Objectives:

The objectives of the current online study were-

1. To assess the attitude of medical students towards mentally ill patients and mental illnesses
2. Correlation of attitude score with personal and family history of mental illness, and
3. Comparison among students of the three year-wise groups.

2. Methodology

Study population and study area: The study population includes all the students who have

enrolled in MBBS course (first year, second year and final year) at Ananta Institute of Medical Science and Research Centre, Rajsamand, Rajasthan. Those students who will give their consent to participate in the study will be included and rests will be excluded at their will.

Study Duration: one year, June 2020 to May 2021.

Sampling techniques and sample size

Samples were obtained using stratified random sampling method. The 3 batches of medical students viz first year professional, second year professional and third year professional which were considered as strata collectively develop a sampling frame of 450 students. The minimum sample size on assumption of 95% level of significance, 5% error and 85% expected proportion was 196. After 12% adjustment of non- responders' students the final sample size was 219.

Undergraduates in the 1st year had not received formal exposure to psychiatry yet, students of 2nd year also have not attended clinical posting or lecture in psychiatry while students of Final year students had completed clinical posting and theory lectures in psychiatry. The institute is having well-functioning psychiatry department with adequate teaching staff and a good in-flow of patients in the psychiatry OPD as well as inpatient department.

Study procedure and statistical Analysis: After unlock 1.0 was announced by the Government of India from 8th of June 2020, the cases of COVID-19 were increasing all over India including Rajasthan. Hence there was risk of disease transmission by taking interview in person therefore we decided to use WhatsApp Messenger for enrolling potential participants and Google forms for filling up their response. The study was approved by institute ethics committee.

Tools: We designed an online data collection tool and executed it using the Google Forms (via docs.google.com/forms). The Google Form link to the questionnaire was sent to the enrolled participants via the identified WhatsApp groups or individual number.

Socio-demographic variables included age, gender, marital status, background, past personal history of mental illness, known history of mental illness in the family were described using descriptive statistics.

Beliefs toward Mental Illness (BMI) scale was used to assess attitude towards mental illnesses. The BMI scale is a 21-item self-report measure of negative stereotypical views of mental illness. (18) There is a total Score and the score of three sub-scales based on factor analysis: dangerousness, poor social and interpersonal skills, and incurability. There are five items in subscale dangerousness, ten items in poor interpersonal and social skills scale and six items in incurability subscale. Items are rated on a six-point Likert scale ranging from 'completely disagree' (0) to 'completely agree' (5), with higher scores reflecting more negative beliefs. In the primary validity study, Cronbach's alpha was high among American (0.89) and Asian students (0.91). The measure holds promising evidence of validity.

The results of the study were examined and analyzed by using Statistical Package for Social Sciences (SPSS 25.0). The categorical variables were described by numbers and percentages while continuous variables were described by average and standard deviation. Normality of attitude was checked using Kolmogrov-Smirnov test. After testing normality condition, the association and relationship between the variables were tested Pearson correlation by Student's t test and one way analysis of variance (ANOVA). The level of significance was considered at $P<0.05$.

3. Results

A total 219 number of students were participated in the online study. The sample comprised of 41.55% of male students and 58.44% of female students. Majority of the students were unmarried (97.26%), belonging to urban background (79.45%), having negative past personal history of psychiatric illness (86.75%) and negative family history for psychiatric illnesses (75.79%).

Table 1: Socio-demographic characteristics of respondents

Variables	Participants N (%)
Sex	
Male	**91 (41.55%)**
Female	**128 (58.44%)**
Marital Status	
Married	**6 (2.73%)**
Unmarried	**213 (97.26%)**
Place of residence	
Urban	**174 (79.45%)**
Rural	**45 (20.54%)**
MBBS Batch	
First year professional	**49 (22.37%)**
Second year professional	**138 (63.01%)**
Third year professional	**32 (14.61%)**
Had mental illness in past:	
Yes	**29 (13.24%)**
No	**190 (86.75%)**
Is someone in your family/ friends/ relative is having mental illness:	**53 (24.21%)**
Yes	**166 (75.79%)**
No	
If yes, then	
Friends	**7(13.2%)**
Family	**26(49.05 %)**
Relative	**20(37.73%)**

Table 1 shows socio-demographic characteristics of respondents.

Attitudes of students towards mental illness

a) Attitude by Items of the subscales

Table 2: Dangerousness subscale of BMI scale (item wise responses, percentage of participants regarding statements on the beliefs about mental illness)

Statement	**Response***					
	0	**1**	**2**	**3**	**4**	**5**
A mentally ill person is more likely to harm others than a normal person	28 (12.8%)	15 (6.8%)	36 (16.4%)	85 (38.8%)	26 (11.9%)	29 (13.2%)
	79 (36%)			140 (64%)		
Mental disorders would require a much longer period of time to be cured than would other general diseases	10 (4.6%)	8 (3.7%)	19 (8.7%)	55 (25.1%)	51 (23.3%)	76 (34.7%)
	37 (17%)			182 (83%)		
It may be a good idea to stay away from people who have psychological disorder because their behaviour is dangerous	73 (33.3%)	47 (21.5%)	41 (18.7%)	41 (18.7%)	7 (3.2%)	10 (4.6%)
	161 (74%)			58 (26%)		
Mentally ill people are more likely to be criminals	69 (31.5%)	47 (21.5%)	35 (16.0%)	45 (20.5%)	13 (5.9%)	10 (4.6%)
	151 (69%)			68 (31%)		
I am afraid of people who are suffering from psychological disorder because they may harm me	80 (36.5%)	47 (21.5%)	31 (14.2%)	50 (22.8%)	4 (1.8%)	7 (3.2%)
	158 (72%)			61 (28%)		

* Denotes 0 = Completely disagree, 1 = Largely disagree, 2 = somewhat disagree, 3 = somewhat agree, 4 = Largely agree, 5 = Completely agree

Table 2 shows item wise responses and percentage of participants regarding statements on the beliefs about mental illness on dangerousness subscale of the BMI scale

Table 3: Poor social and interpersonal skills subscale of BMI scale (item wise responses, percentage of participants regarding statements on the beliefs about mental illness)

Statement	**Response**					
	0	**1**	**2**	**3**	**4**	**5**
The term 'psychological disorder' makes me feel embarrassed	123 (56.2%)	30 (13.7%)	16 (7.3%)	24 (11.0%)	12 (5.5%)	14 (6.4%)
	169 (77%)			50 (23%)		
A person with psychological disorder should have a job with only minor responsibilities	43 (19.6%)	30 (13.7%)	49 (22.4%)	58 (26.5%)	27 (12.3%)	12 (5.5%)
	122 (56%)			97 (44%)		

I am afraid of what my boss, friends and others would think if I were diagnosed as having a psychological disorder	70 (32.0%)	24 (11.0%)	24 (11.0%)	57 (26.0%)	17 (7.8%)	27 (12.3%)
	118 (54%)			101 (46%)		
It might be difficult for mentally ill people to follow social rules such as being punctual or keeping promises	37 (16.9%)	29 (13.2%)	55 (25.1%)	38 (17.4%)	37 (16.9%)	23 (10.5%)
	121 (55%)			98 (45%)		
I would be embarrassed if people knew that I dated a person who once received psychological treatment	131 (59.8%)	29 (13.2%)	17 (7.8%)	26 (11.9%)	12 (5.5%)	4 (1.8%)
	177 (72%)			61 (28%)		
A person with psychological disorder is less likely to function well as a parent	43 (19.6%)	45 (20.5%)	35 (16.0%)	57 (26.0%)	22 (10.0%)	17 (7.8%)
	123 (56%)			96 (44%)		
I would be embarrassed if a person in my family became mentally ill	150 (68.5%)	26 (11.9%)	15 (6.8%)	13 (5.9%)	7 (3.2%)	8 (3.7%)
	191 (87%)			28 (13%)		
Mentally ill people are unlikely to be able to live by themselves because they are unable to assume responsibilities	45 (20.5%)	51 (23.3%)	50 (22.8%)	43 (19.6%)	12 (5.5%)	18 (8.2%)
	146 (67%)			73 (33%)		
Most people would not knowingly be friends with a mentally ill person	33 (15.1%)	22 (10.0%)	36 (16.4%)	62 (28.3%)	27 (12.3%)	39 (17.8%)
	91 (42%)			128 (58%)		
I would not trust the work of a mentally ill person assigned to my work team	61 (27.9%)	40 (18.3%)	44 (20.1%)	53 (24.2%)	10 (4.6%)	11 (5.0%)
	145 (66%)			74 (34%)		

0 = Completely disagree, 1 = Largely disagree, 2 = somewhat disagree, 3 = somewhat agree, 4 = Largely agree, 5 = Completely agree

Table 3 shows item wise responses and percentage of participants regarding statements on the beliefs about mental illness on poor social and interpersonal skills subscale of the BMI scale

Table 4: Incurability subscale of BMI scale (item wise responses, percentage of participants regarding statements on the beliefs about mental illness)

Statement	**Response**					
	0	**1**	**2**	**3**	**4**	**5**
Psychological disorder is recurrent	17 (7.8%)	17 (7.8%)	45 (20.5%)	77 (35.2%)	34 (15.5%)	29 (13.2%)
	79 (36%)			140 (64%)		
Individuals diagnosed as mentally ill suffer from its symptoms throughout their life	53 (24.2%)	46 (21.0%)	41 (18.7%)	53 (24.2%)	10 (4.6%)	16 (7.3%)
	140 (64%)			79 (36%)		
People who have once received psychological treatment, are likely to need further treatment in the future	19 (8.7%)	38 (17.4%)	29 (13.2%)	82 (37.4%)	29 (13.2%)	22 (10.0%)
	86 (39)			133 (61%)		
I believe that psychological disorder can never be completely cured	139 (63.5%)	19 (8.7%)	21 (9.6%)	17 (7.8%)	9 (4.1%)	14 (6.4%)
	179 (82%)			40 (18%)

	76 (35%)			143 (65%)		
Psychological disorder is unlikely to be cured regardless of treatment	53 (24.2%)	31 (14.2%)	46 (21.0%)	46 (21.0%)	17 (7.8%)	26 (11.9%)
	130 (59%)			89 (41%)		

0 = Completely disagree, 1 = Largely disagree, 2 = somewhat disagree, 3 = somewhat agree, 4 = Largely agree, 5 = Completely agree

Table 4 shows item wise responses and percentage of participants regarding statements on the beliefs about mental illness on incurability subscale of the BMI scale

b) Attitudes by Subscale

There are five items in subscale dangerousness, ten items in poor interpersonal and social skills scale and six items in incurability subscale.

Table 5: Per item Mean and 95% CI for the three subscale and overall score of BMI scale

Subscale	**M(SD)**	**95 %CI**
Dangerousness	2.17(0.90)	2.77, 1.56
Poor interpersonal and social skills	1.77(0.92)	2.99, 0.54
Incurability	2.21(0.92)	2.94, 1.47
Full BMI scale	1.99(0.80)	4.22, -0.24

* M- Mean, SD- Standard deviation, CI- Confidence interval

Table 5 shows per item mean and 95% confidence interval for the three subscales and overall score of BMI scale.

c) Associates of attitudes

The differences in the attitude scores in different independent variables have two categories were determined by independent sample t tests. And, difference in attitude score in independent variables having more than two categories was determined by the one-way ANOVA.

As per Kolmogrov-Smirnov test statistic (D)results in 0.04762 which means that data is normally distributed. So independent sample t test has been applied to find out difference in attitude score by socio demographic characteristics.

Table 6: Difference in attitude score by socio-demographic characteristics

Characteristics	M(SD)	Diff.*(95% CI)	p-value
Sex			
Male	42.67(17.20)	1.24(-3.31,5.79)	0.59
Female	41.43(16.61)		
Marital status			
Married	60.17(9.06)	18.73(5.20,32.27)	**0.007**
Unmarried	41.43(16.72)		
Place of residence			
Urban	42.80(16.32)	4.18(-1.35, 9.71)	0.13
Rural	38.62(18.48)		
Had mental illness in past			
Yes	40.10(15.14)	2.12(-4.50, 8.74)	0.52
No	42.23(17.09)		
Is someone in your family/ friends/ relative is having mental illness:			
Yes	39.64(17.34)	3.03(-2.19, 8.27)	0.25
No	42.68(16.65)		

*Diff. =Difference in mean, (lower bound, upper bound)

Table 6 shows difference in attitude score by socio-demographic characteristics. Married students (N=6) had higher BMI score than unmarried students (N=213) and the difference was statistically significant. On further analysis it was found that of these six married students, five had positive response for history of mental illness in family, friend or any relative, also two had positive history of past mental illness. The difference among groups was not statistically significant for other characteristics.

Table 7: Difference in attitude towards mental illness by education level of students

Characteristics	M(SD)	F- value	p-value	p-value trend
Batch		9.11	**<0.0001**	**<0.0001**
I MBBS	48.11(14.34)			
II MBBS	43.63(14.71)			
III MBBS	41.08(15.21)			

*M= mean, SD= standard deviation, F=degree of freedom, p= p value

Table 6 shows that There is increase trend in positive attitude in medical students with increase in their education level ($p<0.0001$).

There was significantly positive attitude towards mental illness among III MBBS students than II MBBS and, among II MBBS than I MBBS ($p<0.0001$). An increasing trend of positive attitude has been seen with an increase of education level and exposure towards the subject.

4. Discussion

The current online study was planned to assess the attitude of medical students towards mentally ill patients and mental illnesses, to find correlations of attitude score with sociodemographic and clinical variables and, to compare the score among students of the three year-wise groups.

Out of total 21 items of the BMI scale, students showed positive attitude on majority of items (fifteen items) and negative attitude on few items (six items). The mean score for BMI scale was 41.99 and per item mean score for the scale was 1.99. This score is towards positive attitude. Jilowa et al also found in their study that Nearly 84% of second-year medical students and 52% of interns had positive attitude toward psychiatry. (19) In their study, Risal et al also found overall positive or neutral attitudes towards mental illness and psychiatry among the medical students and interns in their institute. (20)

In our study we found that majority of students agree that a mentally ill person is more likely to harm others than a normal person (64%) and that mental disorders would require a much longer period of time to be cured than would other general diseases (83%). Kodakandla et al conducted a study on Attitude of interns towards mental illness and psychiatry and found that majority of the interns believed that mentally ill person is more likely to harm others and that mental illness require a much longer time to be cured than other general diseases. (21) In our study majority (58 percent) of students agree that most people would not knowingly be friends with a mentally ill person. Jyothi NU et al also found majority (96 percent) of participants agreed with the statement. (22)

In our study we found that majority of students agree that psychological disorder is recurrent (64%), that people who have once received psychological treatment are likely to need further treatment in the future (61%), and that the behaviour of people who have psychological disorders is unpredictable (65%). Kodakandla et al also found that majority of participants (76%) believed that psychological disorder is recurrent and that the behavior of patients with psychological disorder is unpredictable (79%); two third of them (68%) were of the opinion that people who have once received psychological treatment are likely to need further treatment in the future. (21) Jyothi NU et al also found similar findings in a study on college students. (22)

Students showed per item mean score 1.77 for poor interpersonal and social skill subscale which is towards positive attitude. Higher per item mean score 2.17 for dangerousness subscale and 2.21 for incurability showed their negative attitude. In a community Study on Attitudes to and Knowledge of Mental Illness in Tehran, Ghanean H et al found that around half participants agreed that people with a mental illness “are dangerous”. (23) Contrary to our findings *Kodakandla et al* found that only one third (31%) interns believed that psychological illness is unlikely to be cured regardless of the treatment. (21)

Married students showed statistically significant higher BMI score compared to unmarried students. On further analysis it was found that of these six married students, five had positive response for history of mental illness in family, friend or any relative and, two had positive history of past mental illness. So,

these two factors might have caused higher stigma in this small sample. The attitude score was not associated statistically significantly with other sociodemographic and clinical variables.

There was significantly positive attitude towards mental illness among III MBBS students than II MBBS and, among II MBBS than I MBBS ($p<0.0001$). An increasing trend of positive attitude has been seen with an increase of education level and exposure towards the subject. Similar to our study Aruna et al also highlighted exposure to psychiatry could improve the knowledge base of medical students. (24) Tharyan et al also found that psychiatric education positively influences the attitudes of medical students towards mental illness and some aspects of psychiatry. (25) However, providing clinical training in psychiatry during under graduation seems to improve the attitude toward people with mental illness. (16, 25-27) The favorable impact of psychiatry posting on the attitude of medical students towards mentally ill has been found in previous studies from western countries. (28) Work by Mas and Hatim (2002) from Malaysia found that final year MBBS students had more favorable attitude towards mentally ill as compared to the first-year students. (29)

The National medical commission (formerly Medical Council of India) has implemented Attitude, Ethics and Communication module (AETCOM) in all medical colleges in India in August 2019. (30) The cognitive components, behavioural attitudes and ethical dimensions of AETCOM module will change the approach of future doctors to psychiatry and person with psychiatric illness. Focusing more on clinical exposure and skills the new competency based medical education (CBME) programme has increased the duration of undergraduate clinical posting to total four weeks and total 40 hours for teaching from two weeks and 25 hours pre CBME respectively. This sequential introduction of clinical posting during second professional MBBS followed by theory class and clinical posting during third MBBS part-I will be more helpful in understanding of the subject. In future, mandating psychiatry as an independent subject of examination in under graduation assessment may prove a milestone step in medical education. So, it may be expected that this increased exposure will help in removing the existing negative attitudes towards psychiatry and person with psychiatric illness.

Suggestions:

Admitting the prevailing stigma needs to be acknowledged and openly discussed with medical students in order to overcome these views. Prevailing stigma and the negative attitudes about mental illnesses affect both patient caring and psychiatry as a career choice. The development of educational strategies enabling initial interest shown during the early clinical exposure needs to be maintained. Providing public education on mental illnesses and attached negative attitudes or myths can change these negative beliefs in general public. To promote psychiatry as a career, interested students need to have increased access to an in-depth experience of psychiatry, including “enrichment activities” such as electives in psychiatry.

Conclusions:

Medical students show variable scores on belief towards mental illness scale, its subscales and, individual items. Admitting this prevailing stigma needs to be acknowledged and openly discussed with medical students in order to overcome these views. Providing adequate education on mental illnesses and attached negative attitudes or myths can change these negative beliefs.

Implications of the Study:

This study will help in understanding of belief of medical students towards mental illnesses. The comparison among various groups in

present study will help in understanding the impact of successive undergraduate training years.

Limitations:

This was a cross sectional study with small sample size.

Future Direction:

Future studies can be undertaken with large sample size to determine the changes in belief of medical students admitted year 2019 onwards.

Acknowledgement:

Our sincere thanks to Dr. Manoj Jani and all participants.

Abstract

Background: Drug abuse affects the health and lives of millions of individuals across the world. Discrimination faced by substance users and stigmatization becomes a barrier for them thus these patients do not receive the required care and treatment they deserve. The negative perception of healthcare professionals leads to poor therapeutic alliance between them and the patients of substance use. Current study aims to determine and assess the attitudes of the health professionals towards patients with substance use problems and to identify factors causing diverse attitudes of health professionals towards these patients.

Method:A questionnaire based cross sectional study was undertaken at Ananta hospital Rajsamand (a tertiary health care centre) which included 134 health professionals both doctor and nursing staff for a duration of one year who provided their consent for this project. The socio- demographic details of every participant was collected and all of them were given the DDPPQ tool which assessed their attitudes and perception towards drug and drug use problems.

Results: Younger age group of health professionals showed better outlook towards patients of drug abuse. A linear regression of gender, professional roles (i.e. doctors and nurses), past history of substance abuse and known history of substance abuser in the family with the principal component does not yield any significant results. Majority of the participants had either neutral opinion or positive opinion towards the problem of drug use and the drug users.

Conclusions: Healthcare professionals with age on the lower side had more positive regards and significantly positive attitudes towards the problems of substance use and therefore the

therapeutic compliance was better. Healthcare delivery needs unbiased and non-judgmental attitude of healthcare professionals towards patients of substance abuse, so in an attempt to provide holistic approach and care that overlooks socio-demographic and clinical profiles, professionals should have adequate and appropriate training and exposure accordingly.

Keywords: Professionals, nursing, staff, substance, drug, perception, attitudes, stigmatization.

Introduction

Drug abuse is a global phenomenon which affects almost every country with a variable extent. Abuse of illicit drug affects the health and lives of many individuals across the globe. The criminalization of this addictive behavior damages the reputation of the engaged person and it also deters other people, leading to stigmatization of the problem in the society. Stigmatization also discourages illicit drug users from getting health care due to fear of poor treatment by health care providers or fear of trouble with the authorities[1,2]. While stigma and discrimination may serve as deterrents to illicit drug use, these attitudes also contribute to discrimination and stigmatization experienced by illicit drug users which may be bad for drug user's health[3]. Negative attitudes of health professionals towards patients with an alcohol or other drug addiction are known to lead to poor communication between professional and patient, diminished therapeutic alliance, and mis-attribution of physical illness symptoms to substance use problems, also referred to as diagnostic overshadowing[4,5].

In this scenario, medical professionals are key persons in the provision of care for persons who exhibit problems related to use of the substances of abuse. Personal factors[6] and deficient medical education about addiction in health professionals[7] influence the under-diagnosis of substance abuse disorders. Studies have found that physicians were significantly less satisfied when caring for patients with drug problems compared to other illnesses[8]. A study on nurses found that nurses struggled with the care for patients who use illicit drugs and they had less motivation, satisfaction, role support and education[9]. Another study found that staff who had received training held fewer negative attitudes towards illicit substance users regardless of their length of clinical work experience or type of work setting[10]. Another study found that health professionals' regard was lowest for patients with drug and alcohol problems, lowest regard was found among physicians who did not work in specialized addiction services[11]. This study found that specially trained personnel's in this field such as psychologists, social workers, and professionals in the addiction services showed the highest regard while physicians who did not work in specialized addiction services had lowest regard. People with drug related disorders deserve the same level of care as patient with any other health condition. Health service need to be able to identify drug use and drug use disorder at an early stage and provide prevention, treatment and harm reduction intervention. We could not find any study in our region addressing health professional attitudes towards persons with problems related to substance use.

Aims and Objectives

Current study aims to assess and determine the attitudes of the health professionals

towards patients with substance use problems and to identify factors causing diverse attitudes of health professionals towards these patients.

Methods

Study area

The study was conducted at Ananta Hospital Rajsamand (attached to Ananta Institute of Medical Science and Research Centre, Rajsamand, Rajasthan) a tertiary care hospital.

Study Design

Questionnaire based cross sectional study

Study Participants

Health Professionals (Including doctors and nursing staff)

Study duration

One Year, September 2019 to August 2020.

Sample size

A total population of health care professional of 200 working in Ananta Institute of Medical Science and Research Centre, Rajsamand, Rajasthan, a tertiary care hospital. Minimum of 134 participants were expected to participate according to the following calculation.

$N^* = N*X / (X + N - 1)$,

where,

$$X = Z^2_{1-\alpha}\, p(1-P)/d^2$$

where alpha (α) = 0.05, estimated proportion (p) = 0.50, estimated error (d) = 0.05 and N is the population size

The Finite Population Correction is used to adjust a variance estimate when sampling without replacement.[15]

A stratified random sampling technique has been used for collection of data. A validated 22-item DDPPQ questionnaire tool has been used in the study.

Statistical analysis

Questionnaire data was analyzed using SPSS version 24. Socio demographic data were summarized using frequencies and percentages. Means and standard deviation were used for continuous variables. Mann Whitney U test was used to compare the difference among professional groups i.e. doctors and nurses. The relationship between DDPPQ scores and other relevant variables was analyzed by using Pearson Product-Moment Correlation Co-efficient. The regression analysis has been done to find out relationship between independent and dependent variables. Statistical significance was taken at the 5% level.

Data Collection Procedure

The 22-item validated version of Drug and Drug problems perception questionnaire (DDPPQ) instrument was used for the study[12]. The validated DDPPQ, comprises of 22 items and is a shorter questionnaire, having retained only the most reliable items from the original instrument. The items of the validated questionnaire are numbered consecutively from one to twenty-two. The validated DDPPQ is a self-complete 'paper and pencil' questionnaire. Respondents are asked to rate their level of agreement on a series of 22 statements about working with people who use licit or illicit drugs in a nontherapeutic way. There are seven possible responses to each item on a scale of Strongly agree' to 'Strongly disagree'. Low scores denote positive attitudes, whereas high scores are associated with negative views. Several of the items are worded negatively. These are Items 15, 16, 17 and 18. For the purpose of this study, the DDPPQ were expressed on a 5-point Likert scale ranging from 1 = strongly agree, 2 = agree, 3 =neither agree nor disagree, 4 = disagree to 5= strongly disagree

.A 5 - point Likert-type scale instead of 7-point was used to increase response rate and response quality along with reducing respondents' frustration level[13]. Factor structure of the validated DDPPQ has yielded its six factors which are role adequacy, motivation, role legitimacy, task specific self-esteem, role support and work satisfaction

Study Variables

The independent variables in the study are the socio-demographic characteristics of the study participants such as gender, age, profession, work motivation and role support of health professional. The dependent variables, attitude and perception are measured by six factors/ subscale measure (using 5- point Likert scale) in the DDPPQ. Questionnaire data was analyzed using SPSS version 24. Socio-demographic data were summarized using frequencies and percentages. Data was analyzed by using unrelated T-test, Mann Whitney U test and Pearson product moment correlation coefficient.

For the questionnaire survey, 22 items of validated version of DDPPQ questionnaire was distributed individually to the 152 professional group members in a sealed envelope and returned back in same sealed condition in order to maintain privacy of participants. One hundred and thirty-four participants returned the completely filled up questionnaire. All professional group members i.e. both doctors and nursing staff members responses to the given DDPPQ questionnaire were calculated to give a total attitude score. The minimum score for the DDPPQ is 22 and the maximum score is 110. The higher the score obtained indicates an increasingly more negative attitude.

Results

Table 1: gives description of number of participants according to the gender as well their professional roles.

Group	Number (Total=134)	Percentage
Doctors	85	63.4 %
Males	53	39.5 %
Females	32	23.8 %
Nursing staff	49	36.5 %
Males	30	22.3 %
Females	19	14.1 %

Table 1. Profile of the Sample

Table 2: shows profile of the sample according to professional group and gender.

	Number of responses	Score Range	Mean Score (SD)	Z score	P* Value
Doctors	85	24-76	49.63 (8.95)	-0.30	0.75
Nursing Staff	49	33-68	49.46 (9.52)		

Table 2. The DDPPQ Score Range for Professional Groups

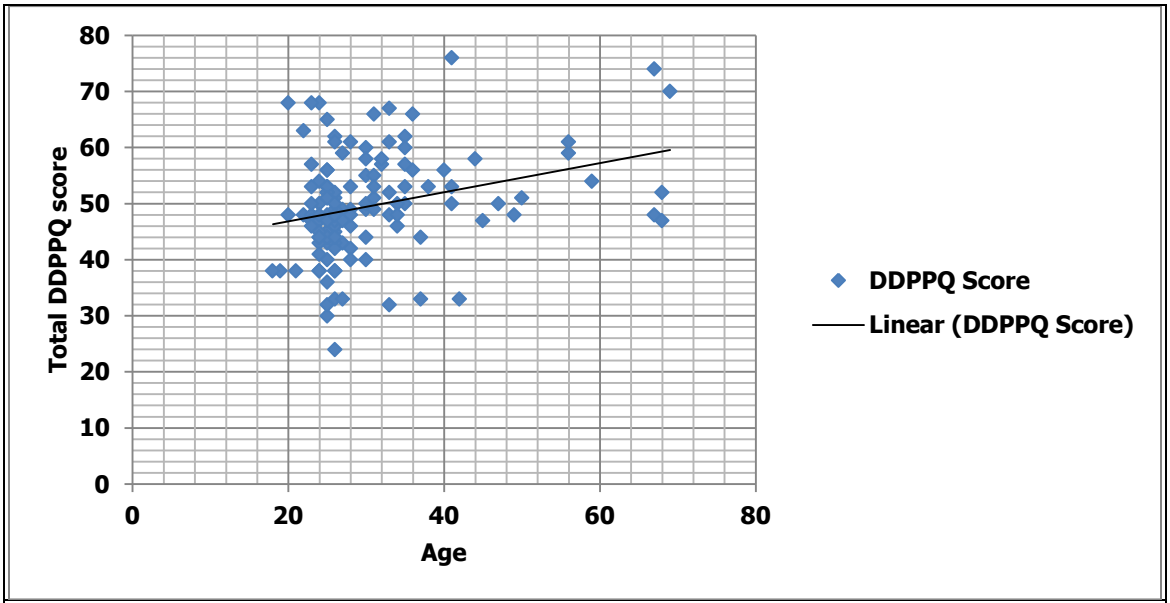
Mann Whitney U test. * The result is significant at $p<0.05$

Table 2 shows the DDPPQ score range for the participants. A Mann-Whitney U test was conducted to compare DDPPQ scores between doctor and nursing staff. The result is not significant at $p<0.05$. There is no difference between the groups.

Age of Participants Versus DDPPQ Score

Mean age of the total sample was 30.56 years (standard deviation 10.38). Mean age for doctors' group was 32.85 years (standard deviation= 11.86) and for nursing staff group was 26.59 years (standard deviation=5.21).

There is significant correlation between the age of the professional group members i.e., both doctors and nursing staff members and their respective DDPPQ scores when calculated using Pearson Product – Moment Correlation Co-efficient (2 tailed) $r = 0.29$, $n = 134$, $p = 0.00067$.



Graph 1: Distribution Graph of Age Versus Total DDPPQ Score

The graph indicates weak positive correlation between age of the participants and their corresponding DDPPQ score.

Family History versus DDPPQ Score

Participants were also asked if they had any family history of substance abuse and past history of substance abuse.

Table 3: Comparisons among Health Professional having Family History of Substance Abuse and Past History of Substance Abuse

	Response	Number of Responses	Range	Mean (Standard Deviation)	Z Score	p*Value
Family history of substance abuse	Positive	22	43-63	52.09(5.97)	-1.786	0.074
	Negative	112	24-76	49.08(9.57)		
Past history of substance abuse	Positive	23	38-65	50.17(7.16)	-0.393	0.694
	Negative	111	24-76	49.45 (9.51)		

Mann Whitney U test. * The result is significant at $p<0.05$

In Table 3, comparisons among Health professional having family history of substance abuse and past history of substance abuse are described. Using Mann- Whitney U test, we found that there is no statistical difference between the groups of health professional having past history of substance abuse and health professional who don't have past history of substance and the groups of health professional having family history of substance abuse and health professional who don't have family history of substance abuse.

A linear regression of gender, professional roles (i.e., doctors and nurses), past history of substance abuse and known history of substance abuser in the family with the principal component has not yielded any significant results.

Table 4: Health Professional Therapeutic Commitments towards Drug Abusing Patients on various Subscales of DDPPQ and total Mean Score

Subscales	Number of Questions	Mean Score Per Question (LikertScore = 1-5)	Standard Deviation
Role adequacy	8	1.99	0.65
Role Legitimacy	3	1.85	0.71
Role support	3	1.92	0.64
Work satisfaction	4	2.18	0.76
Motivation	1	3.58	1.17
Task specific Self Esteem	3	3.39	1.07
Total Score	22	49.57 (possible score 22-110)	9.13
Note: lower score denotes higher therapeutic commitment.			

Table – 4 shows a mean of total score of 49.57 (SD = 9.13) with a possible score between 22 and 110. **The diverse attitudes of Health Professionals towards substance abusers**

Table 5: Percentage of Participants in three Categories

	Frequency	Percentage
Positive [a]	36	26.86
Neutral [b]	91	67.92
Negative [c]	7	5.22
	134	100
a= Total score from 22 to 44; b) total score from 45 to 66; c) total score from 67 to 110		

The total DDPPQ scores were divided into three categories i.e. (1) Positive perception (distinctly defined perception of role), (2) Negative perception (lack of distinctly defined perception of role) and (3) neutral perception (neither distinctly defined perception of role nor lack of distinctly defined perception of role). The range for all three perceptions was determined by the possibility maximum and minimum score in 5 point- Likert scale. Table 5 shows percentage of participants in these three categories.

Discussion

Current study aimed to assess and determine the attitudes of health professionals towards patients with substance use problems in our region and to identify factors causing diverse attitudes of health professionals towards these patients. There was weak positive correlation between age of the participants and their

corresponding DDPPQ score that is older health professionals had relatively negative attitude. This was in contrast to a study that found that older nurses believed more strongly that alcoholism is an illness[14]. The two professionals' groups were assessed by comparing health professionals having family history of substance abuse and past history of substance abuse, and it was found that there is no statistical difference between the two groups of health professional. The mean DDPPQ score in these groups ranged towards lower side denoting positive attitude towards these patients, means their past or family history of substance use didn't significantly affect the attitude. Our study found that there was no statistically significant difference between the DDPPQ scores between the two groups i.e., doctors and nursing staff.

Considering all participants in a group, the lower skewed total mean DDPPQ score of 49.57 (SD = 9.13, with a possible score between 22 and 110) in our study correlated with a more positive attitude and higher therapeutic commitment to drug abusing patients. On mean Likert-format response per question (of 1= Strongly agree to 5= Strongly disagree), the highest therapeutic commitment is reflected in role legitimacy subscale which indicated the degree that professional group members felt that drug abuse history taking and counseling was a professional responsibility. Role support and Role adequacy followed the next which reflected that professional group members felt that they have adequate knowledge of drug and drug related challenges. Also whenever required, they will get support or help to resolve drug related problem. Highly skewed score in motivation and self-esteem subscale reflected lower therapeutic commitment. Role support, role adequacy, role legitimacy and work satisfaction were all somehow interconnected with each other at the basic level along with motivation and self-esteem to aid in understanding of the plight of patients of substance abuse and thereby providing therapeutic care and overall management to such patients. Our findings are in contrast to another study which found that healthcare providers struggled with the care for patients who used illicit drugs and they had less motivation, satisfaction, role support and education.[9]Crothers and Dorrian also found high scores regarding work satisfaction which indicated that nurses' attitudes regarding how much they like, and feel rewarded by, working with patients with alcohol problems, are an important determinant of the extent to which nurses are actually willing to engage in this work[15].

In an attempt to identify diverse attitudes of health professionals towards substance abusers, the sample participants were divided into three categories for ease of understanding - Positive perception, Negative perception and neutral perception; and it was found that number of healthcare professionals having neutral perception were maximum, followed by those having positive perception and least holding negative approach to the drug abuse patients. In a study nurses appeared to have, on average, attitudes that were consistently quite positive, if not neutral[14]. As healthcare professionals are the chief gatekeepers in the management of patients who suffer from substance use disorder, there is need of the hour to change both the neutral and negative attitude of the health care workers into positive attitude. To improve local services, Howard et al recommended that a training strategy should be developed with consideration to a structured programme covering all aspects of providing care to inpatients with co-occurring mental health and substance use problems; implementing training and support structures for staff will enable them to deliver more recovery and client centered interventions for patients with these co-occurring issues[10].

Healthcare delivery needs unbiased and non-judgmental attitude of healthcare professionals towards patients of substance abuse, so in an attempt to provide holistic approach and care that overlooks socio-demographic and clinical profiles, professionals should have adequate and appropriate training and exposure accordingly. We propose some ways that can be executed systematically to bring about the necessary change in the attitudes of a healthcare professional- First and foremost is sensitization of healthcare professionals (both the doctors as well as the nursing staff) which is primarily important to achieve better outcomes in management of patients of substance use disorders. Secondly, there are ways to be incorporated at the grass root level which directly and/or indirectly will have an impact on the management of such patients include: (i) training – providing education and skills to the professionals and conducting workshops at regular intervals, teaching institute – both the medical colleges and the nursing colleges are jointly responsible in training the students who take up this field and providing opportunities for them to learn,(ii) exposure – mandatory rotatory postings for every undergraduate medical/nursing student to understand patients from having them visit an addiction wing facility of outdoor and indoor patients run by the department of psychiatry at the institute where they come across such patients of substance abuse.

Conclusion

Our study found that the younger age group healthcare professionals had more positive outlook and attitude towards substance users. The lower skewed total mean score of participants denoted more positive attitude and higher therapeutic commitment. Subdivision of the participants in three groups to a step forward revealed that majority of them had either positive or neutral attitude towards patients with problem of substance abuse, leaving a minority or handful percentage of participants who had negative perception and attitude.

Implications of the Study

our study will help in identifying diverse attitude of health professional towards patients with substance use disorders and the associated factors. Awareness and proper education along with skills instilled among these healthcare professionals will strengthen the belief and trust of the patient receiving treatment and management during the prolonged period provided for deaddiction. The provision of adequate, timely guidance and motivation at every step to reduce the use of illicit substances, would help in controlling the menace of drug abuse can be well achieved.

Limitations

This was a cross sectional study with small sample size.

Future Direction

Future studies can be undertaken with large sample size to determine the changes in attitudes and knowledge of healthcare professionals prior to any kind of exposure or training received and followed up by assessing them after they have achieved skills, knowledge and training in the field of addiction psychiatry.

Acknowledgement

Our sincere thanks to Dr. Preeti Sharma and Dr. Harshul Bohra.

How Stigma and Discrimination are Perceived by Rural or Urban Patients Suffering from Schizophrenia? An Exploratory Cross – Sectional Study from Western India

Bharat Agarwal[1], Sunil Kumar[2*] and G.K. Vankar[3]

[1]Assistant Professor; [2]Senior Resident, Department of Psychiatry, Ananta Institute of Medical Sciences and Research Centre, Rajsamand. [3]Department of Psychiatry, GFC Dutta Meghe Institute of Medical Sciences University, Vardha.

Original Article

ABSTRACT

Background: *Stigma is conceptualized as an attribute which is deeply discrediting and makes the person carrying it different from other and of a less desirable kind. Current study aimed to describe the nature and direction of experienced stigma; and discrimination reported by people with schizophrenia.* ***Methods:*** *One hundred and fifty patients diagnosed with Schizophrenia were selected from the Out Patient service of Psychiatry Department of a medical college general hospital. The experiences of stigma and discrimination were assessed using a semi-structured instrument developed by national working group for India by the world psychiatric association steering committee.* ***Results****: Differences were seen between rural and urban respondents. Patients from rural background more often reported these experiences: society treats differently, ridiculing by others, offensive comments, hiding from relatives, rejecting attitude of peoples around, attribution of supernatural cause as most common source of stigma, social exploitation, not fully accepted in the family, pushed into unacceptable social situation and sexual harassment. Reported narratives provided the direct view of these patients.* ***Conclusions****: Stigma experience is pervasive: it deeply affects the social, occupational and emotional wellbeing of patients with schizophrenia and should be included in clinical management. Effective anti-stigma intervention should target on improving attitudes and the condition for social integration in the community, empowering people with schizophrenia to challenge self-stigmatization and discrimination behavior towards them.*

Key words: *Schizophrenia, Stigma, Discrimination, Experiences, Attitude.*

INTRODUCTION

Schizophrenia is the most debilitating chronic psychiatric disorder which usually affects adolescents and young adults, disrupting pursuit of their educational and occupational goals. The disorder is associated with significant stigma and discrimination, which further increase the burden on these patients and their families. The essence of stigma is a negative and prejudicial attitude toward someone with a mental illness. Many people with mental illness describe the effect of stigma as severe, and more difficult to deal with as compared to the mental health problem itself. Discrimination occurs when people with mental illness are treated unfairly, or are denied their rights because of their mental illness. Individuals with schizophrenia often face social isolation; discrimination in housing, education and employment opportunities, and other forms of prejudice.[1]The stigma often extends to family members and to those who provide health care services to patients with the disorder. Major international studies suggest that schizophrenia has better prognosis in low-income nations and in rural settings.[2-4] The industrialization hypothesis has been advanced to explain this differential outcome which argues that industrial economies and attendant life styles lead to poor support, intolerance, rejection, isolation, segregation and institutionalization of the severely mentally ill.[5] The value placed on the autonomous individual in industrialized settings therefore accentuates social extrusion of the chronic mentally ill patient who assumes personal responsibility for the illness. In consequence, prognosis worsens in urban industrialized settings.

Studies on stigma and mental illness in the Indian setting have focused both on measurements of stigma and on locally important socio-cultural factors shaping stigma.[6-9] Numerous other studies have addressed public attitudes

towards mental illness.[10-12] The nature, determinants, and consequences of stigma vary across culture and region. Hence, there is a need for studies to understand the stigma specific to a particular region to plan intervention. Better understanding and identification of determinants may suggest ways to reduce stigma and help prevent its adverse consequences.

With this background, this study was aimed to study stigma and discrimination perceived by patients with schizophrenia and, its comparison between rural and urban patients.

METHODS

2.1 Material

This was a cross sectional study conducted at psychiatry OPD of Civil hospital Ahmedabad, Gujarat. Clearance from the institutional review board was taken prior to conducting the study. The sample consisted of one hundred fifty patients diagnosed with schizophrenia independently by two psychiatrists as per criteria laid down by diagnostic and statistical manual (DSM IV-TR). Information from the caregivers and the patient case file along with a mental status examination also were used for diagnostic confirmation. The purpose of the study was explained to patients and their caregivers. The consent of the caregiver was also taken. The patients' responses were recorded.

2.2 Inclusion criteria:

1. A patient with a diagnosis of schizophrenia under continuous remission of at least six-month period according to DSM IV-TR criteria.
2. Provision of the consent.

2.3 Exclusion criteria:

1. Those patients with co-morbid axis I /II disorder.
2. The patient having co-existing medical or substance use disorder other than nicotine.

2.4 Instruments for the study

A semi structured interview developed in an earlier study.[13] This instrument has been used on over 1000 patient in four cities, as a part of the Indian initiative of the world psychiatric program to reduce the stigma and discrimination because of schizophrenia. It consists of two parts: first part of the scale elicits the socio-demographic information of the respondents while second part of the scale measures stigma and discrimination experiences including nature of stigma experiences, attitude of relatives, friends and caregiver, source of stigma, consequences of stigma, patient's view how stigma could be reduced and to what level, comparison of severity of mental illness to other medical illness bringing disability. The verbatim regarding patient's stigma experience in areas like personal, family, social, occupational and in marital life also were recorded.

2.5 Statistical analysis

Both quantitative and qualitative analysis were done using computer. The data from urban and rural areas were compared to find out any difference. Quantitative data was analyzed by t-test and chi-square test. The narratives were read to identify the themes of stigma. For natural and objective analyses, the data were coded manually into constructs that emphasized stigmatizing experiences in various spheres of patient's life.

RESULTS

3.1 Socio-demographic characteristics:

The table 1 shows socio-demographic characters of the sample (N=150).

As shown in Table 1, majority of the patients were male (64%), Hindu by religion (86.6%), of age range 21-30 years (42%), married (49.3%), educated up to class 10th (69.3%), living in a joint family (52%), unemployed (62%), having income under 1000 rupees per month (68%).

Disease related characteristics: Seventy-nine (52.6%) patients (rural=18, urban=61) were having paranoid subtype of the disorder. One hundred thirty-six (90.6%) patients (rural=36 and urban=100) were having duration of illness more than two years.

Table: 1 Demographic characteristic

S. No.	Sample (N=150)	Rural N=39 (26%)	Urban N=111 (74%)
1.	**Religion**		
	Hindu (130, 86.6%)	33 (84.6%)	96 (86.5%)

	>1000 (48, 32%)	08 (20.5%)	40 (36.0%)

Table 2 shows various stigma variables experienced by the patients.

Table 2: Common stigma experienced by patients

Variable	Rural N, (%)	Urban N, (%)	Chi square
Society treats differently	27(69.2%)	60 (54.0%)	X^2=2.73, df=1, p=0.09
Ridiculing by others	29(74.4)	67(60.4)	X^2=2.45, df=1, p=0.11
Offensive comments	30(76.9)	62(55.9)	X^2=5.40, df=1, p=0.02
Hide from relatives	26(56.7)	57(51.3)	X^2=2.74, df=1, p=0.09
Difficulty in getting marriage proposal	09(23.1)	36(32.4)	X^2=1.20, df=1, p=0.27

Table 3 shows various consequences of the stigma and discrimination experienced by the patients. Other findings of the study were as mentioned here. The most common reported source of stigma was attribution of supernatural cause in rural patients (41%) while in urban patients it was

not being able to work due to illness (39.6%). Avoidance was the most common attitude of relatives towards patients in both regions (51.2% rural, 41.4% urban).

Table 3: Consequences of the stigma and discrimination

Variable	Rural N, (%)	Urban N, (%)	Chi square
Avoid disclosing the mental illness histories in jobs/application	03 (7.69%)	21 (18.92%)	X^2=2.71, df=1, p =0.100
Social exploitation	25 (64.10%)	40(36.04%)	X^2=9.26, df=1, p=0.002
Not fully accepted in the family	29 (74.36%)	61 (54.95%)	X^2=4.53, DF=1, p=0.03
Pushed into unacceptable social situation	11 (28.2%)	15 (13.5%)	X^2=4.35, DF=1, p=0.04
Sexual harassment	14 (35.9%)	20 (18.0%)	X^2=5.26, DF=1, p=0.02
Living alone	24 (61.5%)	80 (72.1%)	X^2=1.5, DF=1, p=0.22

Friends and relative either stopped visiting at all or visited less frequently in rural patients (43.5%), while 42.3% urban patients reported that friends and relatives stopped visiting at all. In rural area, patients attributed their illness to faulty biological functioning (33.3%) while in urban area patients accepted that they are mentally ill (45.0%). Mental illness was reported as most disabling illness by 71.7% rural and 54.0% urban patients. Forty one percent rural patients while 34.2% urban patients reported that stigma can be partially cured. Involvement in advocacy activities was reported to be an effective strategy to reduce stigma by 64.2% rural and 55.8% urban patients. Most of the patients (94.8% rural and 77.4% urban) reported that concealing or selective disclosure of the illness is not an effective strategy to reduce stigma. Increasing awareness of the mental illnesses was reported to be an effective way to reduce stigma (69.2% rural, 65.7% urban).

Common stigmatizing verbatim reported by the patients:

I. Common stigmatizing verbatim reported by rural patients:

- "In the society, nobody enquires about me. Nobody loves me. Nobody even looks at me. They call me 'mad', and laugh at me. They don't even invite me at their home on festivals. Due to my illness, my marriage is not getting fixed."

-"In my village when houses were repaired, everybody got the letter but they didn't provide the same for met. Nobody wants to come and meet me. Today I have a broken house to stay pending repair work. I asked for help from my friends and relatives but nobody comes forward. Every times during rain, water comes into my house no body helps me."

II. Common stigmatizing verbatim reported by urban patients:

- "When I fell ill, everyone in my house kept nagging me all day. They didn't give me food. They used to beat me and threw me out of house, when I went to my mother's place, there also people used to nag me. In the beginning, my husband was cooperative, but now he doesn't talk to me much and does not maintain sexual relationship with me."

- "Neighbors don't talk to me. When I go to collect water in the morning, they keep on pushing me, they throw my vessels away. They abuse me and also hit me. My house owner keeps on telling me and my family members to vacant the house."

Consequences of Stigma

I. Experiences related to personal area:

- "I was bright in study prior to the illness, but I quitted my study as I failed in 10th. My memory power went down. My writing is also getting bad. I can't work at my home as I get tremor at my hand. I am unmarried yet, few relative come for my younger sister but when they knew about my illness, they went away."

II. Experiences related to Occupational area:

- "At my work place, people call me "mad". My boss gets angry on me every day and says that my head is empty. He always says me that they will sack me. At lunch hour I am not allowed to have lunch while everybody else is going for lunch. I get half the salary others get."

III. Experiences of stigma and discrimination in Social life:

- "I have one house with 2 BHK in Ahmedabad. When some relatives come to the city, though they stay at my house but nobody of them takes lunch or drinks water at my house. They stay only up to next morning and leave afterwards. Neighbors don't talk to me. They said me that I am mad. They give me work always without giving me any money, and upon asking, they refuse for the money."

- "Before illness, I was living in rented house. I was an inspector in IT department. People used to meet me and respect me, but when owner of the house knew about my illness, he asked me to vacate his house. Today I am living in small house alone. People avoid me."

IV. Experiences related to marital life:

- "Because of illness I am not able to work in my land. My land remains uncultivated. My desire for sex has come to an end. My penis is not erectile any more. Due to this, my wife left me and went to her parents place. Today she has got married to another person."

- "I was married in great pomp. My mental illness started at my in laws place. Initially they used to beat me a lot, they took me to a faith healer, after that they left me to my mother's place. My mother tried for many attempts one after another for my marriage. Every time, as my wife knew about my illness, she divorced me."

V. Experiences of stigma and discrimination in Family:

- "I had to hide my illness because mine and my sister's marriage were at stake. I got married in far Village, but when knew about my illness, they sent back me to my maternal home. I was pregnant at that time. After delivery, they called me back but when I was breast feeding my baby, my mother in law took my baby away and told, "You are mental and the child will also become mental if you breast feed the baby."

- "Nobody takes care of me at home even if I am ill and I need medication regarding this. When I told my brother and father about this, so they became angry on me and said you are mad, go wherever you want to, we do not have time for you"

VI. Impact of illness on General Life

a. Hiding of illness:

- "I have to stay in my house all day hiding my illness. Whenever I come at the window, my mother gets angry on me and directs me to go inside. She tells me that if people will know about my illness then nobody will marry me and my sister."

b. Decrease in Work efficiency and cognitive function:

- "Welding was my profession earlier but today I cannot concentrate on my work properly. I have been injured also because of this."

c. Visiting of Friends and Relative:

- "Since the starting of my illness, people are scared of me and they don't come near me. I had to live alone at home."

d. People's reaction after knowing their illness:

- "If any one comes from my family, they talk only one thing, to take medicine but nobody talks to me more than this. I have to live alone."

e. Most Disabling Illness:

- "Mental health problems should not occur. It becomes difficult to work. I am feeling better till I take medicine but my memory is decreasing. Nothing is remembered. I have to take pills to sleep in night."

DISCUSSION

The present study was aimed to study stigma and discrimination perceived by patients with schizophrenia and, its comparison between rural and urban patients. Majority of the patients were male, Hindu by religion, of age range 21-30 years, married, educated up to class 10th, living in a joint family, unemployed, having income under 1000 rupees per month. Findings of present study revealed that patients from rural background had more often stigmatizing and discriminating experiences compared to patients from urban background.

In our study, 62% patients were unemployed. Due to unemployment and chronic nature of illness, patients are not able to do their work as efficient as of their same age group in the society, which becomes the main culprit associated to creation of stigma. Stigmatization in the workplace and the related denial of access to job are the most important experiences of social exclusion. These experiences are recognized as the main factors producing and maintaining a high rate of unemployment among those with schizophrenia. In our study too, 21 (18.9%) urban and 3 (7.6%) rural patients reported avoiding disclosure of mental illness histories in job/applications.

In the present study, patients from rural background more often reported these experiences: society treats differently (p=0.09), ridiculing by others (p=0.11), offensive comments (p=0.02), hiding from relatives (p=0.09). Jadhav S et al also reported that rural Indians show significantly higher stigma scores.[14] Similar to our study an Indian study by Loganathan S et al reported that rural respondents experience more ridicule, shame, and discrimination but they reported that urban respondents feel the need to hide their illness.[15] Fear of rejection may be a need to hide their illness from others particularly in rural areas. In our study, more urban patients reported difficulty in getting married compared to rural patients (p=0.1). Weiss et al,[16] studying psychiatric stigma across cultures, pointed out that "in Bangalore the main concerns the sample had, were related to lowering their own chance of entering a good marriage and decreasing the chance of one of their relatives". Disclosing the diagnosis of schizophrenia becomes stigmatizing due to fear of being ridiculed, discriminated, leading to loss of job or not being able to get a job, and difficulty in getting married for the patient as well as family members. So, family members handle with it by hiding the diagnosis or not disclosing the presence of illness.

In our study, more rural patients reported social exploitation (p=0.002), not fully accepted in the family (p=0.03), pushed into unacceptable social situation (p=0.04), and sexual harassment (p=0.02) as a consequence of stigma and discrimination compared to urban patients. Jadhav et al also found that rural Indians showed a more stigmatizing attitude towards severe mental illness. Their study also showed greater stigma and a punitive attitude amongst rural Indians as compared to urban Indians.

In our study, rural patients reported attribution of supernatural cause as the most common source of stigma. Studies support this finding that in rural areas, the frequent association of mental illness with malevolent spiritual forces induces many families with a member with mental illness to seek help from shamans.[17,18] In rural areas, lack of adequate education regarding mental illnesses leads to such beliefs. Jadhav et al also concluded that urban Indians have a more liberal and tolerant attitude but were also more excluding of those with mental illness at work.[14] In our study too, not being able to work due to illness was the most common reported source of stigma in urban patients (39.6%).

In our study, rural patients reported rejecting attitude of peoples around while urban patients reported nagging and uncooperative attitude of the family members and society. Stigma led to painful experiences related to patient's personal and occupational area, social life, marital and family life. Fact of hiding the diagnosis of schizophrenia was also reported by the patients. Resulted decrease in cognitive functioning and impaired work efficiency also was reported by the subjects. The extent of the discrimination due to the illness resulted in stopped or less frequent visiting of the friends and relatives to the patients. The people around made either limited or no communication with the patients. Patients reported schizophrenia as the most disabling illness of all the illnesses.

Lack of correct knowledge is the variable associated with more stigma responses. Setting up programs directed towards modifying the attitudes of employers, as well as greater attention to the employment-related training of social workers could constitute useful instruments to improve labor market access for people with schizophrenia. These programs should help convincing employers that people with schizophrenia are highly motivated and can provide important contributions. At the same time, people with schizophrenia might need specific support in re-entering the labor market, such as Individual Placement and Support (ISP) Programs [19, 20]. Better integration in the labor market has been shown to improve clinical outcome[21-23] and reduce the risk of hospitalization.[24]

Stigma and negative public attitudes for a patient with schizophrenia is widely prevalent both in rural as well as urban areas. Therefore, while patients continue to consider stigma as a central obstacle to their integration into the community, they themselves contribute to this process by accepting public stereotypes as applicable to themselves. As a result, majority of them don't confront negative reaction, and lose self-esteem, isolate themselves and get worse. Our data from patient verbatim also highlighted that patient focus on the stigmatization experiences and on their ideas of the cause of stigma; while hardly offering any suggestions for anti-stigma intervention. Suggestion of participant mainly concerned the improvement of information on mental health issues among the public (66.7%). Participant did not seem to envisage many opportunities for positive change and found it difficult to formulate specific proposal on what could be done to improve their situation. Sorting out this difficulty might help reducing perceived stigma, discrimination and their consequences. Spending more time with a patient, may reduce stigmatizing and discriminating attitude presumably through the mechanism of exposure induced reduction of negative stereotype about the mental illness. Alexander & Link concluded that increasing personal contact with psychiatric patient could reduce people's stigmatizing

attitudes.[25] Couture & Penn also concluded that both retrospective and prospective contact tends to reduce stigmatizing views of persons with a mental illness.[26] Our findings suggest that people with schizophrenia are not fully accepted in the family, especially in rural areas. This suggests that certain factor could be more powerful than negative stereotypes in interpersonal stigmatization which can be overcome by provision of the scientific knowledge of the mental illnesses and re-integration of the patient in the community through psychosocial approaches.

Similar to our findings, Chinese families too, frequently concealed the mental illness of their members.[27] Family members act as both stigmatizer as well as victim of stigmatization themselves.[28] Because of this paradoxical role dualism, family members might project their anger towards a patient for causing them added suffering. This negative affective state, we suspect, could heighten the chronic burden of care. Providing adequate non-pharmacological measures may help family members in such circumstances of negative affective state. Provision of psychiatric care must move beyond symptoms control to diminish intentional as well as subtle forms of stigmatization in the patients' social life. Effective anti-stigma intervention should target on improving attitudes and the condition for social integration in the community, empowering people with schizophrenia to challenge self-stigmatization and discrimination behavior towards them. Regarding the work-related stigma, we believe that a combination of corporate education programme, legal measures and advocacy efforts are needed.

CONCLUSION

Stigma experience is pervasive: it deeply affects the social, occupational and emotional wellbeing of patients with schizophrenia and should be included in clinical management. Higher level of stigma is related to low education level, unemployment status. The provision of accurate information through trusted community sources and open dialogue may help to dispel myths, correct faulty assumption and increase the involvement of participation of community in dragging out the root source of stigma. Family programmes should be started early in an attempt to reduce stigma from significant others and to transform the family into a long recourse for psychiatric rehabilitation. Effective anti-stigma intervention should address chiefly two targets: improving attitudes and condition for social integration in the community and; empowering patients with schizophrenia to challenge self-stigmatization and discriminatory behavior towards them.

INTRODUCTION

Schizophrenia is the most debilitating chronic psychiatric disorder which usually affects adolescents and young adults, disrupting pursuit of their educational and occupational goals. The disorder is associated with significant stigma and discrimination, which further increase the burden on these patients and their families. The essence of stigma is a negative and prejudicial attitude toward someone with a mental illness. Many people with mental illness describe the effect of stigma as severe, and more difficult to deal with as compared to the mental health problem itself. Discrimination occurs when people with mental illness are treated unfairly, or are denied their rights because of their mental illness. Individuals with schizophrenia often face social isolation; discrimination in housing, education and employment opportunities, and other forms of prejudice.[1]The stigma often extends to family members and to those who provide health care services to patients with the disorder. Major international studies suggest that schizophrenia has better prognosis in low-income nations and in rural settings.[2-4] The industrialization hypothesis has been advanced to explain this differential outcome which argues that industrial economies and attendant life styles lead to poor support, intolerance, rejection, isolation, segregation and institutionalization of the severely mentally ill.[5] The value placed on the autonomous individual in industrialized settings therefore accentuates social extrusion of the chronic mentally ill patient who assumes personal responsibility for the illness. In consequence, prognosis worsens in urban industrialized settings.

Studies on stigma and mental illness in the Indian setting have focused both on measurements of stigma and on locally important socio-cultural factors shaping stigma.[6-9] Numerous other studies have addressed public attitudes

towards mental illness.[10-12] The nature, determinants, and consequences of stigma vary across culture and region. Hence, there is a need for studies to understand the stigma specific to a particular region to plan intervention. Better understanding and identification of determinants may suggest ways to reduce stigma and help prevent its adverse consequences.

With this background, this study was aimed to study stigma and discrimination perceived by patients with schizophrenia and, its comparison between rural and urban patients.

METHODS

2.1 Material

This was a cross sectional study conducted at psychiatry OPD of Civil hospital Ahmedabad, Gujarat. Clearance from the institutional review board was taken prior to conducting the study. The sample consisted of one hundred fifty patients diagnosed with schizophrenia independently by two psychiatrists as per criteria laid down by diagnostic and statistical manual (DSM IV-TR). Information from the caregivers and the patient case file along with a mental status examination also were used for diagnostic confirmation. The purpose of the study was explained to patients and their caregivers. The consent of the caregiver was also taken. The patients' responses were recorded.

2.2 Inclusion criteria:

1. A patient with a diagnosis of schizophrenia under continuous remission of at least six-month period according to DSM IV-TR criteria.
2. Provision of the consent.

2.3 Exclusion criteria:

1. Those patients with co-morbid axis I /II disorder.
2. The patient having co-existing medical or substance use disorder other than nicotine.

2.4 Instruments for the study

A semi structured interview developed in an earlier study.[13] This instrument has been used on over 1000 patient in four cities, as a part of the Indian initiative of the world psychiatric program to reduce the stigma and discrimination because of schizophrenia. It consists of two parts: first part of the scale elicits the socio-demographic information of the respondents while second part of the scale measures stigma and discrimination experiences including nature of stigma experiences, attitude of relatives, friends and caregiver, source of stigma, consequences of stigma, patient's view how stigma could be reduced and to what level, comparison of severity of mental illness to other medical illness bringing disability. The verbatim regarding patient's stigma experience in areas like personal, family, social, occupational and in marital life also were recorded.

2.5 Statistical analysis

Both quantitative and qualitative analysis were done using computer. The data from urban and rural areas were compared to find out any difference. Quantitative data was analyzed by t-test and chi-square test. The narratives were read to identify the themes of stigma. For natural and objective analyses, the data were coded manually into constructs that emphasized stigmatizing experiences in various spheres of patient's life.

RESULTS

3.1 Socio-demographic characteristics:

The table 1 shows socio-demographic characters of the sample (N=150).

As shown in Table 1, majority of the patients were male (64%), Hindu by religion (86.6%), of age range 21-30 years (42%), married (49.3%), educated up to class 10th (69.3%), living in a joint family (52%), unemployed (62%), having income under 1000 rupees per month (68%).

Disease related characteristics: Seventy-nine (52.6%) patients (rural=18, urban=61) were having paranoid subtype of the disorder. One hundred thirty-six (90.6%) patients (rural=36 and urban=100) were having duration of illness more than two years.

Table: 1 Demographic characteristic

S. No.	Sample (N=150)	Rural N=39 (26%)	Urban N=111 (74%)
1.	**Religion**		
	Hindu (130, 86.6%)	33 (84.6%)	96 (86.5%)
	Muslim (17, 11.3%)	05 (12.8%)	12 (10.8%)
	Others (3, 2%)	01 (2.5%)	03 (2.7%)
2.	**Gender**		
	Male (96, 64%)	23 (59%)	73 (65.8%)
	Female (54, 36%)	16 (41%)	38 (34.2%)
3.	**Age (years)**		
	21-30 (63, 42%)	20 (51.2%)	39 (35.1%)
	31-40(42, 28%)	08 (20.5%)	34 (30.6%)
	41-50 (28, 18.6%)	09 (23.0%)	19 (17.2%)

Table 2 shows various stigma variables experienced by the patients.

Table 2: Common stigma experienced by patients

Variable	Rural N, (%)	Urban N, (%)	Chi square
Society treats differently	27(69.2%)	60 (54.0%)	X^2=2.73, df=1, p=0.09
Ridiculing by others	29(74.4)	67(60.4)	X^2=2.45, df=1, p=0.11
Offensive comments	30(76.9)	62(55.9)	X^2=5.40, df=1, p=0.02
Hide from relatives	26(56.7)	57(51.3)	X^2=2.74, df=1, p=0.09
Difficulty in getting marriage proposal	09(23.1)	36(32.4)	X^2=1.20, df=1, p=0.27

Table 3 shows various consequences of the stigma and discrimination experienced by the patients. Other findings of the study were as mentioned here. The most common reported source of stigma was attribution of supernatural cause in rural patients (41%) while in urban patients it was

not being able to work due to illness (39.6%). Avoidance was the most common attitude of relatives towards patients in both regions (51.2% rural, 41.4% urban).

Table 3: Consequences of the stigma and discrimination

Variable	Rural N, (%)	Urban N, (%)	Chi square
Avoid disclosing the mental illness histories in jobs/application	03 (7.69%)	21 (18.92%)	X^2=2.71, df=1, p =0.100
Social exploitation	25 (64.10%)	40(36.04%)	X^2=9.26, df=1, p=0.002
Not fully accepted in the family	29 (74.36%)	61 (54.95%)	X^2=4.53, DF=1, p=0.03
Pushed into unacceptable social situation	11 (28.2%)	15 (13.5%)	X^2=4.35, DF=1, p=0.04
Sexual harassment	14 (35.9%)	20 (18.0%)	X^2=5.26, DF=1, p=0.02
Living alone	24 (61.5%)	80 (72.1%)	X^2=1.5, DF=1, p=0.22

Friends and relative either stopped visiting at all or visited less frequently in rural patients (43.5%), while 42.3% urban patients reported that friends and relatives stopped visiting at all. In rural area, patients attributed their illness to faulty biological functioning (33.3%) while in urban area patients accepted that they are mentally ill (45.0%). Mental illness was reported as most disabling illness by 71.7% rural and 54.0% urban patients. Forty one percent rural patients while 34.2% urban patients reported that stigma can be partially cured. Involvement in advocacy activities was reported to be an effective strategy to reduce stigma by 64.2% rural and 55.8% urban patients. Most of the patients (94.8% rural and 77.4% urban) reported that concealing or selective disclosure of the illness is not an effective strategy to reduce stigma. Increasing awareness of the mental illnesses was reported to be an effective way to reduce stigma (69.2% rural, 65.7% urban).

Common stigmatizing verbatim reported by the patients:

I. Common stigmatizing verbatim reported by rural patients:

- "In the society, nobody enquires about me. Nobody loves me. Nobody even looks at me. They call me 'mad', and laugh at me. They don't even invite me at their home on festivals. Due to my illness, my marriage is not getting fixed."

-"In my village when houses were repaired, everybody got the letter but they didn't provide the same for met. Nobody wants to come and meet me. Today I have a broken house to stay pending repair work. I asked for help from my friends and relatives but nobody comes forward. Every times during rain, water comes into my house no body helps me."

II. Common stigmatizing verbatim reported by urban patients:

- "When I fell ill, everyone in my house kept nagging me all day. They didn't give me food. They used to beat me and threw me out of house, when I went to my mother's place, there also people used to nag me. In the beginning, my husband was cooperative, but now he doesn't talk to me much and does not maintain sexual relationship with me."

- "Neighbors don't talk to me. When I go to collect water in the morning, they keep on pushing me, they throw my vessels away. They abuse me and also hit me. My house owner keeps on telling me and my family members to vacant the house."

Consequences of Stigma

I. Experiences related to personal area:

- "I was bright in study prior to the illness, but I quitted my study as I failed in 10th. My memory power went down. My writing is also getting bad. I can't work at my home as I get tremor at my hand. I am unmarried yet, few relative come for my younger sister but when they knew about my illness, they went away."

II. Experiences related to Occupational area:

- "At my work place, people call me "mad". My boss gets angry on me every day and says that my head is empty. He always says me that they will sack me. At lunch hour I am not allowed to have lunch while everybody else is going for lunch. I get half the salary others get."

III. Experiences of stigma and discrimination in Social life:

- "I have one house with 2 BHK in Ahmedabad. When some relatives come to the city, though they stay at my house but nobody of them takes lunch or drinks water at my house. They stay only up to next morning and leave afterwards. Neighbors don't talk to me. They said me that I am mad. They give me work always without giving me any money, and upon asking, they refuse for the money."

- "Before illness, I was living in rented house. I was an inspector in IT department. People used to meet me and respect me, but when owner of the house knew about my illness, he asked me to vacate his house. Today I am living in small house alone. People avoid me."

IV. Experiences related to marital life:

- "Because of illness I am not able to work in my land. My land remains uncultivated. My desire for sex has come to an end. My penis is not erectile any more. Due to this, my wife left me and went to her parents place. Today she has got married to another person."

- "I was married in great pomp. My mental illness started at my in laws place. Initially they used to beat me a lot, they took me to a faith healer, after that they left me to my mother's place. My mother tried for many attempts one after another for my marriage. Every time, as my wife knew about my illness, she divorced me."

V. Experiences of stigma and discrimination in Family:

- "I had to hide my illness because mine and my sister's marriage were at stake. I got married in far Village, but when knew about my illness, they sent back me to my maternal home. I was pregnant at that time. After delivery, they called me back but when I was breast feeding my baby, my mother in law took my baby away and told, "You are mental and the child will also become mental if you breast feed the baby."

- "Nobody takes care of me at home even if I am ill and I need medication regarding this. When I told my brother and father about this, so they became angry on me and said you are mad, go wherever you want to, we do not have time for you"

VI. Impact of illness on General Life

a. Hiding of illness:

- "I have to stay in my house all day hiding my illness. Whenever I come at the window, my mother gets angry on me and directs me to go inside. She tells me that if people will know about my illness then nobody will marry me and my sister."

b. Decrease in Work efficiency and cognitive function:

- "Welding was my profession earlier but today I cannot concentrate on my work properly. I have been injured also because of this."

c. Visiting of Friends and Relative:

- "Since the starting of my illness, people are scared of me and they don't come near me. I had to live alone at home."

d. People's reaction after knowing their illness:

- "If any one comes from my family, they talk only one thing, to take medicine but nobody talks to me more than this. I have to live alone."

e. Most Disabling Illness:

- "Mental health problems should not occur. It becomes difficult to work. I am feeling better till I take medicine but my memory is decreasing. Nothing is remembered. I have to take pills to sleep in night."

DISCUSSION

The present study was aimed to study stigma and discrimination perceived by patients with schizophrenia and, its comparison between rural and urban patients. Majority of the patients were male, Hindu by religion, of age range 21-30 years, married, educated up to class 10th, living in a joint family, unemployed, having income under 1000 rupees per month. Findings of present study revealed that patients from rural background had more often stigmatizing and discriminating experiences compared to patients from urban background.

In our study, 62% patients were unemployed. Due to unemployment and chronic nature of illness, patients are not able to do their work as efficient as of their same age group in the society, which becomes the main culprit associated to creation of stigma. Stigmatization in the workplace and the related denial of access to job are the most important experiences of social exclusion. These experiences are recognized as the main factors producing and maintaining a high rate of unemployment among those with schizophrenia. In our study too, 21 (18.9%) urban and 3 (7.6%) rural patients reported avoiding disclosure of mental illness histories in job/applications.

In the present study, patients from rural background more often reported these experiences: society treats differently (p=0.09), ridiculing by others (p=0.11), offensive comments (p=0.02), hiding from relatives (p=0.09). Jadhav S et al also reported that rural Indians show significantly higher stigma scores.[14] Similar to our study an Indian study by Loganathan S et al reported that rural respondents experience more ridicule, shame, and discrimination but they reported that urban respondents feel the need to hide their illness.[15] Fear of rejection may be a need to hide their illness from others particularly in rural areas. In our study, more urban patients reported difficulty in getting married compared to rural patients (p=0.1). Weiss et al,[16] studying psychiatric stigma across cultures, pointed out that "in Bangalore the main concerns the sample had, were related to lowering their own chance of entering a good marriage and decreasing the chance of one of their relatives". Disclosing the diagnosis of schizophrenia becomes stigmatizing due to fear of being ridiculed, discriminated, leading to loss of job or not being able to get a job, and difficulty in getting married for the patient as well as family members. So, family members handle with it by hiding the diagnosis or not disclosing the presence of illness.

In our study, more rural patients reported social exploitation (p=0.002), not fully accepted in the family (p=0.03), pushed into unacceptable social situation (p=0.04), and sexual harassment (p=0.02) as a consequence of stigma and discrimination compared to urban patients. Jadhav et al also found that rural Indians showed a more stigmatizing attitude towards severe mental illness. Their study also showed greater stigma and a punitive attitude amongst rural Indians as compared to urban Indians.

In our study, rural patients reported attribution of supernatural cause as the most common source of stigma. Studies support this finding that in rural areas, the frequent association of mental illness with malevolent spiritual forces induces many families with a member with mental illness to seek help from shamans.[17,18] In rural areas, lack of adequate education regarding mental illnesses leads to such beliefs. Jadhav et al also concluded that urban Indians have a more liberal and tolerant attitude but were also more excluding of those with mental illness at work.[14] In our study too, not being able to work due to illness was the most common reported source of stigma in urban patients (39.6%).

In our study, rural patients reported rejecting attitude of peoples around while urban patients reported nagging and uncooperative attitude of the family members and society. Stigma led to painful experiences related to patient's personal and occupational area, social life, marital and family life. Fact of hiding the diagnosis of schizophrenia was also reported by the patients. Resulted decrease in cognitive functioning and impaired work efficiency also was reported by the subjects. The extent of the discrimination due to the illness resulted in stopped or less frequent visiting of the friends and relatives to the patients. The people around made either limited or no communication with the patients. Patients reported schizophrenia as the most disabling illness of all the illnesses.

Lack of correct knowledge is the variable associated with more stigma responses. Setting up programs directed towards modifying the attitudes of employers, as well as greater attention to the employment-related training of social workers could constitute useful instruments to improve labor market access for people with schizophrenia. These programs should help convincing employers that people with schizophrenia are highly motivated and can provide important contributions. At the same time, people with schizophrenia might need specific support in re-entering the labor market, such as Individual Placement and Support (ISP) Programs [19, 20]. Better integration in the labor market has been shown to improve clinical outcome[21-23] and reduce the risk of hospitalization.[24]

Stigma and negative public attitudes for a patient with schizophrenia is widely prevalent both in rural as well as urban areas. Therefore, while patients continue to consider stigma as a central obstacle to their integration into the community, they themselves contribute to this process by accepting public stereotypes as applicable to themselves. As a result, majority of them don't confront negative reaction, and lose self-esteem, isolate themselves and get worse. Our data from patient verbatim also highlighted that patient focus on the stigmatization experiences and on their ideas of the cause of stigma; while hardly offering any suggestions for anti-stigma intervention. Suggestion of participant mainly concerned the improvement of information on mental health issues among the public (66.7%). Participant did not seem to envisage many opportunities for positive change and found it difficult to formulate specific proposal on what could be done to improve their situation. Sorting out this difficulty might help reducing perceived stigma, discrimination and their consequences. Spending more time with a patient, may reduce stigmatizing and discriminating attitude presumably through the mechanism of exposure induced reduction of negative stereotype about the mental illness. Alexander & Link concluded that increasing personal contact with psychiatric patient could reduce people's stigmatizing

attitudes.[25] Couture & Penn also concluded that both retrospective and prospective contact tends to reduce stigmatizing views of persons with a mental illness.[26] Our findings suggest that people with schizophrenia are not fully accepted in the family, especially in rural areas. This suggests that certain factor could be more powerful than negative stereotypes in interpersonal stigmatization which can be overcome by provision of the scientific knowledge of the mental illnesses and re-integration of the patient in the community through psychosocial approaches.

Similar to our findings, Chinese families too, frequently concealed the mental illness of their members.[27] Family members act as both stigmatizer as well as victim of stigmatization themselves.[28] Because of this paradoxical role dualism, family members might project their anger towards a patient for causing them added suffering. This negative affective state, we suspect, could heighten the chronic burden of care. Providing adequate non-pharmacological measures may help family members in such circumstances of negative affective state. Provision of psychiatric care must move beyond symptoms control to diminish intentional as well as subtle forms of stigmatization in the patients' social life. Effective anti-stigma intervention should target on improving attitudes and the condition for social integration in the community, empowering people with schizophrenia to challenge self-stigmatization and discrimination behavior towards them. Regarding the work-related stigma, we believe that a combination of corporate education programme, legal measures and advocacy efforts are needed.

CONCLUSION

Stigma experience is pervasive: it deeply affects the social, occupational and emotional wellbeing of patients with schizophrenia and should be included in clinical management. Higher level of stigma is related to low education level, unemployment status. The provision of accurate information through trusted community sources and open dialogue may help to dispel myths, correct faulty assumption and increase the involvement of participation of community in dragging out the root source of stigma. Family programmes should be started early in an attempt to reduce stigma from significant others and to transform the family into a long recourse for psychiatric rehabilitation. Effective anti-stigma intervention should address chiefly two targets: improving attitudes and condition for social integration in the community and; empowering patients with schizophrenia to challenge self-stigmatization and discriminatory behavior towards them.

Abstract

Objective: The objective of this study was to determine any association of age at onset (AAO) with clinical presentation of bipolar disorder (BD) and family history of illness. **Materials and Methods:** A hospital-based cross-sectional observational study was conducted including 162 patients having a diagnosis of BD current episode manic. Individuals were divided into three subgroups according to AAO, i.e., early-onset BD (EOBD) (AAO ≤21 years), intermediate-onset BD (AAO – 22–34 years), and late-onset BD (AAO ≥35 years). The subgroups were compared on clinical variables; items of the Young Mania Rating Scale (YMRS), Hamilton Depression Rating Scale (HAM-D), and Scale for the Assessment of Positive Symptoms (SAPS); and family history of illness. **Results:** The early-onset group had significantly more episodes per year than the other groups ($P < 0.001$). The prevalence of family history of mood disorder was also significantly higher in the early-onset group than the other subgroups. AAO was found to be significantly associated with different items of YMRS, HAM-D, and SAPS. The early-onset group had higher rating on irritability, motor activity–energy, sexual interest, depressed mood, delusions, and thought disorders, whereas the late-onset group had higher rating on elevated mood. **Conclusion:** EOBD can be considered as a specific phenotype of BD, which is more homogenous, severe, and inheritable form of illness.

Full Text

Bipolar disorder (BD) is a chronic mental disorder characterized by alternating episodes of depression, euthymia, (hypo) mania, and mixed states.[1] The usual age of onset of BD is before 30 years, and almost 90% of patients have onset before 50 years of age.[2],[3] BD has been reported to have a genetic basis with heritability of at least 60%–85%.[4],[5] A number of studies have attempted to identify the susceptibility loci adding evidence of linkage in multiple genomic regions.[6] However, these genetic studies have given conflicting results; which may be due to the lack of consensus regarding the proper definition of the affected phenotype and the questionable homogeneity of bipolar illness.[4],[5],[6] Thus, attention is shifting toward the study of clinical indicators of BD that are familial and may be useful for identifying inheritable forms of the illness.

Classifications such as the Diagnostic and Statistical Manual of Mental Disorders-5 defined certain specifiers of BD that have proven phenomenological relevance.[7] However, most are of limited utility in identifying homogeneous subgroups. There is a necessity to identify reliably defined clinical features that are clinically valid and associated with underlying genetic process. These features can help in identifying genotypes and making informed treatment decisions.[8]

There is considerable evidence to suggest that the clinical expression of BD differs according to age at onset (AAO), which has therefore been identified as a potential specifier of interest, especially patients having early onset of illness have specific clinical features and outcomes different from those of later onset of illness.[8],[9],[10] In this regard, multiple admixture studies have revealed that such patients could be categorized into three homogeneous subgroups (early-onset BD [EOBD], intermediate-onset BD [IOBD], and late-onset BD [LOBD]).[11],[12],[13],[14],[15],[16],[17],[18]

By making subgroups based on these cutoff points, the present study was aimed to compare the clinical presentation using the items of the Young Mania Rating Scale (YMRS), Hamilton Depression Rating Scale (HAM-D), and Scale for the Assessment of Positive Symptoms (SAPS) and to compare the presence of family history of the illness in Indian population. Such subgrouping may help in identifying phenotypes among BD patients.

Materials and Methods

A hospital-based cross-sectional observational study was conducted at the psychiatry department of the tertiary care hospital of western India. The study was conducted over a period extending from June 2018 to December 2018. Ethical clearance was taken from the research review board and ethical committee of the institution. Informed written consent was obtained from all the legal guardians of participants before inclusion in the study.

A consecutive sample of 162 patients admitted to the inpatient department with a diagnosis of BD current episode manic (as per the Diagnostic and Statistical Manual of Mental Disorders-5 criterion) was included in the study. The diagnosis was confirmed by applying the Mini-International Neuropsychiatric Interview (MINI).[19] Patients with history of intake of any psychiatric medicine in the last 2 weeks were excluded from the study because it can alter the severity of the symptoms. Patients suffering from mental retardation, dementia, comorbid psychiatric and substance-related disorder (as confirmed by using the MINI), and any other acute medical illness were excluded from the study.

Study participants were divided into three subgroups according to AAO, namely EOBD (AAO ≤21 years), IOBD (AAO = 22–34 years), and LOBD (AAO ≥35 years). There were 67, 59, and 36 patients in early, intermediate, and late-onset groups, respectively. The cutoff for AAO was determined on the basis of a review article by Geoffroy et al.[20] The cutoff value of 21 years for early onset was also recommended in other studies.[21],[22]

AAO was defined as “the age at which the patient first met criteria for a depressive episode, mania or hypomania as indicated by patient history, recall of family members and medical records.” This definition is close to the exact beginning of the illness and had been found to be highly reliable.[23]

After applying stringent inclusion and exclusion criteria, participants were subjected to the tools of study. Clinical interviews and symptom ratings according to the YMRS,[24] HAM-D,[25] and SAPS[26] were performed at the first presentation in the outpatient department.

These subgroups were compared with the following tools of the study:

Sociodemographic and clinical variables – A semi-structured pro forma was used to record the sociodemographic variables including age, sex, residence, occupation, marital status, monthly income, and education. Items occupation, education, and monthly income were adopted from the modified Kuppuswamy's socioeconomic scale.[27] This information was gathered from first-degree relatives and the patient himselfClinical assessment – The clinical variables were gathered through a clinical interview of participants and their immediate family members. The selection of clinical variables was based on literature review[28] and clinical observation. The clinical variables included number and duration of the illness (chronicity) and AAO of the illnessFamily history of mood disorder in first-degree relatives – Familial psychiatric illness was investigated using the Family Interview for Genetics Studies[29] applied by a trained psychiatrist. A complete family history of psychiatric illness of first-degree relatives was obtained from each proband and at least one first-degree relative. The information was supplemented by medical reports of relatives.Symptom-related variables – It was assessed using YMRS, HAM-D, and SAPS. Items were removed from the rating scales that were a priori considered redundant among them (i.e., similar symptoms rated more than once). Like, the HAM-D scale ratings of early, late, and middle insomnia; psychomotor agitation; and impaired insight were removed in favor of the YMRS ratings of items decreased sleep, disruptive or aggressive behavior, and impaired insight, respectively. The SAPS behavioral rating domain was removed in favor of YMRS ratings of disruptive or aggressive behavior and inappropriate appearance. The YMRS rating of content and language-thought disorder was removed in favor of the more comprehensive rating of delusion, hallucination, and thought disorder on the SAPS. Thus, a total of 24 symptom (9 from YMRS, 12 from HAM-D, and 3 from SAPS) ratings were analyzed.

Statistical analysis

Categorical/nominal variables were summarized as frequency and percentage and were analyzed using Chi-square test. Continuous variables were expressed as mean and standard deviation and were analyzed using one-way analysis of variance test or Kruskal–Wallis test as appropriate. The level of significance was set at $P < 0.05$. All analysis was performed using statistical software IBM SPSS Statistics for Windows, Version 19.0. (trial version) Armonk, NY: IBM Corp.

Results

A total of 162 patients were included in the final analysis. More than half (59.3%) of the patients were male. The three groups did not differ significantly regarding the gender distribution. Majority of the patients were from rural background (85.8%), married (74%), and belonged to lower socioeconomic status [Table 1].{Table 1}

There was a significant difference between the three subgroups regarding episodes per year; the early-onset group had significantly more episodes per year ($P < 0.001$) [Table 2]. The prevalence of family history of mood disorder was also significantly higher in the early-onset subgroup ($P < 0.001$) [Table 3].{Table 2}{Table 3}

Among these 35 affected families of early-onset probands, 51 first-degree relatives were found to be affected from mood disorder. Among these 51 first-degree relatives, 33 (64.7%) precipitated illness before the age of 21 years which indicates that they lay in the same early-onset group.

Manic, depressive, and psychotic symptoms revealed a significant difference in symptom profiles between the early, intermediate, and late-onset groups ($P < 0.001$). It was found that among different YMRS, HAM-D, and SAPS items, the EOBD group had significantly greater scores on irritability, motor activity–energy, sexual interest, depressed mood, delusions, and thought disorders than the other groups. Similarly, the LOBD group had a significantly greater score on elevated mood than the other groups [Table 4].{Table 4}

Discussion

BD patients were divided into three subgroups based on AAO (EOBD, IOBD, and LOBD), and a significant difference was found between the three subgroups on clinical presentation (different items of YMRS, HAM-D, and SAPS scale) and the presence of family history of the illness. Similarly, a previous study had divided BD patients into early-onset (age ≤20 years), intermediate-onset (age >20 to ≤30 years), and late-onset (age >30 years) subgroups. They found early-onset patients having more scores in hypersexuality, disinhibition, depressed mood, psychotic symptoms, and overall severity, whereas late-onset patients had greater scores on the Depression Rating Scale.[30] A study from Turkey also supported the hypothesis that adolescent-onset mania may be a different subtype than adult-onset mania with respect to type of episode, phenomenology, and clinical features.[31]

In the present study, depressed mood had a higher rating in the EOBD subgroup than the other groups, as was similarly reported by other studies from different countries.[30],[32] Another finding of the present study was that the psychotic symptoms, including delusions and thought disorder, were more common in the early-onset group, as was similarly reported by other researchers.[33] On the other hand, the LOBD group had a greater score on elevated mood. Supporting this, a study on geriatric population reported a greater average YMRS item rating for happiness and cheerfulness in elders with late onset compared to those with early-onset illness.[34]

In this study, early-onset patients experienced more number of episodes per year than the other groups, which indicates that they are more prone to be rapid cyclers. Supporting this, a previous study also reported that onset before 19 years of age eventually leads to the development of rapid cycling.[28]

Upon direct comparison of the EOBD and LOBD subgroups (the cutoff points were AAO before 18 years and after 40 years for the two subgroups), past literatures suggest that early-onset patients had more psychotic symptoms, mixed features, and family history of affective illness. EOBD and LOBD differ in clinical expression and familial risk and may therefore be considered to be different subtypes of manic-depressive illness.[33]

The family history of illness was significantly higher in the EOBD subgroup in the current study, and most of the first-degree relatives (64.7%) lied in the same proband (early onset) which supports the hypothesis that EOBD is a more heritable form of illness. Similarly, studies have found that bipolar siblings are much more likely to belong to the same theoretical AAO subgroup than to different subgroups.[11],[16] This finding confirms intrafamilial correlation for AAO in bipolar affective disorder. The existence of three “AAO subgroups” and the clustering of siblings in the same subgroup might be attributable to different genetic vulnerability factors supporting the view of genetic heterogeneity in BD.

Conclusion

AAO of BD is significantly associated with their clinical presentation and prevalence of family history of illness. The EOBD subgroup had significantly greater scores on several YMRS, HAM-D, and SAPS items, and greater prevalence of family history of illness can be considered as a specific phenotype of BD patients, which is more homogenous, severe, and heritable form of illness, could be a potential target for future genetic researches. AAO can be used a valid marker to identify homogenous subgroups in BD patients.

Limitations

Only patients of mania were included, and depressive patients were excluded for proper comparison of one aspect of illness. There is no standard definition of cutoff value of AAO, and the possibility of recall bias in reporting AAO could not be ruled out.

A Study on Assessment of Family Burden, Quality of Life and Mental Health in Caregivers of Patients with Schizophrenia

Sunil Kumar[1*], Paramjeet Singh[2], Raghav Shah[3], Ajitabh Soni[4]

[1]Senior Resident, Department of Psychiatry, Ananta Institute of Medical Sciences and Research Centre, Rajsamand. 2Senior Professor, Department of Psychiatry, SMS Medical College, Jaipur. 3Senior Resident, Department of Psychiatry, Post Graduate Institute, Chandigarh. [4]Assistant Professor, Department of Psychiatry, Govt Medical College, Churu.

ABSTRACT

Background: *Caregivers of patient with schizophrenia face a lot of burden which hampers their quality of life as well as mental health. This study was conducted to evaluate perceived burden of care, quality of life, and mental health in caregivers of schizophrenia patients and to explore the correlation between above parameters and total duration of illness of the patient with schizophrenia.* ***Methods****: The study was conducted at a tertiary care center. Participants were 99 caregivers of the patient with schizophrenia that were screened to ascertain whether they met the selection criteria. Perceived burden was scored by Family burden scale which is a semi structured interview schedule. Quality of life scale (WHO QoL-BREF Hindi version), was used to assess Quality of life. Modified Mini International Neuropsychiatric Interview was used to examine mental health of caregivers.* ***Results****: In the present study, total duration of schizophrenia showed statistically significant negative correlation with quality of life of caregiver. In the study, though the correlation between perceived family burden and total duration of schizophrenia was positive but it was not statistically significant. The burden also had statistically significant negative correlation with socioeconomic status and quality of life of the caregiver. The caregivers with high likelihood of mental illness scored significantly higher burden than other two groups.* ***Conclusions****: Caregivers of persons with schizophrenia do perceive burden, on account of which and along with lower socioeconomic status they experience poor quality of life and compromised mental health.*

Key words: *Burden of care, Schizophrenia, Quality of life, Duration of illness, Mental health.*

INTRODUCTION

Schizophrenia is a debilitating psychiatric disorder which not only influences the lives of those affected but also of their families. Schizophrenia is ranked among the top 25 leading causes of disability worldwide in 2013.[1] Of all the mental illnesses responsible for suffering in society, schizophrenia probably causes lengthier hospitalization, more chaos in family life, exorbitant costs to individuals and governments and fears than any other illness.[2]

In the past few decades, a shift towards community care and the deinstitutionalization of psychiatric patients has resulted in transferring of responsibility and day-to-day care of such patients to family members.[3] Families are thus assigned the role of primary caretakers for two reasons. First, there is a

Source of Support: Nil, **Conflict of Interest:** None

paucity of trained professionals required to execute psychosocial interventions and second, most Indian families would like to be meaningfully involved in all aspects of care of their ill relative.[4] Caregivers have to deal with patient's symptoms, and help patients in activities of daily living.

The caregiver is seen as the person who provides the most support to the patient, often devoting substantial number of hours each day towards taking care of the patient.[5] Caregivers spend a substantial amount of time interacting with their care recipients, while providing care in a wide range of activities. The patient's illness, behaviors, disabilities and perceived disruptions of the caregivers' lives are the stressors appraised by the caregivers.[6] The behavior of the patients with schizophrenia requires that the caregivers place their needs and wishes after those of their wards; consequently, the phenomenon has been labeled as a burden.[7-10] It refers to the presence of problems, difficulties or adverse events which affect the lives of caregivers.

There are stressful effects on the caregivers' own mental and physical health, like the feelings of stigmatization, inability to make or fulfill personal plans, empathic suffering for the pain of the ill member, worries for the ill member's future, especially if he/she is young. The behaviors of the patients and their management are issues that create ongoing tensions between the patients and their families.[11]

In India, care for other family members is an obligation and all caregivers perceive the burden. Providing care to a person with schizophrenia is often consistent and ongoing for long periods; and the role of the caregiver is stressful. The physical, mental and emotional toll of caregiving can be devastating and may lead to injury or illness of the caregiver.[12-16]

The stresses of caring for a relative with schizophrenia might lead to poorer quality of life and greater chances of physical and mental illness. Greater degree of depression and stress and low rating of subjective well-being in caregivers has been reported.[17-19]

The present study examines the caregiving burden and its correlates in primary caregivers of a patient with schizophrenia. This study aimed to evaluate perceived burden of care, quality of life, and mental health in caregivers of schizophrenia patients and to explore the correlation between above parameters and total duration of illness.

METHODS

A cross sectional observational study was carried out on caregivers of schizophrenia patient. Study was approved by research review board and ethical committee of the institution. The study included 99 caregivers of patients (The diagnosis was reviewed and confirmed by two psychiatrists independently based on ICD-10 criteria). An informed consent was obtained from the subjects prior to participation in the study. To include in study, the subjects were screened with a screening proforma that encompassed all the exclusion criteria. Those subjects who satisfied the screening process were recruited in the study. An informed consent was obtained from the patients and caregivers prior to participation in the study. This was followed by recording of socio-demographic profile and clinical profile. Each participant in the study was subjected to instruments of the study. This was followed by statistical analysis with the help of computer.

The study was conducted in the Department of Psychiatry, SMS Medical College, Jaipur which a tertiary care center. The study was conducted from 1st January 2012 to 31st December 2012. Family members of the patient attending the OPD or IPD were included in this study. They were screened by history to ascertain whether they met the selection criteria.

Inclusion criteria: Patients of either gender aged 18-60 years having diagnosis of schizophrenia as per ICD-10criteria, total duration of illness at least one year, who were living with a caregiver / family member for at least one year and provided informed consent; were included in the study.

Caregivers of either gender, aged 18-60 years, who were responsible for patient's care, living with the patient for at least one year and were spending more time with the patient than other family members, who were literate enough to read and understand the questionnaires and provided informed consent; were included in the study.

Exclusion criteria: Patients having a serious physical disability and Mental retardation were excluded. Caregivers with a physical disability (e.g. blind, deaf, speech problems), diagnosed psychiatric disorders, mental retardation and dementia, abusing substance other than nicotine, having color blindness; were excluded.

The subjects were interviewed after examination using the following instruments-

1. Consent form: This form was in Hindi language and was given before including the subject in study. The informed written consent was taken from each subject.

2. Socioeconomic status score was assessed using modified kuppuswamy scale for socioeconomic status.

3. Family Burden scale:[20] This is a semi structured interview schedule comprising of 24 items grouped under these areas: financial burden, disruption of routine family activities, disruption of family leisures, and disruption of family interaction, effect on physical health of others and effect on mental health of others. The burden is rated on a 3- point scale for each item, and a standard question to assess the subjective burden is also included. This scale has been developed for the Indian set up, keeping in the mind the socioeconomic and cultural conditions in the India. The validity and reliability of the scale have been found to be satisfactory. The interrelated reliability for each item was reported to be more than 0.78 by the authors, which indicates that the present schedule is a reliable tool.

4. Quality of life scale (WHO QoL-BREF version): .[21] An abbreviated version (WHOQOL-Bref, Hindi) of 26 items is developed using data from the field-trial version of the WHOQOL- 100. The WHOQOL-Bref contains two items from the overall QOL and general health, and one item from each of the remaining 24 facets included in the WHOQOL-l00. This scale provides a profile of scores on four dimensions

of quality of life: physical health, psychological, social relationship, and environment. Its 26-items look at domain level profiles and are self-administered. Higher scores mean higher quality of life.

5. Modified mini International Neuropsychiatric Interview (MINI) (22): It is a 22 item questionnaire that is administered by a clinician in about 15 minutes. The tool uses a set of gateway questions that relate to signs of distress that may be attributable to a diagnosable psychiatric disorder. The screen is divided into 3 sections to capture the three major categories of mental illness as follows: Section A- Mood Disorders, Section B-Anxiety Disorders, and Section C- Psychotic Disorders. Scoring of the Modified Mini Screen is straightforward and additive. A "YES" response to a question on the screen converts to 1 point. The clinician adds all the positive (yes) responses for a total score, which ranges from 1 to 22 points. There are three different cut points and each cut point determines a different plan of action for the client.

CUTPOINT 1 is score ≤ 5. No further action is needed. This plan of action is based only on the screen, but a screening tool should never replace clinical judgment and critical observations by staff.

CUTPOINT 2 is between 6 and 9. The treatment team determines whether there is a need for a mental health assessment. If it is determined that a mental health assessment is not required, enhanced ongoing monitoring for mental health needs will be implemented as part of the initial comprehensive treatment plan. If it is determined that a mental health assessment is needed, action proceeds as listed below for CUTPOINT 3.

CUTPOINT 3 is any one of the following: - Adults who scored ≥ 10 or adults who answered "yes" to question 4or Adults who answered "yes" to both questions 14 and 15. For cut point 3, the client will receive a mental health assessment, which means an evaluation to determine whether a client has unmet mental health needs and includes recommendations for treatment or further evaluation if indicated. Question 4 relates to suicidality. Any client who answers YES to this question should be referred for a mental health assessment regardless of the total score. Questions 14 and 15 refer to Post Traumatic Stress Disorder (PTSD). PTSD does not only address combat/war, but also addresses experiences of physical and sexual abuse, as well as other trauma. If both questions 14 and 15 are answered YES, the client should be referred for a mental health assessment regardless of the client's total score.

Data analysis

Statistical analysis was done with the help of computer. Quantitative data was expressed as frequencies and quantitative data as mean and standard deviation. Group comparisons for quantitative data were done with the help of non-parametric test i.e. Independent-Samples Kruskal-Wallis Test as the data did not have normal distribution and homogeneity of variance. Further group differences were obtained with the help of post-hoc analysis (group-wise comparisons). Correlations were computed by Pearson's correlation analysis.

RESULTS

The sample in present study comprised of 99 subjects. Table 1 shows socio-demographic and clinical variables of patients and caregivers and mean scoring on the three scales.

Table 1: Socio-demographic, clinical variables of patients and caregivers and scoring on the three tools:

S. No.	Variable	Details
1.	Patient's age	22 to 65 years (Mean =39.68, SD=12.06)
2.	Patients gender	Male = 69 Female = 30
3.	Patients marital status:	Married = 90 Unmarried = 9
4.	Total duration of illness of patient	1-30 years (Mean= 10.08, SD= 7.06)
5.	Caregiver's age	18-56 years (Mean=32.66, SD=11.81)
6.	Caregiver's gender	Male = 86 Female = 13
7.	Mean family burden total score of the sample	36.35 (SD=10.67)
8.	Mean Quality of life total score of the sample	70.48 (SD=15.58)
9.	The number of caregivers in Modified MINI cut-points	Cutpoint 1: 29 (29.3%) Cutpoint 2: 24 (24.2%) Cutpoint 3: 46 (46.5%)

SD=Standard deviation

Table 2 shows that of total duration of illness is inversely correlated with the quality of life score, and is directly correlated with the family burden score.

Table 2: Correlations of total duration of illness with family burden and Quality of life

		FBS Score	QoL score
TDI	Pearson Correlation	0.025	-0.246
	Sig. (2-tailed)	0.808	**0.014**

TDI= total duration of illness, **FBS**= Family burden scale, **QoL**= Quality of life

Table 3 shows family burden total score is negatively correlated with both socioeconomic status score and quality of life total score.

Table 3: Correlations of family burden with socioeconomic status and quality of life

		SES Total score	Total QoL Score
FBS	Pearson's Correlation	-0.210	-0.477

MINI Cutpoint 2 (24)	35.17(10.7)	20.6	2	**0.00**
MINI Cutpoint 3 (46)	41.24(7.5)			

N= number, SD= Standard deviation, df= degree of freedom

Table 4 (b): Post hoc analysis

Sample	Test statistic	Std. error	Std.test statistic	Sig.	Adj.sig
MINI Cutpoint 1-2	-12.7	7.9	-1.6	0.10	0.323
MINI Cutpoint 1-3	-30.3	6.8	-4.4	0.00	**0.000**
MINI Cutpoint 3-2	-17.5	7.2	-2.4	0.015	**0.045**

DISCUSSION

In the present study, total duration of schizophrenia showed statistically significant negative correlation with quality of life of caregiver. In the study, though the correlation between perceived family burden and total duration of schizophrenia was positive but it was not having statistical significance. The burden also had statistically significant negative correlation with socioeconomic status and quality of life of the caregiver. The caregivers with high likelihood of mental illness scored significantly higher burden than other two groups.

The duration of caregiving did not vary significantly with the total burden score in the study, which emphasizes that longer (after one year) periods of caregiving did not necessarily result in greater caregiver's burden. The trend is that prolonged caregiving does not result in increased burden or psychological distress. It is seen that with increasing duration of patient's illness, the family tends to adjust its ways and means according to patient's illness and hence, burden felt is not as much as expected. This finding is consistent with other studies.[1] also found that the duration of illness of the patients did not correlate with the carers' burden or needs. McDonell et al.[26] also reported that duration of the illness was not a significant independent predictor of burden. Contrary to our findings, total burden was found to be significantly more if duration of illness was more.[27] Leyla et al.[28] also observed that the burden of care was positively correlated with the total duration of illness.

Total duration of illness had significant negative correlation with quality of life score. ZamZam et al.[29] also reported that less duration of illness was significantly associated with higher scores in all domains of the caregivers' Quality of life. So it is suggested that the threatening nature of positive symptoms and more negative symptoms of schizophrenia make the patient more intolerable to caregivers as the illness becomes more chronic. Sales.[30] also reported that caregivers have poor quality of life as they are burdened and strained for long duration. The chronic burden of everyday living profoundly reduces the quality of life and declines satisfaction.

In the present study, family burden score had negatively significant correlation with both socioeconomic status and quality of life scores. Besides providing care for ill member, caregivers also have to solve financial problems and find out sources of money. Family burden in caregivers of patients is a disability related to work, participation in household duties and lack of self-care, satisfaction with mental health services, and social relationships, nuisances, and burden due to restricted social life and leisure activities, worries about the patients' health, future, and safety. Other studies.[31,32] also found supporting results. Two studies.[33,34] also showed that low income was associated with a higher degree of burden on the caregivers. Lower income is a stressor that influences perception of caregiver's burden while providing care for the ill family member.

As per modified MINI groups (according to Cutpoint 1-3), these groups differed significantly in the mean of burden score and it was found that more caregivers fall in high likelihood of mental illness group (cutpoint-3) and this group scored significantly higher burden than other two groups. Aydın et al 2009 also reported that as the burden of care increased, the level of anxiety and depression in caregivers also increased. Similar to our study, Noh and Turner.[35] also reported that burden was a major source of stress. Lowyck et al.[36] also concluded that key relatives taking care of the patient do experience an ample amount of burden, on both a practical and emotional level; and the number of the symptoms exhibited by the patient was an influence on family burden.

CONCLUSION

In this study, the authors found that the duration of schizophrenia does not significantly influence the level of burden but it does significantly affect the quality of life. The caregivers of lower socioeconomic status perceived higher family burden and have poor quality of life. The caregivers with higher family burden also showed significantly higher likelihood of developing mental illness. Though it was a cross-sectional study with small sample size, but it can be a directive for future case control studies that may be done on longitudinal basis with large sample sizes to allow generalization of the significant findings and promote holistic management of families harboring person with chronic mental illness.

Abstract

Background: Drug abuse affects the health and lives of millions of individuals across the world. Discrimination faced by substance users and stigmatization becomes a barrier for them thus these patients do not receive the required care and treatment they deserve. The negative perception of healthcare professionals leads to poor therapeutic alliance between them and the patients of substance use. Current study aims to determine and assess the attitudes of the health professionals towards patients with substance use problems and to identify factors causing diverse attitudes of health professionals towards these patients.

Method:A questionnaire based cross sectional study was undertaken at Ananta hospital Rajsamand (a tertiary health care centre) which included 134 health professionals both doctor and nursing staff for a duration of one year who provided their consent for this project. The socio- demographic details of every participant was collected and all of them were given the DDPPQ tool which assessed their attitudes and perception towards drug and drug use problems.

Results: Younger age group of health professionals showed better outlook towards patients of drug abuse. A linear regression of gender, professional roles (i.e. doctors and nurses), past history of substance abuse and known history of substance abuser in the family with the principal component does not yield any significant results. Majority of the participants had either neutral opinion or positive opinion towards the problem of drug use and the drug users.

Conclusions: Healthcare professionals with age on the lower side had more positive regards and significantly positive attitudes towards the problems of substance use and therefore the

therapeutic compliance was better. Healthcare delivery needs unbiased and non-judgmental attitude of healthcare professionals towards patients of substance abuse, so in an attempt to provide holistic approach and care that overlooks socio-demographic and clinical profiles, professionals should have adequate and appropriate training and exposure accordingly.

Keywords: Professionals, nursing, staff, substance, drug, perception, attitudes, stigmatization.

Introduction

Drug abuse is a global phenomenon which affects almost every country with a variable extent. Abuse of illicit drug affects the health and lives of many individuals across the globe. The criminalization of this addictive behavior damages the reputation of the engaged person and it also deters other people, leading to stigmatization of the problem in the society. Stigmatization also discourages illicit drug users from getting health care due to fear of poor treatment by health care providers or fear of trouble with the authorities[1,2]. While stigma and discrimination may serve as deterrents to illicit drug use, these attitudes also contribute to discrimination and stigmatization experienced by illicit drug users which may be bad for drug user's health[3]. Negative attitudes of health professionals towards patients with an alcohol or other drug addiction are known to lead to poor communication between professional and patient, diminished therapeutic alliance, and mis-attribution of physical illness symptoms to substance use problems, also referred to as diagnostic overshadowing[4,5].

In this scenario, medical professionals are key persons in the provision of care for persons who exhibit problems related to use of the substances of abuse. Personal factors[6] and deficient medical education about addiction in health professionals[7] influence the under-diagnosis of substance abuse disorders. Studies have found that physicians were significantly less satisfied when caring for patients with drug problems compared to other illnesses[8]. A study on nurses found that nurses struggled with the care for patients who use illicit drugs and they had less motivation, satisfaction, role support and education[9]. Another study found that staff who had received training held fewer negative attitudes towards illicit substance users regardless of their length of clinical work experience or type of work setting[10]. Another study found that health professionals' regard was lowest for patients with drug and alcohol problems, lowest regard was found among physicians who did not work in specialized addiction services[11]. This study found that specially trained personnel's in this field such as psychologists, social workers, and professionals in the addiction services showed the highest regard while physicians who did not work in specialized addiction services had lowest regard. People with drug related disorders deserve the same level of care as patient with any other health condition. Health service need to be able to identify drug use and drug use disorder at an early stage and provide prevention, treatment and harm reduction intervention. We could not find any study in our region addressing health professional attitudes towards persons with problems related to substance use.

Aims and Objectives

Current study aims to assess and determine the attitudes of the health professionals

towards patients with substance use problems and to identify factors causing diverse attitudes of health professionals towards these patients.

Methods

Study area

The study was conducted at Ananta Hospital Rajsamand (attached to Ananta Institute of Medical Science and Research Centre, Rajsamand, Rajasthan) a tertiary care hospital.

Study Design

Questionnaire based cross sectional study

Study Participants

Health Professionals (Including doctors and nursing staff)

Study duration

One Year, September 2019 to August 2020.

Sample size

A total population of health care professional of 200 working in Ananta Institute of Medical Science and Research Centre, Rajsamand, Rajasthan, a tertiary care hospital. Minimum of 134 participants were expected to participate according to the following calculation.

$N^* = N*X / (X + N - 1)$,

where,

$$X = Z^2_{1-\alpha}\, p(1-P)/d^2$$

where alpha (α) = 0.05, estimated proportion (p) = 0.50, estimated error (d) = 0.05 and N is the population size

The Finite Population Correction is used to adjust a variance estimate when sampling without replacement.[15]

A stratified random sampling technique has been used for collection of data. A validated 22-item DDPPQ questionnaire tool has been used in the study.

Statistical analysis

Questionnaire data was analyzed using SPSS version 24. Socio demographic data were summarized using frequencies and percentages. Means and standard deviation were used for continuous variables. Mann Whitney U test was used to compare the difference among professional groups i.e. doctors and nurses. The relationship between DDPPQ scores and other relevant variables was analyzed by using Pearson Product-Moment Correlation Co-efficient. The regression analysis has been done to find out relationship between independent and dependent variables. Statistical significance was taken at the 5% level.

Data Collection Procedure

The 22-item validated version of Drug and Drug problems perception questionnaire (DDPPQ) instrument was used for the study[12]. The validated DDPPQ, comprises of 22 items and is a shorter questionnaire, having retained only the most reliable items from the original instrument. The items of the validated questionnaire are numbered consecutively from one to twenty-two. The validated DDPPQ is a self-complete 'paper and pencil' questionnaire. Respondents are asked to rate their level of agreement on a series of 22 statements about working with people who use licit or illicit drugs in a nontherapeutic way. There are seven possible responses to each item on a scale of Strongly agree' to 'Strongly disagree'. Low scores denote positive attitudes, whereas high scores are associated with negative views. Several of the items are worded negatively. These are Items 15, 16, 17 and 18. For the purpose of this study, the DDPPQ were expressed on a 5-point Likert scale ranging from 1 = strongly agree, 2 = agree, 3 =neither agree nor disagree, 4 = disagree to 5= strongly disagree

.A 5 - point Likert-type scale instead of 7-point was used to increase response rate and response quality along with reducing respondents' frustration level[13]. Factor structure of the validated DDPPQ has yielded its six factors which are role adequacy, motivation, role legitimacy, task specific self-esteem, role support and work satisfaction

Study Variables

The independent variables in the study are the socio-demographic characteristics of the study participants such as gender, age, profession, work motivation and role support of health professional. The dependent variables, attitude and perception are measured by six factors/ subscale measure (using 5- point Likert scale) in the DDPPQ. Questionnaire data was analyzed using SPSS version 24. Socio-demographic data were summarized using frequencies and percentages. Data was analyzed by using unrelated T-test, Mann Whitney U test and Pearson product moment correlation coefficient.

For the questionnaire survey, 22 items of validated version of DDPPQ questionnaire was distributed individually to the 152 professional group members in a sealed envelope and returned back in same sealed condition in order to maintain privacy of participants. One hundred and thirty-four participants returned the completely filled up questionnaire. All professional group members i.e. both doctors and nursing staff members responses to the given DDPPQ questionnaire were calculated to give a total attitude score. The minimum score for the DDPPQ is 22 and the maximum score is 110. The higher the score obtained indicates an increasingly more negative attitude.

Results

Table 1: gives description of number of participants according to the gender as well their professional roles.

Group	Number (Total=134)	Percentage
Doctors	85	63.4 %
Males	53	39.5 %
Females	32	23.8 %
Nursing staff	49	36.5 %
Males	30	22.3 %
Females	19	14.1 %

Table 1. Profile of the Sample

Table 2: shows profile of the sample according to professional group and gender.

	Number of responses	Score Range	Mean Score (SD)	Z score	P* Value
Doctors	85	24-76	49.63 (8.95)	-0.30	0.75
Nursing Staff	49	33-68	49.46 (9.52)		

Table 2. The DDPPQ Score Range for Professional Groups

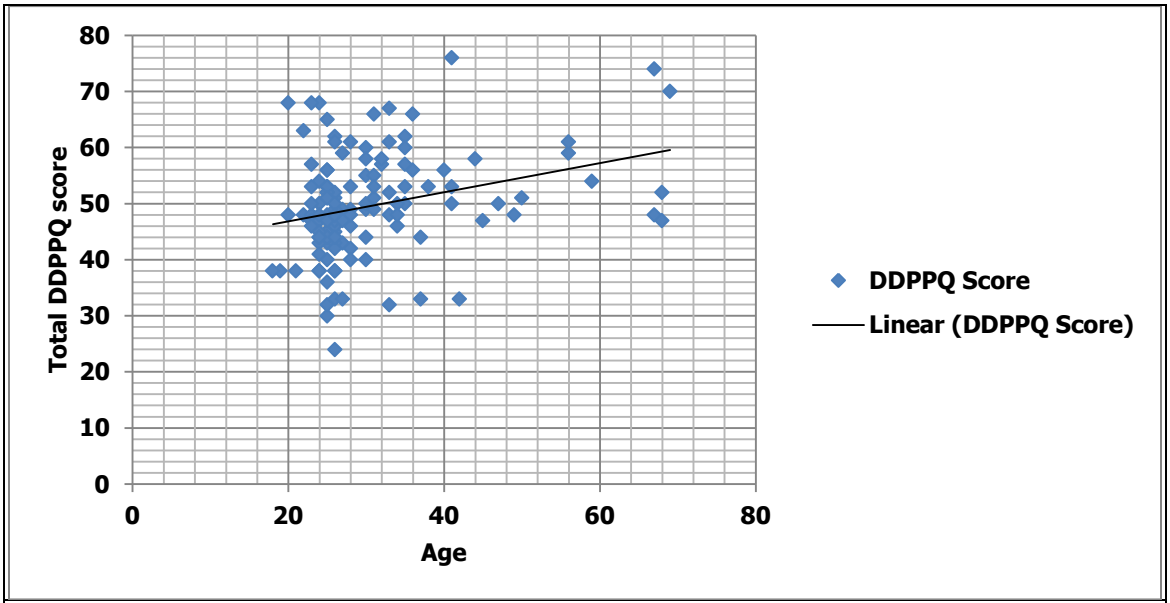
Mann Whitney U test. * The result is significant at $p<0.05$

Table 2 shows the DDPPQ score range for the participants. A Mann-Whitney U test was conducted to compare DDPPQ scores between doctor and nursing staff. The result is not significant at $p<0.05$. There is no difference between the groups.

Age of Participants Versus DDPPQ Score

Mean age of the total sample was 30.56 years (standard deviation 10.38). Mean age for doctors' group was 32.85 years (standard deviation= 11.86) and for nursing staff group was 26.59 years (standard deviation=5.21).

There is significant correlation between the age of the professional group members i.e., both doctors and nursing staff members and their respective DDPPQ scores when calculated using Pearson Product – Moment Correlation Co-efficient (2 tailed) $r = 0.29$, $n = 134$, $p = 0.00067$.



Graph 1: Distribution Graph of Age Versus Total DDPPQ Score

The graph indicates weak positive correlation between age of the participants and their corresponding DDPPQ score.

Family History versus DDPPQ Score

Participants were also asked if they had any family history of substance abuse and past history of substance abuse.

Table 3: Comparisons among Health Professional having Family History of Substance Abuse and Past History of Substance Abuse

	Response	Number of Responses	Range	Mean (Standard Deviation)	Z Score	p*Value
Family history of substance abuse	Positive	22	43-63	52.09(5.97)	-1.786	0.074
	Negative	112	24-76	49.08(9.57)		
Past history of substance abuse	Positive	23	38-65	50.17(7.16)	-0.393	0.694
	Negative	111	24-76	49.45 (9.51)		

Mann Whitney U test. * The result is significant at $p<0.05$

In Table 3, comparisons among Health professional having family history of substance abuse and past history of substance abuse are described. Using Mann- Whitney U test, we found that there is no statistical difference between the groups of health professional having past history of substance abuse and health professional who don't have past history of substance and the groups of health professional having family history of substance abuse and health professional who don't have family history of substance abuse.

A linear regression of gender, professional roles (i.e., doctors and nurses), past history of substance abuse and known history of substance abuser in the family with the principal component has not yielded any significant results.

Table 4: Health Professional Therapeutic Commitments towards Drug Abusing Patients on various Subscales of DDPPQ and total Mean Score

Subscales	Number of Questions	Mean Score Per Question (LikertScore = 1-5)	Standard Deviation
Role adequacy	8	1.99	0.65
Role Legitimacy	3	1.85	0.71
Role support	3	1.92	0.64
Work satisfaction	4	2.18	0.76
Motivation	1	3.58	1.17
Task specific Self Esteem	3	3.39	1.07
Total Score	22	49.57 (possible score 22-110)	9.13
Note: lower score denotes higher therapeutic commitment.			

Table – 4 shows a mean of total score of 49.57 (SD = 9.13) with a possible score between 22 and 110. **The diverse attitudes of Health Professionals towards substance abusers**

Table 5: Percentage of Participants in three Categories

	Frequency	Percentage
Positive [a]	36	26.86
Neutral [b]	91	67.92
Negative [c]	7	5.22
	134	100
a= Total score from 22 to 44; b) total score from 45 to 66; c) total score from 67 to 110		

The total DDPPQ scores were divided into three categories i.e. (1) Positive perception (distinctly defined perception of role), (2) Negative perception (lack of distinctly defined perception of role) and (3) neutral perception (neither distinctly defined perception of role nor lack of distinctly defined perception of role). The range for all three perceptions was determined by the possibility maximum and minimum score in 5 point- Likert scale. Table 5 shows percentage of participants in these three categories.

Discussion

Current study aimed to assess and determine the attitudes of health professionals towards patients with substance use problems in our region and to identify factors causing diverse attitudes of health professionals towards these patients. There was weak positive correlation between age of the participants and their

corresponding DDPPQ score that is older health professionals had relatively negative attitude. This was in contrast to a study that found that older nurses believed more strongly that alcoholism is an illness[14]. The two professionals' groups were assessed by comparing health professionals having family history of substance abuse and past history of substance abuse, and it was found that there is no statistical difference between the two groups of health professional. The mean DDPPQ score in these groups ranged towards lower side denoting positive attitude towards these patients, means their past or family history of substance use didn't significantly affect the attitude. Our study found that there was no statistically significant difference between the DDPPQ scores between the two groups i.e., doctors and nursing staff.

Considering all participants in a group, the lower skewed total mean DDPPQ score of 49.57 (SD = 9.13, with a possible score between 22 and 110) in our study correlated with a more positive attitude and higher therapeutic commitment to drug abusing patients. On mean Likert-format response per question (of 1= Strongly agree to 5= Strongly disagree), the highest therapeutic commitment is reflected in role legitimacy subscale which indicated the degree that professional group members felt that drug abuse history taking and counseling was a professional responsibility. Role support and Role adequacy followed the next which reflected that professional group members felt that they have adequate knowledge of drug and drug related challenges. Also whenever required, they will get support or help to resolve drug related problem. Highly skewed score in motivation and self-esteem subscale reflected lower therapeutic commitment. Role support, role adequacy, role legitimacy and work satisfaction were all somehow interconnected with each other at the basic level along with motivation and self-esteem to aid in understanding of the plight of patients of substance abuse and thereby providing therapeutic care and overall management to such patients. Our findings are in contrast to another study which found that healthcare providers struggled with the care for patients who used illicit drugs and they had less motivation, satisfaction, role support and education.[9]Crothers and Dorrian also found high scores regarding work satisfaction which indicated that nurses' attitudes regarding how much they like, and feel rewarded by, working with patients with alcohol problems, are an important determinant of the extent to which nurses are actually willing to engage in this work[15].

In an attempt to identify diverse attitudes of health professionals towards substance abusers, the sample participants were divided into three categories for ease of understanding - Positive perception, Negative perception and neutral perception; and it was found that number of healthcare professionals having neutral perception were maximum, followed by those having positive perception and least holding negative approach to the drug abuse patients. In a study nurses appeared to have, on average, attitudes that were consistently quite positive, if not neutral[14]. As healthcare professionals are the chief gatekeepers in the management of patients who suffer from substance use disorder, there is need of the hour to change both the neutral and negative attitude of the health care workers into positive attitude. To improve local services, Howard et al recommended that a training strategy should be developed with consideration to a structured programme covering all aspects of providing care to inpatients with co-occurring mental health and substance use problems; implementing training and support structures for staff will enable them to deliver more recovery and client centered interventions for patients with these co-occurring issues[10].

Healthcare delivery needs unbiased and non-judgmental attitude of healthcare professionals towards patients of substance abuse, so in an attempt to provide holistic approach and care that overlooks socio-demographic and clinical profiles, professionals should have adequate and appropriate training and exposure accordingly. We propose some ways that can be executed systematically to bring about the necessary change in the attitudes of a healthcare professional- First and foremost is sensitization of healthcare professionals (both the doctors as well as the nursing staff) which is primarily important to achieve better outcomes in management of patients of substance use disorders. Secondly, there are ways to be incorporated at the grass root level which directly and/or indirectly will have an impact on the management of such patients include: (i) training – providing education and skills to the professionals and conducting workshops at regular intervals, teaching institute – both the medical colleges and the nursing colleges are jointly responsible in training the students who take up this field and providing opportunities for them to learn,(ii) exposure – mandatory rotatory postings for every undergraduate medical/nursing student to understand patients from having them visit an addiction wing facility of outdoor and indoor patients run by the department of psychiatry at the institute where they come across such patients of substance abuse.

Conclusion

Our study found that the younger age group healthcare professionals had more positive outlook and attitude towards substance users. The lower skewed total mean score of participants denoted more positive attitude and higher therapeutic commitment. Subdivision of the participants in three groups to a step forward revealed that majority of them had either positive or neutral attitude towards patients with problem of substance abuse, leaving a minority or handful percentage of participants who had negative perception and attitude.

Implications of the Study

our study will help in identifying diverse attitude of health professional towards patients with substance use disorders and the associated factors. Awareness and proper education along with skills instilled among these healthcare professionals will strengthen the belief and trust of the patient receiving treatment and management during the prolonged period provided for deaddiction. The provision of adequate, timely guidance and motivation at every step to reduce the use of illicit substances, would help in controlling the menace of drug abuse can be well achieved.

Limitations

This was a cross sectional study with small sample size.

Future Direction

Future studies can be undertaken with large sample size to determine the changes in attitudes and knowledge of healthcare professionals prior to any kind of exposure or training received and followed up by assessing them after they have achieved skills, knowledge and training in the field of addiction psychiatry.

Impact of Cognition and Clinical Factors on Functional Outcome in Patients with Bipolar Disorder

A Soni, P Singh, R Shah, S Bagotia

Abstract

Objective: To examine the role of different clinical variables and cognition on functional outcome in patients with bipolar disorder.
Methods: A total of 61 euthymic patients with bipolar disorder and 30 healthy individuals were included in the study. The patients were divided into low functioning (n = 30) or high functioning (n = 31) subgroups based on functioning level measured by Global Assessment of Functioning Scale score. Groups were subjected to neurocognitive and clinical assessment.
Results: Clinical variables differed significantly between low and high functioning patient groups, namely total number of episodes, depressive episodes, and time since the last episode. These variables were also correlated significantly with Global Assessment of Functioning Scale score. All 3 groups differed significantly for digit span backward test, verbal learning and memory test, Trail Making Test, and Stroop Colour Test. Digit span backward test, Trail Making Test, and Stroop Colour Test were significantly correlated with Global Assessment of Functioning Scale score.
Conclusions: Total episodes, depressive episodes, time since the last episode, and cognitive dysfunction correlated with poor functioning. Executive dysfunction was the strongest predictor of psychosocial outcome in euthymic bipolar patients. Long-term therapeutic interventions should target relapse prevention with special consideration given to depressive episodes and cognitive rehabilitation.

Key words: *Bipolar disorder; Cognition; Depressive disorder*

Introduction

Bipolar disorder has traditionally been associated with a better outcome than schizophrenia.[1] Nonetheless generally little attention has been paid to psychosocial outcomes in patients with bipolar disorder. Recent studies indicate that functioning varies considerably as far as the outcome is concerned: some patients function well in between episodes whereas others have substantial dysfunction in significant functional domains, even during euthymic periods.[2-4]

Several clinical variables are associated with poor functioning in patients with bipolar disorders including number of episodes,[5] persistent subsyndromal symptoms,[6] prior number of psychiatric hospitalisations,[7] co-morbid substance use disorder,[8,9] side-effects of medicine, history of psychotic symptoms,[4,10] early age at onset,[4,11] longer duration of mood episodes,[12] and low premorbid functioning.[13] Growing evidence suggests that bipolar disorder patients experience prominent neurocognitive impairment not only during acute mood episodes[14,15] but also during euthymia.[16,17] The cognitive deficits intrinsic to bipolar disorder itself typically coalesce around problems with attentional processing, executive function, and verbal memory.[18,19]

Functional outcome in bipolar disorder is significantly influenced by clinical variables related to the illness and cognitive functioning. The current study aimed to assess the relationship of these factors to functional outcomes in bipolar disorder.

Methods

This was a cross-sectional hospital-based analytical observational study carried out between 16 February 2014 and 28 December 2014 on euthymic bipolar patients who attended the outpatient department of the psychiatric centre, SMS Medical College Jaipur, India. Ethical approval was obtained from the research review board and ethical

committee of the institution. Informed written consent was obtained from all participants prior to participation in the study.

A total of 61 patients were included over a period of 1 year. Male and female patients with bipolar disorder (according to the ICD-10 research criteria and confirmed by clinical interview of the participants and their immediate family members) aged 18 to 55 years who were currently euthymic (defined as Young Mania Rating Scale[20] score of ≤ 6 and 17-item Hamilton Rating Scale for Depression[21] score of ≤ 8) were recruited. Participants were required to have at least 7 years of formal education to reduce the confounding effect of education on cognitive tests.

Patients with a history of head injury, neurological illness, any other co-morbid psychiatric illness or substance abuse in the last year except nicotine abuse (assessed by the Mini-International Neuropsychiatric Interview [MINI]),[22] mental retardation or any clinical condition that could affect cognitive performance, significant medical illness, electroconvulsive therapy in the last year, or physical disability (e.g. blind, deaf, speech problems, paralysis, amputation) were excluded.

Thirty healthy individuals, carefully matched with participating patients for age, gender, locality and education, were recruited from "bystanders" of the patients (e.g. spouse, distant relative, or the person accompanying the patient) to reduce the effect of confounding variables. Those who had a history of psychiatric illness (by MINI[22]) or a history of psychiatric illness in a first-degree relative (confirmed by clinical interview) were excluded from the study.

The patients were divided into low functioning (n = 30) and high functioning (n = 31) subgroups based on functioning level as measured by Global Assessment of Functioning Scale (GAF) score.[23] The GAF[23] assesses psychological, social, and occupational functioning with a possible score of 1 to 100. A score of 60 was set as the cut-off to distinguish patients with high and low functioning. As per the DSM-IV-TR, a score of > 60 (61-70) indicates some mild difficulty in social, occupational or academic activities or satisfactory activity. Nonetheless in general, the patient works quite well and has significant interpersonal relationships. A score of ≤ 60 indicates moderate to severe impairment in functioning. This cut-off has been recommended by earlier studies to distinguish poor functioning patients with psychiatric disorders.[12,24] We used the GAF score to measure psychosocial functioning in the month prior to rating. After applying inclusion and exclusion criteria, 3 groups were assessed.

Socio-demographic profile included name, age, gender, name of father / husband, address, marital status, education, occupation, type of family, and monthly income. Clinical variables were recorded following clinical interview of participants and their immediate family members. Number and type of episodes, duration of illness (chronicity), age at onset of the illness, number of hospitalisations, time since the last episode, and history of psychotic symptoms were recorded. The investigator was blinded to the group category.

Neuropsychological assessments used in this study included the digit span forward test[25] and the Trail Making Test part A[26] for testing attention and concentration; Trail Making Test part B,[26] the digit span backward test[25] and the Stroop Colour Test[27] for executive function; and verbal learning and memory test in Hindi.[28]

Assessment was performed in a fixed order in a quiet room by a trained psychiatrist who was blinded to the group category and took 45 minutes to 1 hour to complete.

Statistical Analysis

Data were analysed using the Statistical Package for the Social Sciences (SPSS Windows version 19.0; IBM Corp, Armonk [NY], United States). Socio-demographic variables of the 3 groups (high functioning, low functioning, and healthy controls) were compared using analysis of variance and Chi-square test as appropriate. Clinical variables of the 2 patient groups (low and high functioning) were compared using independent-samples *t* test and Chi-square test as appropriate. Multivariate analysis of variance (MANOVA) was performed to assess the difference in neurocognitive test results between the 3 groups followed by Tukey's post-hoc analysis that was significant on MANOVA analysis. Descriptive statistics were expressed as mean and frequency as appropriate. Pearson's correlation was applied to determine correlation among variables. Variables significantly correlated with GAF score were introduced into the linear regression analysis to identify better predictors of functional outcome. A p value < 0.05 was considered significant.

Results

The socio-demographic profiles of the 3 groups were comparable. Most patients were married (78%), Hindu (89%), and male (60%) with a rural background (75%) and belonged to an upper lower or lower middle class family (91%). Most patients (54%) lived in a nuclear family. The mean durations of education were 8.6, 8.5 and 8.9 respectively in low functioning, high functioning, and control groups (Tables 1 and 2).

Table 3 shows the comparison of clinical variables between low and high functioning groups. A significant difference was evident in the total number of episodes (p = 0.003), depressive episodes (p = 0.001), and time since the last episode (p = 0.000).

Table 4 shows the correlation of different clinical variables with GAF score. In Pearson's correlation analysis, total number of episodes (r = –0.459, p = 0.000), number of manic episodes (r = –0.299, p = 0.02), depressive episodes (r = –0.481, p = 0.000), and time since the last episode (r = 0.698, p = 0.000) were significantly correlated with GAF score.

With regard to neurocognitive variables, MANOVA yielded Pillai's F of 4.976 (p = 0.000) for the main

Table 1. Socio-demographic characteristics of the sample.*

	Groups			X^2 value	p Value
	Low functioning (n = 30)	High functioning (n = 31)	Healthy controls (n = 30)		
Marital status				1.520	0.82
Married	22 (73)	24 (77)	25 (83)

Table 2. Comparison of age and years of education among groups with analysis of variance.

	Mean ± standard deviation			p Value
	Low functioning group	High functioning group	Healthy controls	
Age (years)	32.9 ± 10.4	34.4 ± 7.6	31.7 ± 8.4	0.49
Years of education	8.6 ± 1.3	8.5 ± 1.1	8.9 ± 1.5	0.47

effect, indicating an overall difference in neurocognitive performance between groups. As shown in Table 5, multivariate analysis revealed that the 3 groups differed significantly for digit span backward test ($p = 0.01$), verbal learning and memory test ($p = 0.001$), Trail Making Test part A and B ($p = 0.000$), and all the 3 Stroop Colour Tests ($p = 0.000$). Multiple comparisons by Tukey's post-hoc analysis were made to determine which 2 groups differed significantly in head-to-head comparison. Table 6 shows the mean difference and p value for each comparison. Digit span backward test, Trail Making Test (part A and B), and Stroop Colour Test were significantly correlated with GAF score (Table 7).

In an attempt to find the predictors of psychosocial functioning, those variables that correlated with psychosocial outcome ($p < 0.05$) were introduced in the linear regression analysis. Variables significantly correlated with GAF score were total number of episodes, number of manic episodes, number of depressive episodes, time since the last episode, digit span backward test, Trail Making Test (part A and B), and Stroop Colour Test. This model accounted for the 65.5% variance in psychosocial functioning ($F = 15.22$, $t = 5.26$, $p = 0.000$). The better predictors of psychosocial functioning among all the variables were time since the last episode ($ß = 0.475$, $p = 0.000$) and interference Stroop Colour Test ($ß = –0.290$, $t = 2.82$, $p = 0.01$).

Discussion

The present study was designed to assess the impact of clinical and cognitive factors on functional outcome in euthymic patients with bipolar disorder. Patients were divided into low and high functioning groups based on GAF score (cut-off, 60) and several clinical factors compared. Those selected in this study were based on earlier studies.[5,6,11,12] Neurocognitive performance was assessed by comparing the low and high functioning groups with the controls for digit span test, Trail Making Test, Stroop Colour Test, and verbal learning and memory test. Further analysis of the relationship of GAF score with clinical and cognitive factors was performed to identify better predictors of functional outcome in bipolar disorder. All 3 groups were comparable for age, gender, locality, education, and other socio-demographic variables.

Impact of Clinical Factors on Functional Outcome

Several clinical variables have been identified to be associated with poor functioning in patients with bipolar disorder. In this study, low and high functioning groups differed significantly in the total number of episodes, depressive episodes, and time since the last episode. There was no difference in age at onset, total duration of illness, number of hospitalisations, or a history of psychotic symptoms. Total number of episodes, depressive episodes, and time since the last episode were significantly correlated with GAF score. Time since the last episode was the best predictor of psychosocial functioning.

The total number of episodes was associated with functional impairment. The mean total numbers of episodes were 9.2 and 5.7 in low and high functioning groups, respectively. Total number of episodes was negatively correlated with GAF score (Pearson's correlation $r = –0.459$,

p = 0.000). This finding is in line with earlier studies that reported a higher number of episodes has a more negative impact on social functioning.[5,29,30] It is possible that more episodes may cause long-lasting biochemical changes in the brain that may impact global functioning in bipolar patients.[31] Another possible explanation is that patients with multi-episode bipolar disorder are more prone to cognitive impairment that may in turn further worsen psychosocial outcome and employment.[32-34] Nonetheless this study did not determine the correlation of clinical variables with cognitive functioning. A further possible explanation is that recurrent mood episodes and longer active phase of illness result in interrupted educational and vocational pursuits and repeated disruption of interpersonal engagement.[35,36]

In this study the number of depressive episodes was more strongly correlated with functional outcome than manic and total number of episodes (Table 4). The mean numbers of depressive episodes were 4.9 and 2.2 in low and high functioning groups, respectively. Another study[5] showed similar findings where number of previous depressive episodes was a stronger determinant of outcome than past manias. Other studies[37,38] also found that depressive episodes are strongly associated with poor functioning in bipolar disorder. Another study[39] found that the number of manic episodes was associated with poor functional outcome only, but not the depressive episodes.

There are several possible explanations for the association between high rates of depressive episodes and impaired functioning. Some authors suggest that bipolar disorder patients perceive depressive phases as weaker than manic episodes.[40] Another possible explanation is that depressive episodes are often associated with cognitive impairment that may worsen global functioning along the course of bipolar illness. Alternatively, it is possible that functional impairment may itself have a role in the development of depressive relapses.[5]

In this study time since the last episode was the best predictor of psychosocial functioning in euthymic patients with bipolar disorder. Time since the last episode also differed significantly between low and high functioning groups (13.8 vs. 43.8 months). It was positively correlated with GAF score and indicates that the longer the time a patient in a euthymic state, the better the outcome. Thus, our study suggests that interventions directed at prevention of relapse into further episodes will result in better psychosocial outcomes.

Impact of Neurocognitive Performance on Functional Outcome

In the present study various neurocognitive tests were performed to assess the cognitive domains of executive functioning (interference Stroop Colour Test, Trail Making Test part B, digit span backward test), attention and concentration (digit span forward test, Trail Making Test part A), and verbal learning and memory (verbal learning and memory test) because these are among the most important cognitive domains for daily functioning.[41] Both low and high functioning groups performed poorer than the control group on the digit span backward test, Trail Making Test, verbal learning and memory test, and Stroop Colour Test. These findings show that euthymic patients with bipolar disorder have cognitive deficits in all the domains studied, i.e. executive functioning, attention and concentration, and verbal learning and memory. This is in accordance with existing literature. Meta-analytic studies suggest that euthymic patients with bipolar disorder have neurocognitive impairment in the domains of attention and processing speed, verbal learning, memory, and executive functioning.[17,42]

On post-hoc analysis, comparison between low and high functioning groups revealed that the former performed poorer in Trail Making Test and Stroop Colour Test. Furthermore digit span backward test, Trail Making Test (part A and B), and Stroop Colour Test were significantly correlated with GAF score and interference Stroop Colour Test was the best predictor of functional outcome. These findings show dysfunction in attention, psychomotor speed, working memory, ability to shift strategy, inhibitory control, and fluid cognitive flexibility cumulatively denote executive dysfunction in low functioning group. Thus, executive functioning is a better predictor of functional outcome than the other domains studied. These findings were supported by Martino et al[43] who found significant associations of functional capacity with measures of attention (digit span forward test, Trail Making Test part A) and executive functions (Trail Making Test part B, verbal fluency test) in a sample of 48 euthymic patients with bipolar disorder. Similarly, Mur et al[44] found that impaired executive function and loss of inhibition might be an important feature of bipolar disorder and suggested that these executive-type cognitive traits may constitute an endophenotype for further studies of the aetiology of bipolar disorder. Dixon et al[45] have observed a shared pattern of executive dysfunction in manic, depressed and euthymic patients, with respect to strategic thinking, inhibitory control and response initiation, independently of mood state, and it is now apparent that all 3 phases of the illness demonstrate cognitive deficits. In an Indian study by Trivedi et al,[46] euthymic bipolar patients showed significant differences in executive functions compared with normal controls.

Martinez-Aran et al[12] found that bipolar patients in general showed poorer cognitive performance than healthy controls. This was most evident in low functioning patients and particularly for verbal memory and executive function measures. The best predictor of psychosocial functioning was verbal memory.[12] Impaired attention and executive functioning can interfere with almost every facet of human life. Executive domains of cognition are required in every task of daily living. It is possible that cognitive impairment, especially in the executive domain, significantly disrupts functioning of patients, even in the euthymic phase. This poor functioning is one of the main factors that explains why bipolar disorder has been ranked seventh among the worldwide causes of non-fatal disease burden, as measured

in disability-adjusted life years by the World Health Organization.[47] Recent studies have highlighted the modest impact of available interventions on functional recovery for a large proportion of bipolar disorders,[48] and called for a research agenda that specifically addresses these issues.

The cognitive deficits that persist during the stable phase of illness, even after subsidence of active symptoms, suggest that some illness process is continued that was present before the illness was first diagnosed. Thus, our findings also indicate that these cognitive deficits may be considered endophenotypes of bipolar disorder. Bora et al[49] conducted a meta-analyses of 18 cognitive variables in studies that compared performance of euthymic bipolar disorder patients (45 studies; 1423 subjects) or first-degree relatives of bipolar disorder patients (17 studies; 443 subjects) with healthy controls and found that response inhibition deficit, a potential marker of ventral prefrontal dysfunction, was the most prominent endophenotype of bipolar disorder. This study provides some initial confirmatory evidence although further studies are required to establish these findings.

Limitations

The sample size was small so results cannot be generalised. The main limitation of the present study was the superficial separation of the patients into 2 groups based on a cut-off GAF score. Nonetheless it is probably useful to distinguish patients with no or mild impairment (high functioning group) in psychosocial outcome from those patients with severe or moderate impairment (low functioning group). Another relevant issue is the differences between patients and controls with respect to medication. This could partly explain the differences in neurocognitive performance. Although cognitive dysfunctions may be related to the effects of medication, they do not appear to be a primary effect of pharmacological treatment. The medication profile revealed that our patients were prescribed 4 kinds of medication: lithium, antiepileptics, antipsychotics (no patient was on conventional antipsychotics), and antidepressants. According to the literature there is no or little effect of medicines on cognition. With respect to lithium, a longitudinal study[50] showed stable cognitive performance over a 6-year follow-up period. Regarding antiepileptics, research has found only a little evidence of cognitive impairment.[51] Antipsychotics also have a neutral effect upon cognition, although some studies report improvement.[52] In this study mixed episodes were not included in the results and discussion because we found mixed episodes in few patients only and analysis was not possible with so little data. We were unable to determine the association between clinical variables and cognition.

Conclusions

The present findings suggest that cognitive factors and clinical variables related to illness severity contribute to psychosocial outcome in bipolar disorder. Total number of episodes, depressive episodes, and time since the last episode correlated with poor functioning. Long-term therapeutic interventions that target relapse prevention with special consideration given to depressive episodes are required. Cognitive dysfunction is also correlated with poor functioning. It was most pronounced in low functioning group, but also evident in high functioning group. Executive dysfunction seems to be a strong predictor of psychosocial outcome in euthymic bipolar patients. These factors should be considered more widely with respect to the long-term management of bipolar disorder. The current treatments for bipolar disorder patients are limited with regard to functional recovery. More focus should be placed on psychopharmacological as well as psychosocial interventions, such as psycho-education, family intervention, and cognitive rehabilitation targeting relapse prevention and cognitive improvement.

In future, longitudinal follow-up studies with improved methodology and larger sample size could be planned to assess the progression of illness and cognitive dysfunctions and their impact on psychosocial functioning, as well as to establish the therapeutic efficacy of newer interventions that target relapse prevention and cognitive enhancement.

Declaration

The authors have disclosed no conflicts of interest in this study.

Abstract

Background: Attitudes and belief toward mental illnesses are important factors that affect perception of mental health. Knowing the attitude of medical students towards psychiatry and mental illnesses is of utmost importance as they are future care provider. Current study is conducted to assess the attitude of medical students towards mentally ill patients and mental illnesses, to identify correlation of attitude score with personal and family history of mental illness and, to compare the score among students of the three year-wise groups.

Method: The study population included 219 students of first, second and third professional MBBS. We designed an online data collection tool and executed it using the Google Forms. The Google Form link to the questionnaire was sent to the enrolled participants via the identified WhatsApp groups or individual number. Beliefs toward Mental Illness (BMI) scale was used to assess attitude towards mental illnesses which is a 21-item self-report measure of negative stereotypical views of mental illness. The results of the study were examined and analyzed by using Statistical Package for Social Sciences (SPSS 25.0).

Results: Out of total 21 items of the BMI scale, students showed positive attitude on majority of items. The mean score for BMI scale and per item mean score for the scale were towards positive attitude. Majority of students agree that a mentally ill person is more likely to harm others than a normal person and that mental disorders would require a much longer period of time to be cured than would other general diseases. Higher per item mean score for dangerousness and, incurability subscale showed their negative attitude. An increasing trend of positive attitude has been seen with an increase of education level and exposure towards the subject.

Conclusions: Medical students show variable scores on belief towards mental illness scale, its subscales and, individual items. Admitting this prevailing stigma needs to be acknowledged and openly discussed with medical students in order to overcome these views. Providing adequate education on mental illnesses and attached negative attitudes or myths can change these negative beliefs.

Keywords: Medical students, psychiatry, mental illnesses, stigma, dangerousness.

1. Introduction:

Attitudes and belief toward mental illnesses are important factors that affect perception of mental health. The prejudiced and negative attitudes or stigma towards people with mental illness are widespread. In our society, health professionals have similar views about those with mental health problems and mentally ill patients. Literature suggests that people diagnosed with mental illness are considered by the majority of the society as people who are dangerous, loathed, stranger and somebody whose actions cannot be predicted.[1] Globally, psychiatry as a subject, psychiatrists as professionals, and patients with psychiatric disorders are subjected to cultural stereotypes and negative attitude by the general population. What is of alarming concern is that these prejudices exist within the medical community as well.[2-6] Stigma toward mental illness is an influential factor leading to negative views among medical students toward psychiatry. Lack of knowledge and awareness about mental illnesses among the students is associated with the negative attitudes towards mental illness in the community. For medical students during their training, educational intervention targeted towards these negative attitudes may be more effective than doctors who have already completed their training because research has shown as they carry on through their career, their attitude harden and become more resistant to change.[7] The concept of iatrogenic stigma is used to describe the stigma caused or perpetuated by mental health professionals.[8] This stigma and negative attitudes can affect the quality of life for people with mental illness. There may be various reasons for this negative attitude such as lack of accurate information about mental illness and lack of contact with individuals with mental illness.[9]

While some studies have suggested that aspiring young doctors have a favorable opinion about psychiatry as a branch[10], other studies have suggested that medical students' attitude toward psychiatry is unfavorable.[11-17]

A doctor's attitude towards persons with psychiatric illness and psychiatry should involve an impression of an empathetic listener and should have non-judgmental approach. Knowing the attitude of medical students towards psychiatry and mental illnesses is of utmost importance as they are future care provider. To improve psychiatric training in this population beliefs and attitude toward psychiatric illnesses and need to be assessed and understood.

The reasons for studying the attitude specifically among medical students are that firstly as a doctor they can play an important role in decreasing negative attitude and, secondly the results from the study will help to focus strategies to change attitudes of this group. The comparison among various groups in present study will help in understanding the impact of successive undergraduate training years. The findings may help in understanding the various points of strength and lacunae in the current undergraduate curriculum regarding mental health.

Objectives:

The objectives of the current online study were-

1. To assess the attitude of medical students towards mentally ill patients and mental illnesses
2. Correlation of attitude score with personal and family history of mental illness, and
3. Comparison among students of the three year-wise groups.

2. Methodology

Study population and study area: The study population includes all the students who have

enrolled in MBBS course (first year, second year and final year) at Ananta Institute of Medical Science and Research Centre, Rajsamand, Rajasthan. Those students who will give their consent to participate in the study will be included and rests will be excluded at their will.

Study Duration: one year, June 2020 to May 2021.

Sampling techniques and sample size

Samples were obtained using stratified random sampling method. The 3 batches of medical students viz first year professional, second year professional and third year professional which were considered as strata collectively develop a sampling frame of 450 students. The minimum sample size on assumption of 95% level of significance, 5% error and 85% expected proportion was 196. After 12% adjustment of non- responders' students the final sample size was 219.

Undergraduates in the 1st year had not received formal exposure to psychiatry yet, students of 2nd year also have not attended clinical posting or lecture in psychiatry while students of Final year students had completed clinical posting and theory lectures in psychiatry. The institute is having well-functioning psychiatry department with adequate teaching staff and a good in-flow of patients in the psychiatry OPD as well as inpatient department.

Study procedure and statistical Analysis: After unlock 1.0 was announced by the Government of India from 8th of June 2020, the cases of COVID-19 were increasing all over India including Rajasthan. Hence there was risk of disease transmission by taking interview in person therefore we decided to use WhatsApp Messenger for enrolling potential participants and Google forms for filling up their response. The study was approved by institute ethics committee.

Tools: We designed an online data collection tool and executed it using the Google Forms (via docs.google.com/forms). The Google Form link to the questionnaire was sent to the enrolled participants via the identified WhatsApp groups or individual number.

Socio-demographic variables included age, gender, marital status, background, past personal history of mental illness, known history of mental illness in the family were described using descriptive statistics.

Beliefs toward Mental Illness (BMI) scale was used to assess attitude towards mental illnesses. The BMI scale is a 21-item self-report measure of negative stereotypical views of mental illness. (18) There is a total Score and the score of three sub-scales based on factor analysis: dangerousness, poor social and interpersonal skills, and incurability. There are five items in subscale dangerousness, ten items in poor interpersonal and social skills scale and six items in incurability subscale. Items are rated on a six-point Likert scale ranging from 'completely disagree' (0) to 'completely agree' (5), with higher scores reflecting more negative beliefs. In the primary validity study, Cronbach's alpha was high among American (0.89) and Asian students (0.91). The measure holds promising evidence of validity.

The results of the study were examined and analyzed by using Statistical Package for Social Sciences (SPSS 25.0). The categorical variables were described by numbers and percentages while continuous variables were described by average and standard deviation. Normality of attitude was checked using Kolmogrov-Smirnov test. After testing normality condition, the association and relationship between the variables were tested Pearson correlation by Student's t test and one way analysis of variance (ANOVA). The level of significance was considered at $P<0.05$.

3. Results

A total 219 number of students were participated in the online study. The sample comprised of 41.55% of male students and 58.44% of female students. Majority of the students were unmarried (97.26%), belonging to urban background (79.45%), having negative past personal history of psychiatric illness (86.75%) and negative family history for psychiatric illnesses (75.79%).

Table 1: Socio-demographic characteristics of respondents

Variables	Participants N (%)
Sex	
Male	**91 (41.55%)**
Female	**128 (58.44%)**
Marital Status	
Married	**6 (2.73%)**
Unmarried	**213 (97.26%)**
Place of residence	
Urban	**174 (79.45%)**
Rural	**45 (20.54%)**
MBBS Batch	
First year professional	**49 (22.37%)**
Second year professional	**138 (63.01%)**
Third year professional	**32 (14.61%)**
Had mental illness in past:	
Yes	**29 (13.24%)**
No	**190 (86.75%)**
Is someone in your family/ friends/ relative is having mental illness:	**53 (24.21%)**
Yes	**166 (75.79%)**
No	
If yes, then	
Friends	**7(13.2%)**
Family	**26(49.05 %)**
Relative	**20(37.73%)**

Table 1 shows socio-demographic characteristics of respondents.

Attitudes of students towards mental illness

0 = Completely disagree, 1 = Largely disagree, 2 = somewhat disagree, 3 = somewhat agree, 4 = Largely agree, 5 = Completely agree

Table 4 shows item wise responses and percentage of participants regarding statements on the beliefs about mental illness on incurability subscale of the BMI scale

b) Attitudes by Subscale

There are five items in subscale dangerousness, ten items in poor interpersonal and social skills scale and six items in incurability subscale.

Table 5: Per item Mean and 95% CI for the three subscale and overall score of BMI scale

Subscale	**M(SD)**	**95 %CI**
Dangerousness	2.17(0.90)	2.77, 1.56
Poor interpersonal and social skills	1.77(0.92)	2.99, 0.54
Incurability	2.21(0.92)	2.94, 1.47
Full BMI scale	1.99(0.80)	4.22, -0.24

* M- Mean, SD- Standard deviation, CI- Confidence interval

Table 5 shows per item mean and 95% confidence interval for the three subscales and overall score of BMI scale.

c) Associates of attitudes

The differences in the attitude scores in different independent variables have two categories were determined by independent sample t tests. And, difference in attitude score in independent variables having more than two categories was determined by the one-way ANOVA.

As per Kolmogrov-Smirnov test statistic (D)results in 0.04762 which means that data is normally distributed. So independent sample t test has been applied to find out difference in attitude score by socio demographic characteristics.

Table 6: Difference in attitude score by socio-demographic characteristics

Characteristics	M(SD)	Diff.*(95% CI)	p-value
Sex			
Male	42.67(17.20)	1.24(-3.31,5.79)	0.59
Female	41.43(16.61)		
Marital status			
Married	60.17(9.06)	18.73(5.20,32.27)	**0.007**
Unmarried	41.43(16.72)		
Place of residence			
Urban	42.80(16.32)	4.18(-1.35, 9.71)	0.13
Rural	38.62(18.48)		
Had mental illness in past			
Yes	40.10(15.14)	2.12(-4.50, 8.74)	0.52
No	42.23(17.09)		
Is someone in your family/ friends/ relative is having mental illness:			
Yes	39.64(17.34)	3.03(-2.19, 8.27)	0.25
No	42.68(16.65)		

*Diff. =Difference in mean, (lower bound, upper bound)

Table 6 shows difference in attitude score by socio-demographic characteristics. Married students (N=6) had higher BMI score than unmarried students (N=213) and the difference was statistically significant. On further analysis it was found that of these six married students, five had positive response for history of mental illness in family, friend or any relative, also two had positive history of past mental illness. The difference among groups was not statistically significant for other characteristics.

Table 7: Difference in attitude towards mental illness by education level of students

Characteristics	M(SD)	F- value	p-value	p-value trend
Batch		9.11	**<0.0001**	**<0.0001**
I MBBS	48.11(14.34)			
II MBBS	43.63(14.71)			
III MBBS	41.08(15.21)			

*M= mean, SD= standard deviation, F=degree of freedom, p= p value

Table 6 shows that There is increase trend in positive attitude in medical students with increase in their education level ($p<0.0001$).

There was significantly positive attitude towards mental illness among III MBBS students than II MBBS and, among II MBBS than I MBBS ($p<0.0001$). An increasing trend of positive attitude has been seen with an increase of education level and exposure towards the subject.

4. Discussion

The current online study was planned to assess the attitude of medical students towards mentally ill patients and mental illnesses, to find correlations of attitude score with sociodemographic and clinical variables and, to compare the score among students of the three year-wise groups.

Out of total 21 items of the BMI scale, students showed positive attitude on majority of items (fifteen items) and negative attitude on few items (six items). The mean score for BMI scale was 41.99 and per item mean score for the scale was 1.99. This score is towards positive attitude. Jilowa et al also found in their study that Nearly 84% of second-year medical students and 52% of interns had positive attitude toward psychiatry. (19) In their study, Risal et al also found overall positive or neutral attitudes towards mental illness and psychiatry among the medical students and interns in their institute. (20)

In our study we found that majority of students agree that a mentally ill person is more likely to harm others than a normal person (64%) and that mental disorders would require a much longer period of time to be cured than would other general diseases (83%). Kodakandla et al conducted a study on Attitude of interns towards mental illness and psychiatry and found that majority of the interns believed that mentally ill person is more likely to harm others and that mental illness require a much longer time to be cured than other general diseases. (21) In our study majority (58 percent) of students agree that most people would not knowingly be friends with a mentally ill person. Jyothi NU et al also found majority (96 percent) of participants agreed with the statement. (22)

In our study we found that majority of students agree that psychological disorder is recurrent (64%), that people who have once received psychological treatment are likely to need further treatment in the future (61%), and that the behaviour of people who have psychological disorders is unpredictable (65%). Kodakandla et al also found that majority of participants (76%) believed that psychological disorder is recurrent and that the behavior of patients with psychological disorder is unpredictable (79%); two third of them (68%) were of the opinion that people who have once received psychological treatment are likely to need further treatment in the future. (21) Jyothi NU et al also found similar findings in a study on college students. (22)

Students showed per item mean score 1.77 for poor interpersonal and social skill subscale which is towards positive attitude. Higher per item mean score 2.17 for dangerousness subscale and 2.21 for incurability showed their negative attitude. In a community Study on Attitudes to and Knowledge of Mental Illness in Tehran, Ghanean H et al found that around half participants agreed that people with a mental illness “are dangerous”. (23) Contrary to our findings *Kodakandla et al* found that only one third (31%) interns believed that psychological illness is unlikely to be cured regardless of the treatment. (21)

Married students showed statistically significant higher BMI score compared to unmarried students. On further analysis it was found that of these six married students, five had positive response for history of mental illness in family, friend or any relative and, two had positive history of past mental illness. So,

these two factors might have caused higher stigma in this small sample. The attitude score was not associated statistically significantly with other sociodemographic and clinical variables.

There was significantly positive attitude towards mental illness among III MBBS students than II MBBS and, among II MBBS than I MBBS ($p<0.0001$). An increasing trend of positive attitude has been seen with an increase of education level and exposure towards the subject. Similar to our study Aruna et al also highlighted exposure to psychiatry could improve the knowledge base of medical students. (24) Tharyan et al also found that psychiatric education positively influences the attitudes of medical students towards mental illness and some aspects of psychiatry. (25) However, providing clinical training in psychiatry during under graduation seems to improve the attitude toward people with mental illness. (16, 25-27) The favorable impact of psychiatry posting on the attitude of medical students towards mentally ill has been found in previous studies from western countries. (28) Work by Mas and Hatim (2002) from Malaysia found that final year MBBS students had more favorable attitude towards mentally ill as compared to the first-year students. (29)

The National medical commission (formerly Medical Council of India) has implemented Attitude, Ethics and Communication module (AETCOM) in all medical colleges in India in August 2019. (30) The cognitive components, behavioural attitudes and ethical dimensions of AETCOM module will change the approach of future doctors to psychiatry and person with psychiatric illness. Focusing more on clinical exposure and skills the new competency based medical education (CBME) programme has increased the duration of undergraduate clinical posting to total four weeks and total 40 hours for teaching from two weeks and 25 hours pre CBME respectively. This sequential introduction of clinical posting during second professional MBBS followed by theory class and clinical posting during third MBBS part-I will be more helpful in understanding of the subject. In future, mandating psychiatry as an independent subject of examination in under graduation assessment may prove a milestone step in medical education. So, it may be expected that this increased exposure will help in removing the existing negative attitudes towards psychiatry and person with psychiatric illness.

Suggestions:

Admitting the prevailing stigma needs to be acknowledged and openly discussed with medical students in order to overcome these views. Prevailing stigma and the negative attitudes about mental illnesses affect both patient caring and psychiatry as a career choice. The development of educational strategies enabling initial interest shown during the early clinical exposure needs to be maintained. Providing public education on mental illnesses and attached negative attitudes or myths can change these negative beliefs in general public. To promote psychiatry as a career, interested students need to have increased access to an in-depth experience of psychiatry, including “enrichment activities” such as electives in psychiatry.

Conclusions:

Medical students show variable scores on belief towards mental illness scale, its subscales and, individual items. Admitting this prevailing stigma needs to be acknowledged and openly discussed with medical students in order to overcome these views. Providing adequate education on mental illnesses and attached negative attitudes or myths can change these negative beliefs.

Implications of the Study:

This study will help in understanding of belief of medical students towards mental illnesses. The comparison among various groups in

present study will help in understanding the impact of successive undergraduate training years.

Limitations:

This was a cross sectional study with small sample size.

Future Direction:

Future studies can be undertaken with large sample size to determine the changes in belief of medical students admitted year 2019 onwards.

Acknowledgement:

Our sincere thanks to Dr. Manoj Jani and all participants.

Abstract
Background: psychological methods are less commonly used in treatment of psychiatric illnesses in hospital setup. In some psychiatric illnesses drug use has limiting effect in full cure of illness due to psychosocial dynamics associated with those illnesses.
Aim: In dissociative conversion disorder one theory states that primary gain is conversion of mental or emotional feeling into physical symptoms and secondary gain is any other external benefit from physical symptom occurred in primary gain. Like in a disturbed marital conflict wife develops episodic unresponsiveness (pseudo seizures) as primary gain and revived attention and care of husband due to this episodic unresponsiveness (pseudo seizures) as secondary gain. It is hypothesized that dissociative conversion reaction develops and become resistant by getting these two primary and secondary gains. Our study aim at providing unpleasant mild aversive electric current to the subjects along with standard pharmacotherapy to make patient condition to this painful stimulus and end their maladaptive behavior.
Material and Methods: Structured Clinical Interview for DSM-5 was used for making diagnosis and Dissociative Experiences Scale and Global Assessment of Functioning (GAF) for evaluating the response of treatment. Mild electric current (30 mili columb) was used in test group along with standard treatment group.
Results: In test group improvement in terms of Dissociative Experiences Scale and Global Assessment of Functioning (GAF) and number of episodes of unresponsiveness was better.
Conclusion: Use of mild electric current as aversive stimulus as compared to standard treatment group was found more affective mode of treatment
Keywords: dissociative, conversion, aversion therapy, pseudo seizures, electric current

Introduction

Conversion reaction (functional neurological mental disorder) is mental illness in which sensory and motor abnormality is seen without any focal physical or nervous system lesion. According to DSM 5 following diagnostic criterion are included[1]

1-one or more symptoms of altered voluntary sensory or motor functioning

2-clinical findings provide incompatibility between symptoms and recognized neurological condition

3- Symptoms not explained by other physical or mental condition

4-Symptoms producing significant distress in social, occupational or emotional and other area of functioning

Aversion therapy is a type of behavioral therapy that make patients give up their undesirable habit by causing them to associate it with a distressing event. This conditioning is meant to cause the patient to associate this stimulus with unpleasant type of sensations with the intention of stopping the targeted unwanted behavior. Aversion therapies can be of many types, like using unpleasant-tasting substances ie chili or denatonium benzoate on the fingernails to discourage nail biting[2]; pairing of some painful event with undesired behavior, pairing the use of an emetic substance with alcohol[3] or pairing unwanted behavior with electric shocks[4].

Pattern of use of aversion can be

1-Negative reinforcement (a.k.a. escape). In this type of reinforcement pattern aversion stimulus is removed after occurrence of the particular desired behavior. In the Skinner Box experiment, the aversive stimulus might be an electric current continuously inside the box; negative reinforcement would happen when the rat presses a lever to turn off the current. This is also known as escape learning[5].

2-Positive punishment ("punishment") when an aversive stimulus is provided to stop some undesired behavior. like in skinner box aversive stimulus will be a shot of current if

it goes to a particular chamber to stop rat entering in that specified box chamber [6].

It is evident from review of journals published in Indian Journal of Psychiatry (IJP) that only about 2% related to use of psycho-social methods of treatment, in comparison to 16% that are published in the British Journal of Psychiatry[7]. It signifies that most psychiatrist in India relay mostly on pharmacological methods of treatment and psychological methods to treat psychiatric illnesses are mostly ignored. This study was planned to incorporate psychological principals in treatment psychiatric illnesses with pharmacological treatment plans to maximize the treatment benefit[8].

Material and Methods

DSM-5 was used for making diagnosis and Dissociative Experiences Scale and Global Assessment of Functioning (GAF) and World Health Organization Quality of Life (WHOQOL)-BREF for evaluating the response of treatment. Mild electric current (30 mili columb) was used in test group along with standard treatment group.

DSM 5 criterion of conversion reaction was used including four criterion

A-One or more symptoms of altered voluntary sensory or motor functioning

B-Clinical findings provide incompatibility between symptoms and recognized neurological condition

C- Symptoms not explained by other physical or mental condition

D-Symptoms producing significant distress in social, occupational or emotional and other area of functioning

Global Assessment of Functioning, or GAF, scale is used to rate the seriousness of mental illness. It use to measure how much a person's mental illness symptoms affect his or her daily life on a scale of 0 to 100[9]. It is a continuous scale and measure psychological, social and occupational impairment due to mental illness. Physical and environmental functioning not rated on it.

100-91	Superior functioning in wide range
90-81	Absent and minimal symptoms
80-71	Transient symptoms
70-61	Some mild symptoms
60-51	Moderate symptoms
51-41	Serious symptoms
40-31	Impairment in reality testing
30-21	Delusion and hallucination present
20-11	Some danger of self /other harm
10-01	Persistent danger of self/ other harm
0	Inadequate information

MICHELE A. PACKARD, suggests that

GAF Score 1 – 30 the patient is a candidate for inpatient care and need high level of psychiatric /psychological help

GAF Score 31 - 69 the patient is a candidate for outpatient care –for pharmacotherapy/psychotherapy

GAF Score 70 - > In most cases, no treatment is needed because the patient is functioning too well to be a candidate for any therapy.

If after getting treatment of one month GAF score of a patient become more than 70, it will be considered as improvement in our study

The World Health Organization Quality of Life (WHOQOL)-BREF

The WHOQOL-BREF has broad groups one is Overall quality of life (QOL) and other is General Health and 24 items divided into four major domains: Physical health domain comprising 7 items (DOM1), psychological health domain contains 6 items (DOM2), social relationships domain contains 3 items (DOM3) and environmental health domain contains 8 items (DOM4)[10].

Statistical analysis

Our research data was analyzed using graphpad instat and spss software. The Student t test was applied to derive statistical significance between compared groups. Division of study (50) and control group (50) was based on simple computer randomization.

Results

By using self-developed socio-demographic profile for data extraction table 1 is made by incorporating the data in appropriate classification module.

Table 1: Sociodemographic features

		Study group n=50	Control group n=50

Score on 1 month(mean±SD)	67±4	80±4	0.0001

Discussion

It is evident from study results on global assessment of functioning there is improvement after one month of treatment. If we compare control and study groups on global assessment of functioning we can see that improvement after incorporation of aversion therapy was more as compared to control group.

Comparison on world health organization World Health Organization Quality of Life (WHOQOL)-BREF scoring demonstrate the same finding that there is improvement after one month of treatment in both control and study group, and same time the improvement in study group receiving aversion therapy along with standard pharmacotherapy was more.

Conclusion

Aversion therapy when coupled with standard pharmacotherapy is more effective in treatment of conversion reaction related pseudo-seizures. It is than recommended to try as a non-harmful and cost effective way of treatment

A Prospective Study on Association of Social Anxiety in Patients Suffering from Various Clinical Presentations of Acne Vulgaris

Bharat Agarwal

Assistant Professor, Department of Psychiatry, Ananta Institute of Medical Sciences and Research Centre,Rajsamand, Rajasthan, India.

ABSTRACT

Background: *Acne vulgaris is a common illness of adolescence. During adolescence, the importance of body image and the cosmetic problems that this illness may cause, it is important that the level of social anxiety should be studied in acne patients.*
Methods: *100 acne vulgaris cases were included in this study. This study conducted in the department of Psychiatry in Ananta Institute of Medical Sciences and Research Centre. The duration of study over a period of six month.*
Results: *This study showed that amongst acne patients having social anxiety majority had acne lesions localized on face (36,7%), almost all had clinically very severe (100%) acne and none of them subjectively perceived their acne lesions as mild.*
Conclusions*: This study concludes that, clinician's evaluation is objective and more precise and valuable, but the self-perception of a patient has a greater effect on his/her psychological condition.*

Keywords: *Acne vulgaris, Social anxiety, Psychiatric disorders*

INTRODUCTION

There are several researches on the relationships between dermatological illnesses and psychiatric disorders for a long time. But a few studies have been done on the role of psychological factors on dermatological illnesses.[1] It has been observed that psychiatric and psychological factors play a role in at least 30% of dermatological patients.[2] Apart from this, dermatosis seems to have psychological consequences.[3] Skin diseases may lead to anxiety, depression, or other psychological problems to the same degree as illnesses like arthritis, which may lead to disability. Various factors which are concerned with the patient and illness, such as gender, age, and lesion localization, play a vital role.[4]

It is well known that acne is a chronic inflammatory disease. It is characterized by lesions, such as pilosebaceous gland comedones, papules, pustules, and nodules. Mostly, it starts during adolescence and regresses during the mid-20s. It is more common and severe in males.[5] It has been estimated that almost 85% of adolescents and young adults are in some way affected by it.[6] Among the skin diseases, acne is the most frequently encountered disease. The relationship between acne and psychological factors has been

investigated for a very long time. Emotional stress can aggravate acne. As a result of having acne, patients may experience psychological and psychiatric problems.[7]

The importance attributed to the theories about the role of psychogenic factors in the pathogenesis of acne is gradually decreasing. The effect of acne on patient emotional wellbeing is still an investigation topic, though research results are inconsistent.[8] Although there are numerous studies that debate the psychological problems and psychiatric symptoms that result from acne. Social anxiety and its related factors have not been studied adequately. Acne vulgaris is a common illness of adolescence. During adolescence, the importance of body image and the cosmetic problems that this illness may cause, it is important that the level of social anxiety should be studied in acne patients.

The purpose of this study was to determine the level of social anxiety in acne patients and to examine its relationship to socio demographics, clinical features, depression symptoms, self-esteem, and negative automatic thoughts.

METHODS

Study population: - 100 acne vulgaris cases were included in this study.

Study Area: - This study conducted in the department of Psychiatry in Ananta Institute of Medical Sciences and Research Centre

Study Duration: -The duration of study over a period of six month.

Data collection: - These patients with definitive diagnosis of acne vulgaris were referred to psychiatrist for further assessment. After exclusion of co-morbid medical and dermatological and pre-existing psychiatric disease taking detailed history; 100 consecutive patients with definitive diagnosis of acne vulgaris, were briefed about the study and recruited after obtaining written informed consent. They were asked to subjectively rate their acne severity on visual analogue scale (VAS). Level of social anxiety was assessed using Liebowitz Social Anxiety Scale (LSAS). Acne related clinical variables (site of lesions, clinical and subjective severity) were noted on specially designed semi structured Performa.

Data analysis:- Data were analyzed by using Microsoft excel.

RESULTS

In our study, 100 total numbers of cases were included. Out of 100, 49% were belonging to 21-25 age group followed by other age group. In the present study,36% had social phobia,39% social anxiety & 32% social avoidance. This study showed that amongst acne patients having social anxiety majority had acne lesions localized on face (36,7%), almost all had clinically very severe (100%) acne and none of them subjectively perceived their acne lesions as mild. However, these clinical variables of acne had statistically non-significant impact on presence of social anxiety.

Table 1: Distribution of cases according to age

Age Group	No. of cases	Percentage
15-20	17	17%
21-25	49	49%
26-30	34	34%
Total	100	100%

Table 2: Distribution of cases according to social anxiety

Social anxiety	No. of cases	Percentage
Social phobia	36	36%
Social Anxiety	39	39%
Social Avoidance	32	32%

Table 3: Impact of clinical variables of acne on social anxiety according to Localization

Localization	LSAS more than cut off Social Anxiety	
	Yes	No
Mostly on Face	33	57
Mostly on Body	2	5
Equally distributed	1	2

Table 4: Impact of clinical variables of acne on social anxiety according to GAGS

Clinical Acne Severity by GAGS	LSAS more than cut off Social Anxiety	
	Yes	No
Mild (1-18)	12	17
Moderate (19-30)	16	38
Severe (31-38)	4	9
Very severe (>39)	4	0

DISCUSSION

The present study was a cross sectional study. This study consisted of 100 consecutive patients diagnosed with acne presenting to dermatology OPD. The age group of 15-30 years was assessed for social anxiety after exclusion of other dermatological, medical and pre-existing psychiatric disease. When the importance of body image and resultant cosmetic problems is considered, it will definitely have impact on level of social anxiety in acne patients. Similar results were found in a study done by Yarpuz AY et al using LSAS, reported that 25.6%, 32.9%, 27.7% of the acne patients scored above the cut-off point of LSAS total scores, LSAS-Anxiety and LSAS-Avoidance subscale respectively.[9] the occurrence of acne in adolescence is at its peak and this is the time when teenagers are learning to form relationships. So, the level of social anxiety is high at this time. Therefore, acne patients may lack the self-confidence to go out with friends and make these bonds. This problem can lead to negative appraisal, feeling of shame and social uneasiness that they would be judged as unattractive by others. Further, they can develop social anxiety and social avoidance and in extreme cases social phobia also.

Ritvo E et al, conducted a survey by interviewing teens they observed that most of the teen respondents who had acne, stay off facebook for a year (59%) or not go on a date for a year (30%).[10] When acne localizes primarily on the face, it has a greater effect on psychological functioning. It causes less distress when it is on the back or the chest, it can be covered with clothing. Korczak et al, showed that frequent recurrence can result in disappointment of acne sufferer especially when lesions are on face.[11] This study found

statistically no significant difference between 3 localization group (face, body and equal distribution) amongst patients with acne having social anxiety. A study by Gupta et al reported that the patients with mild-moderate acne severity experience stress and had social anxiety. Results concluded that for acne to lead to psychological problems it need not be severe.[12] These findings contrast with the findings of our study, in which acne patients having social anxiety had clinically very severe (100%) acne. In another study it was found that patients evaluate the severity level of acne, especially when localized on the face.[13]

CONCLUSION

In the present study out of 100 patients of acne vulgaris, 36% had social anxiety. Patients with clinically and subjectively perceived severe acne had more social anxiety. Though a clinician's evaluation is objective and more precise and valuable, but the self-perception of a patient has a greater effect on his/her psychological condition.

Abstract
Background: Spirituality is a theme of religion and philosophy, which are Humanities and work on empirical principals. Psychology and psychiatry are developed from philosophy but have scientific attitude. Patient care is a complex issue and needs conversion of both of these principles.
Aim: We made an attempt to evaluate that use of spirituality principles in patient's treatment is helpful or not.
Material and methods: Total 510 patients were evaluated. Study group of 260 patients were given spiritual consideration in standard treatment and control group of 250 patients were only given standard treatment. World Health Organization Quality of Life (WHOQOL)-BREF raw score were compared using student t test.
Results: We found that there was significantly more improvement in study group as compared to control group in terms of World Health Organization Quality of Life (WHOQOL)-BREF score.
Conclusion: We arrived at the conclusion that spiritual consideration gives added improvement in treatment of psychiatric illnesses. We should not ignore spiritual beliefs of patients.
Keywords: spirituality, beliefs, psychiatric illness, psychology

Introduction:

Science in itself always use to challenge the existence of god or super natural power, but in every culture there are belief systems which are deeply rooted in spiritual beliefs. Many times these belief systems make persons belief firmly that a particular type of illness is a result of some super natural power like god or demon. This belief can hamper improvement in psychiatric illness on treatment. Psychiatry as a science denies existence of such super natural causes of illness in first glance as a branch of science, but this ignorance creates a grey area where unscientific treatment methods and faith-healing blossom. Religious belief in faith-healing does not depend on any scientific evidence that this can achieve any evidence-based outcome (*Village, Andrew 2005*). If a patient is willing to opt for faith-healing, a psychiatrist has options like one can reject the request, can keep oneself detached from the issue, approve the request and try to understand the practices concerned so as one can make a reasoned decision (Sarkar S, Seshadri 2015). But the choice is mostly towards rejection of request due to lack of understanding of spiritual angle of the treatment.

Some studies show that prayers for patients can speed up their recovery from illnesses (3). Faith healing practices are associated with improving mental well-being (4). On the same ground a systematic review failed to establish that distant healing can be achieved by prayer(5). In this regard despite weak evidence that prayers and faith-based practices have a therapeutic effect, the psychological benefit of such interventions cannot be ignored(6). One study of physicians and patients in an outpatient setting found that 91 percent of patients believe in God, compared with 64 percent of physicians(7).

There is no need to challenge or accept faith-healing on scientific grounds, if it benefits patient even in a minor fraction without any harm, it can be welcomed. Psychotherapy deals with changing maladaptive thoughts to healthy one and for this using spiritual belief system is not a sin. So the thought of spiritual counselling comes in mind. Spiritual counselling is a psychological tool which uses person's spiritual belief system for mental healing.

Western scientific principal that is more modern, denies traditional methods as non-scientific (8) but in highly spiritual countries where spiritual beliefs are so dominating one cannot ignore them in whole. Studies

say that spiritual assessment of patient not only fastens patient's healing but also strengthen the bondage between doctor and patient (9)

Material and Methods

Participants and procedures

Our study was conducted in Udaipur district of Rajasthan, India. In this region people of various religions i.e. Hindu, Muslim, Sikh and Jain are in good number and have high faith in religious rituals. A stratified random sample design was used for data collection and conducting study. HOPE questions and The World Health Organization Quality Of Life (WHOQOL)-BREF were applied at 0, 1 and 6 months interval. Our study spanned 6 months. Total 610 persons visiting in outpatient department (age range 18 to 60) were evaluated. 100 were excluded because they had low score on spirituality scale (HOPE question). Out of this 260 adults were included in study group and 250 in control group. Study group was allowed to incorporate spiritual methods of their own choice in treatment. Control group was strictly refused to go for any type of spiritual treatment (faith healing, prayer, sacred place visit, meeting spiritual guru, etc). Along with this both the groups received standard psychiatric treatment for their disease. Informed consent and ethical committee approval was taken accordingly.

Data collection tools

1. HOPE questions-The HOPE questions were developed as a tool to help practicing doctors begin the process of incorporating a spiritual assessment into the medical interview of their patients. These questions have not been validated by any research. The strength of this approach is that it allows exploration of an individual's general spiritual beliefs and concerns and serves as natural follow-up to discussion of other spiritual support systems (10). The HOPE questions cover the basic areas of inquiry for doctors to use in formal spiritual assessments of their patients

HOPE Approach to Spiritual Assessment

a) Spiritual Resources - What are your sources of hope or comfort?
b) Organized Religion - Are you a member of an organized religion?
c) Personal Spirituality - Do you have spiritual beliefs, separate from organized religion?
d) Effects on Care - Do you wish to consult with a religious or spiritual leader when you are ill or making decisions about your healthcare?
2. The World Health Organization Quality of Life (WHOQOL)-BREF

The WHOQOL-BREF has two items from the Overall QOL and General Health and 24 items divided into four domains: Physical health 7 items (DOM1), psychological health 6 items (DOM2), social relationships 3 items (DOM3) and environmental health 8 items (DOM4)(12).

Statistical analysis

Data was analyzed using graphpad instat and SPSS software. Student's t-test was applied to derive statistical significance.

Results

Self-developed socio-demographic profile was used for data extraction. Table 1 incorporates the data in appropriate classification module.

Table 1: Sociodemographic features

		Study group n=260	Control group n=250
Age (mean±SD*)		29±6	30±7.2
Sex	Male	142 (54.6)	136 (54.4)
	Female	118 (46.4)	114 (46.6)
Religion	Hindu	210 (80.7)	240(96)
	Muslim	49(18.9)	20(4)
	Other	1(0.4)	0(0)
Education	Illiterate	69(26.2)	12(4.8)
	undergraduate	140(53.8)	182(72.8)
	Graduate	52(20)	56(22.4)

*SD – Standard deviation

Persons with high spirituality based on HOPE questionnaire were included and persons with low spirituality were excluded from the study.

	Included in study	Excluded from study	
Subjects	510	100	
HOPE questionnaire response	Spiritual	Non spiritual	
World Health Organization Quality of Life (WHOQOL)-BREF			
	Study group N=260	Control group n=250	P value
Score at 0 month (mean±SD)	45±7	44±9	0.1610
Score at 1 month (mean±SD)	62±4	52±5	0.0001
Score at 6 month (mean±SD)	72±5	60±7	0.0001

Discussion

The study was planned to see the effect of spiritual belief consideration in improvement of psychiatric patients. The persons were first screened for having spiritual beliefs by using HOPE questions. Persons low on spiritual beliefs was excluded from the study. Included patients were classified in study group and control group on the basis of random classification. Study group patients were allowed to use their spiritual methods of treatment along with standard drug treatment provided to them. Control group patients were denied of having any spiritual treatment of their choice and only provided standard drug treatment. Both the groups were provided standard drug treatment based on their respective classification according to international classification of disease 10 (ICD 10).World Health Organization Quality of Life (WHOQOL)-BREF scoring at 0, 1 and 6 month demonstrated gradual improvement in terms of World Health Organization Quality of Life (WHOQOL)-BREF score in control and study groups. Analysis demonstrated more improvement in study group as compared to control group. This difference was statistically significant and not a spurious finding.

Conclusion

This study demonstrated clear cut improvement in study group (62±4) as compared to control group (52±5) after 1 month of treatment. It also demonstrated improvement in study group (72±5) as compared to control group (60±7) after 6 months of treatment. Both the results were statistically significant with p value of 0.0001. This is clear from this study that spiritual belief consideration is very significant for speedy and complete improvement of psychiatric patients and it should be judicially applied in treatment protocol.

Acknowledgement

The authors would like to thank the staff and management of Pacific Institute of Medical Sciences, Udaipur (Raj.) for their whole hearted support in patient management and giving appropriate approvals.

How Stigma and Discrimination are Perceived by Rural or Urban Patients Suffering from Schizophrenia? An Exploratory Cross – Sectional Study from Western India

Bharat Agarwal[1], Sunil Kumar[2*] and G.K. Vankar[3]

[1]Assistant Professor; [2]Senior Resident, Department of Psychiatry, Ananta Institute of Medical Sciences and Research Centre, Rajsamand. [3]Department of Psychiatry, GFC Dutta Meghe Institute of Medical Sciences University, Vardha.

Original Article

ABSTRACT

Background: *Stigma is conceptualized as an attribute which is deeply discrediting and makes the person carrying it different from other and of a less desirable kind. Current study aimed to describe the nature and direction of experienced stigma; and discrimination reported by people with schizophrenia.* ***Methods:*** *One hundred and fifty patients diagnosed with Schizophrenia were selected from the Out Patient service of Psychiatry Department of a medical college general hospital. The experiences of stigma and discrimination were assessed using a semi-structured instrument developed by national working group for India by the world psychiatric association steering committee.* ***Results****: Differences were seen between rural and urban respondents. Patients from rural background more often reported these experiences: society treats differently, ridiculing by others, offensive comments, hiding from relatives, rejecting attitude of peoples around, attribution of supernatural cause as most common source of stigma, social exploitation, not fully accepted in the family, pushed into unacceptable social situation and sexual harassment. Reported narratives provided the direct view of these patients.* ***Conclusions****: Stigma experience is pervasive: it deeply affects the social, occupational and emotional wellbeing of patients with schizophrenia and should be included in clinical management. Effective anti-stigma intervention should target on improving attitudes and the condition for social integration in the community, empowering people with schizophrenia to challenge self-stigmatization and discrimination behavior towards them.*

INTRODUCTION

Schizophrenia is the most debilitating chronic psychiatric disorder which usually affects adolescents and young adults, disrupting pursuit of their educational and occupational goals. The disorder is associated with significant stigma and discrimination, which further increase the burden on these patients and their families. The essence of stigma is a negative and prejudicial attitude toward someone with a mental illness. Many people with mental illness describe the effect of stigma as severe, and more difficult to deal with as compared to the mental health problem itself. Discrimination occurs when people with mental illness are treated unfairly, or are denied their rights because of their mental illness. Individuals with schizophrenia often face social isolation; discrimination in housing, education and employment opportunities, and other forms of prejudice.[1]The stigma often extends to family members and to those who provide health care services to patients with the disorder. Major international studies suggest that schizophrenia has better prognosis in low-income nations and in rural settings.[2-4] The industrialization hypothesis has been advanced to explain this differential outcome which argues that industrial economies and attendant life styles lead to poor support, intolerance, rejection, isolation, segregation and institutionalization of the severely mentally ill.[5] The value placed on the autonomous individual in industrialized settings therefore accentuates social extrusion of the chronic mentally ill patient who assumes personal responsibility for the illness. In consequence, prognosis worsens in urban industrialized settings.

Studies on stigma and mental illness in the Indian setting have focused both on measurements of stigma and on locally important socio-cultural factors shaping stigma.[6-9] Numerous other studies have addressed public attitudes

towards mental illness.[10-12] The nature, determinants, and consequences of stigma vary across culture and region. Hence, there is a need for studies to understand the stigma specific to a particular region to plan intervention. Better understanding and identification of determinants may suggest ways to reduce stigma and help prevent its adverse consequences.

With this background, this study was aimed to study stigma and discrimination perceived by patients with schizophrenia and, its comparison between rural and urban patients.

METHODS

2.1 Material

This was a cross sectional study conducted at psychiatry OPD of Civil hospital Ahmedabad, Gujarat. Clearance from the institutional review board was taken prior to conducting the study. The sample consisted of one hundred fifty patients diagnosed with schizophrenia independently by two psychiatrists as per criteria laid down by diagnostic and statistical manual (DSM IV-TR). Information from the caregivers and the patient case file along with a mental status examination also were used for diagnostic confirmation. The purpose of the study was explained to patients and their caregivers. The consent of the caregiver was also taken. The patients' responses were recorded.

2.2 Inclusion criteria:

1. A patient with a diagnosis of schizophrenia under continuous remission of at least six-month period according to DSM IV-TR criteria.
2. Provision of the consent.

2.3 Exclusion criteria:

1. Those patients with co-morbid axis I /II disorder.
2. The patient having co-existing medical or substance use disorder other than nicotine.

2.4 Instruments for the study

A semi structured interview developed in an earlier study.[13] This instrument has been used on over 1000 patient in four cities, as a part of the Indian initiative of the world psychiatric program to reduce the stigma and discrimination because of schizophrenia. It consists of two parts: first part of the scale elicits the socio-demographic information of the respondents while second part of the scale measures stigma and discrimination experiences including nature of stigma experiences, attitude of relatives, friends and caregiver, source of stigma, consequences of stigma, patient's view how stigma could be reduced and to what level, comparison of severity of mental illness to other medical illness bringing disability. The verbatim regarding patient's stigma experience in areas like personal, family, social, occupational and in marital life also were recorded.

2.5 Statistical analysis

Both quantitative and qualitative analysis were done using computer. The data from urban and rural areas were compared to find out any difference. Quantitative data was analyzed by t-test and chi-square test. The narratives were read to identify the themes of stigma. For natural and objective analyses, the data were coded manually into constructs that emphasized stigmatizing experiences in various spheres of patient's life.

RESULTS

3.1 Socio-demographic characteristics:

The table 1 shows socio-demographic characters of the sample (N=150).

As shown in Table 1, majority of the patients were male (64%), Hindu by religion (86.6%), of age range 21-30 years (42%), married (49.3%), educated up to class 10th (69.3%), living in a joint family (52%), unemployed (62%), having income under 1000 rupees per month (68%).

Disease related characteristics: Seventy-nine (52.6%) patients (rural=18, urban=61) were having paranoid subtype of the disorder. One hundred thirty-six (90.6%) patients (rural=36 and urban=100) were having duration of illness more than two years.

Table: 1 Demographic characteristic

S. No.	Sample (N=150)	Rural N=39 (26%)	Urban N=111 (74%)
1.	**Religion**		
	Hindu (130, 86.6%)	33 (84.6%)	96 (86.5%)
	Muslim (17, 11.3%)	05 (12.8%)	12 (10.8%)
	Others (3, 2%)	01 (2.5%)	03 (2.7%)
2.	**Gender**		
	Male (96, 64%)	23 (59%)	73 (65.8%)
	Female (54, 36%)	16 (41%)	38 (34.2%)
3.	**Age (years)**		
	21-30 (63, 42%)	20 (51.2%)	39 (35.1%)
	31-40(42, 28%)	08 (20.5%)	34 (30.6%)
	41-50 (28, 18.6%)	09 (23.0%)	19 (17.2%)
	>50 (17, 11.3%)	02 (5.1%)	15 (13.5%)
4.	**Marital status**		
	Married (74, 49.3%)	18 (46.1%)	56 (50.4%)
	Unmarried (39, 26%)	09 (23.1%)	30 (27.0%)
	Divorced (19, 12.6%)	03 (7.7%)	16 (14.4%)
	Other (18, 12%)	09 (23.1%)	09 (8.1%)
5.	**Education**		
	Illiterate (18, 12%)	06 (15.4%)	12 (10.8%)
	Up to class X (104, 69.3%)	24 (61.5%)	80 (72.1%)
	Higher (28, 18.6%)	09 (23.0%)	19 (17.2%)
6.	**Family type**		
	Nuclear (68, 45.3%)	14 (35.89%)	54 (48.6%)
	Joint (78, 52%)	24 (61.5%)	54 (48.6%)
	Other (4, 2.6%)	01 (2.5%)	03 (2.7%)
7.	**Employment**		
	Employed (57, 38%)	08 (20.5%)	49 (44.1%)
	Unemployed (93, 62%)	31 (79.5%)	62 (55.8%)
8.	**Income (rupees per month)**		
	<1000 (102, 68%)	31 (79.5%)	71 (64%)
	>1000 (48, 32%)	08 (20.5%)	40 (36.0%)

Table 2 shows various stigma variables experienced by the patients.

Table 2: Common stigma experienced by patients

Variable	Rural N, (%)	Urban N, (%)	Chi square
Society treats differently	27(69.2%)	60 (54.0%)	X^2=2.73, df=1, p=0.09
Ridiculing by others	29(74.4)	67(60.4)	X^2=2.45, df=1, p=0.11
Offensive comments	30(76.9)	62(55.9)	X^2=5.40, df=1, p=0.02
Hide from relatives	26(56.7)	57(51.3)	X^2=2.74, df=1, p=0.09
Difficulty in getting marriage proposal	09(23.1)	36(32.4)	X^2=1.20, df=1, p=0.27

Table 3 shows various consequences of the stigma and discrimination experienced by the patients. Other findings of the study were as mentioned here. The most common reported source of stigma was attribution of supernatural cause in rural patients (41%) while in urban patients it was

not being able to work due to illness (39.6%). Avoidance was the most common attitude of relatives towards patients in both regions (51.2% rural, 41.4% urban).

Table 3: Consequences of the stigma and discrimination

Variable	Rural N, (%)	Urban N, (%)	Chi square
Avoid disclosing the mental illness histories in jobs/application	03 (7.69%)	21 (18.92%)	X^2=2.71, df=1, p =0.100
Social exploitation	25 (64.10%)	40(36.04%)	X^2=9.26, df=1, p=0.002
Not fully accepted in the family	29 (74.36%)	61 (54.95%)	X^2=4.53, DF=1, p=0.03
Pushed into unacceptable social situation	11 (28.2%)	15 (13.5%)	X^2=4.35, DF=1, p=0.04
Sexual harassment	14 (35.9%)	20 (18.0%)	X^2=5.26, DF=1, p=0.02
Living alone	24 (61.5%)	80 (72.1%)	X^2=1.5, DF=1, p=0.22

Friends and relative either stopped visiting at all or visited less frequently in rural patients (43.5%), while 42.3% urban patients reported that friends and relatives stopped visiting at all. In rural area, patients attributed their illness to faulty biological functioning (33.3%) while in urban area patients accepted that they are mentally ill (45.0%). Mental illness was reported as most disabling illness by 71.7% rural and 54.0% urban patients. Forty one percent rural patients while 34.2% urban patients reported that stigma can be partially cured. Involvement in advocacy activities was reported to be an effective strategy to reduce stigma by 64.2% rural and 55.8% urban patients. Most of the patients (94.8% rural and 77.4% urban) reported that concealing or selective disclosure of the illness is not an effective strategy to reduce stigma. Increasing awareness of the mental illnesses was reported to be an effective way to reduce stigma (69.2% rural, 65.7% urban).

Common stigmatizing verbatim reported by the patients:

I. Common stigmatizing verbatim reported by rural patients:

- "In the society, nobody enquires about me. Nobody loves me. Nobody even looks at me. They call me 'mad', and laugh at me. They don't even invite me at their home on festivals. Due to my illness, my marriage is not getting fixed."

-"In my village when houses were repaired, everybody got the letter but they didn't provide the same for met. Nobody wants to come and meet me. Today I have a broken house to stay pending repair work. I asked for help from my friends and relatives but nobody comes forward. Every times during rain, water comes into my house no body helps me."

II. Common stigmatizing verbatim reported by urban patients:

- "When I fell ill, everyone in my house kept nagging me all day. They didn't give me food. They used to beat me and threw me out of house, when I went to my mother's place, there also people used to nag me. In the beginning, my husband was cooperative, but now he doesn't talk to me much and does not maintain sexual relationship with me."

- "Neighbors don't talk to me. When I go to collect water in the morning, they keep on pushing me, they throw my vessels away. They abuse me and also hit me. My house owner keeps on telling me and my family members to vacant the house."

Consequences of Stigma

I. Experiences related to personal area:

- "I was bright in study prior to the illness, but I quitted my study as I failed in 10th. My memory power went down. My writing is also getting bad. I can't work at my home as I get tremor at my hand. I am unmarried yet, few relative come for my younger sister but when they knew about my illness, they went away."

II. Experiences related to Occupational area:

- "At my work place, people call me "mad". My boss gets angry on me every day and says that my head is empty. He always says me that they will sack me. At lunch hour I am not allowed to have lunch while everybody else is going for lunch. I get half the salary others get."

III. Experiences of stigma and discrimination in Social life:

- "I have one house with 2 BHK in Ahmedabad. When some relatives come to the city, though they stay at my house but nobody of them takes lunch or drinks water at my house. They stay only up to next morning and leave afterwards. Neighbors don't talk to me. They said me that I am mad. They give me work always without giving me any money, and upon asking, they refuse for the money."

- "Before illness, I was living in rented house. I was an inspector in IT department. People used to meet me and respect me, but when owner of the house knew about my illness, he asked me to vacate his house. Today I am living in small house alone. People avoid me."

IV. Experiences related to marital life:

- "Because of illness I am not able to work in my land. My land remains uncultivated. My desire for sex has come to an end. My penis is not erectile any more. Due to this, my wife left me and went to her parents place. Today she has got married to another person."

- "I was married in great pomp. My mental illness started at my in laws place. Initially they used to beat me a lot, they took me to a faith healer, after that they left me to my mother's place. My mother tried for many attempts one after another for my marriage. Every time, as my wife knew about my illness, she divorced me."

V. Experiences of stigma and discrimination in Family:

- "I had to hide my illness because mine and my sister's marriage were at stake. I got married in far Village, but when knew about my illness, they sent back me to my maternal home. I was pregnant at that time. After delivery, they called me back but when I was breast feeding my baby, my mother in law took my baby away and told, "You are mental and the child will also become mental if you breast feed the baby."

- "Nobody takes care of me at home even if I am ill and I need medication regarding this. When I told my brother and father about this, so they became angry on me and said you are mad, go wherever you want to, we do not have time for you"

VI. Impact of illness on General Life

a. Hiding of illness:

- "I have to stay in my house all day hiding my illness. Whenever I come at the window, my mother gets angry on me and directs me to go inside. She tells me that if people will know about my illness then nobody will marry me and my sister."

b. Decrease in Work efficiency and cognitive function:

- "Welding was my profession earlier but today I cannot concentrate on my work properly. I have been injured also because of this."

c. Visiting of Friends and Relative:

- "Since the starting of my illness, people are scared of me and they don't come near me. I had to live alone at home."

d. People's reaction after knowing their illness:

- "If any one comes from my family, they talk only one thing, to take medicine but nobody talks to me more than this. I have to live alone."

e. Most Disabling Illness:

- "Mental health problems should not occur. It becomes difficult to work. I am feeling better till I take medicine but my memory is decreasing. Nothing is remembered. I have to take pills to sleep in night."

DISCUSSION

The present study was aimed to study stigma and discrimination perceived by patients with schizophrenia and, its comparison between rural and urban patients. Majority of the patients were male, Hindu by religion, of age range 21-30 years, married, educated up to class 10th, living in a joint family, unemployed, having income under 1000 rupees per month. Findings of present study revealed that patients from rural background had more often stigmatizing and discriminating experiences compared to patients from urban background.

In our study, 62% patients were unemployed. Due to unemployment and chronic nature of illness, patients are not able to do their work as efficient as of their same age group in the society, which becomes the main culprit associated to creation of stigma. Stigmatization in the workplace and the related denial of access to job are the most important experiences of social exclusion. These experiences are recognized as the main factors producing and maintaining a high rate of unemployment among those with schizophrenia. In our study too, 21 (18.9%) urban and 3 (7.6%) rural patients reported avoiding disclosure of mental illness histories in job/applications.

In the present study, patients from rural background more often reported these experiences: society treats differently (p=0.09), ridiculing by others (p=0.11), offensive comments (p=0.02), hiding from relatives (p=0.09). Jadhav S et al also reported that rural Indians show significantly higher stigma scores.[14] Similar to our study an Indian study by Loganathan S et al reported that rural respondents experience more ridicule, shame, and discrimination but they reported that urban respondents feel the need to hide their illness.[15] Fear of rejection may be a need to hide their illness from others particularly in rural areas. In our study, more urban patients reported difficulty in getting married compared to rural patients (p=0.1). Weiss et al,[16] studying psychiatric stigma across cultures, pointed out that "in Bangalore the main concerns the sample had, were related to lowering their own chance of entering a good marriage and decreasing the chance of one of their relatives". Disclosing the diagnosis of schizophrenia becomes stigmatizing due to fear of being ridiculed, discriminated, leading to loss of job or not being able to get a job, and difficulty in getting married for the patient as well as family members. So, family members handle with it by hiding the diagnosis or not disclosing the presence of illness.

In our study, more rural patients reported social exploitation (p=0.002), not fully accepted in the family (p=0.03), pushed into unacceptable social situation (p=0.04), and sexual harassment (p=0.02) as a consequence of stigma and discrimination compared to urban patients. Jadhav et al also found that rural Indians showed a more stigmatizing attitude towards severe mental illness. Their study also showed greater stigma and a punitive attitude amongst rural Indians as compared to urban Indians.

In our study, rural patients reported attribution of supernatural cause as the most common source of stigma. Studies support this finding that in rural areas, the frequent association of mental illness with malevolent spiritual forces induces many families with a member with mental illness to seek help from shamans.[17,18] In rural areas, lack of adequate education regarding mental illnesses leads to such beliefs. Jadhav et al also concluded that urban Indians have a more liberal and tolerant attitude but were also more excluding of those with mental illness at work.[14] In our study too, not being able to work due to illness was the most common reported source of stigma in urban patients (39.6%).

In our study, rural patients reported rejecting attitude of peoples around while urban patients reported nagging and uncooperative attitude of the family members and society. Stigma led to painful experiences related to patient's personal and occupational area, social life, marital and family life. Fact of hiding the diagnosis of schizophrenia was also reported by the patients. Resulted decrease in cognitive functioning and impaired work efficiency also was reported by the subjects. The extent of the discrimination due to the illness resulted in stopped or less frequent visiting of the friends and relatives to the patients. The people around made either limited or no communication with the patients. Patients reported schizophrenia as the most disabling illness of all the illnesses.

Lack of correct knowledge is the variable associated with more stigma responses. Setting up programs directed towards modifying the attitudes of employers, as well as greater attention to the employment-related training of social workers could constitute useful instruments to improve labor market access for people with schizophrenia. These programs should help convincing employers that people with schizophrenia are highly motivated and can provide important contributions. At the same time, people with schizophrenia might need specific support in re-entering the labor market, such as Individual Placement and Support (ISP) Programs [19, 20]. Better integration in the labor market has been shown to improve clinical outcome[21-23] and reduce the risk of hospitalization.[24]

Stigma and negative public attitudes for a patient with schizophrenia is widely prevalent both in rural as well as urban areas. Therefore, while patients continue to consider stigma as a central obstacle to their integration into the community, they themselves contribute to this process by accepting public stereotypes as applicable to themselves. As a result, majority of them don't confront negative reaction, and lose self-esteem, isolate themselves and get worse. Our data from patient verbatim also highlighted that patient focus on the stigmatization experiences and on their ideas of the cause of stigma; while hardly offering any suggestions for anti-stigma intervention. Suggestion of participant mainly concerned the improvement of information on mental health issues among the public (66.7%). Participant did not seem to envisage many opportunities for positive change and found it difficult to formulate specific proposal on what could be done to improve their situation. Sorting out this difficulty might help reducing perceived stigma, discrimination and their consequences. Spending more time with a patient, may reduce stigmatizing and discriminating attitude presumably through the mechanism of exposure induced reduction of negative stereotype about the mental illness. Alexander & Link concluded that increasing personal contact with psychiatric patient could reduce people's stigmatizing

attitudes.[25] Couture & Penn also concluded that both retrospective and prospective contact tends to reduce stigmatizing views of persons with a mental illness.[26] Our findings suggest that people with schizophrenia are not fully accepted in the family, especially in rural areas. This suggests that certain factor could be more powerful than negative stereotypes in interpersonal stigmatization which can be overcome by provision of the scientific knowledge of the mental illnesses and re-integration of the patient in the community through psychosocial approaches.

Similar to our findings, Chinese families too, frequently concealed the mental illness of their members.[27] Family members act as both stigmatizer as well as victim of stigmatization themselves.[28] Because of this paradoxical role dualism, family members might project their anger towards a patient for causing them added suffering. This negative affective state, we suspect, could heighten the chronic burden of care. Providing adequate non-pharmacological measures may help family members in such circumstances of negative affective state. Provision of psychiatric care must move beyond symptoms control to diminish intentional as well as subtle forms of stigmatization in the patients' social life. Effective anti-stigma intervention should target on improving attitudes and the condition for social integration in the community, empowering people with schizophrenia to challenge self-stigmatization and discrimination behavior towards them. Regarding the work-related stigma, we believe that a combination of corporate education programme, legal measures and advocacy efforts are needed.

CONCLUSION

Stigma experience is pervasive: it deeply affects the social, occupational and emotional wellbeing of patients with schizophrenia and should be included in clinical management. Higher level of stigma is related to low education level, unemployment status. The provision of accurate information through trusted community sources and open dialogue may help to dispel myths, correct faulty assumption and increase the involvement of participation of community in dragging out the root source of stigma. Family programmes should be started early in an attempt to reduce stigma from significant others and to transform the family into a long recourse for psychiatric rehabilitation. Effective anti-stigma intervention should address chiefly two targets: improving attitudes and condition for social integration in the community and; empowering patients with schizophrenia to challenge self-stigmatization and discriminatory behavior towards them.

Gender differences and suicide intent among patients with depression

Dr. Siddharth Aswal[1], Dr. Vinod Kumar Aswal[2], Dr. Aviral Verma[3*]

Abstract
Suicide is a word that many people like to avoid. Talking about suicide makes most people cringe and makes them very uncomfortable. Suicide affects teenagers and young adults around the globe each year. There are well-documented gender differences in adolescent suicidal behavior; death by suicide is more common in males, while nonfatal suicide attempts are more common among females. Over the past three decades, researchers have documented the effectiveness of a myriad of suicide prevention initiatives. However, there has been insufficient attention to which types of suicide prevention interventions are effective in changing attitudes and behaviors for young males and females. The aim of the study was to assess the level of Suicide Ideation among male and female patients of depression. The sample of 70 patients suffering from depression were selected from the OPD and IPD of Department of Psychiatry, Pacific Institute of Medical Sciences (PIMS), Udaipur on the availability basis. Beck Scale for Suicide Ideation (BSS) was administered on the male and female patients suffering from depression. The scoring of the tests was done according to the manual. Results showed that female patients suffering from depression were found to perceive more suicidal ideation and intent as compared to the male patients suffering from depression. It was concluded that intervention strategies must be prepared for the depressive disorder patients along with the other treatment strategies.

Keywords: male, female, depression patients, suicide ideation

Introduction
Suicide is a leading cause of death and a significant mental health problem worldwide [1, 2]. Suicide is defined as death caused by self-directed injurious behavior with any intent to die as a result of the behavior [3]. Adolescence is a period of marked risk for suicidality [1]. For youth between the ages of 10 and 24, suicide is the third leading cause of death, significantly superseding the rate for adults aged 35 to 54 [4]. Males are more likely to die as a result of suicide: the male-to-female ratio of death by suicide is four to one in the U.S. [1, 2, 4].

Suicide attempt is defined as a non-fatal self-directed potentially injurious behavior with any intent to die as a result of the behavior; a suicide attempt may or may not result in injury [3]. In almost all regions of the world, nonlethal suicide attempts are more common in females [2]. Males are more likely to use more lethal means than females, partially accounting for the different pattern for suicidedeaths and attempts [1, 5]. Gender differences also exist in attitudes about suicide with males tending topossess more maladaptive attitudes about suicide than females [6]. These patterns are evident across development from adolescents to elderly adults [1, 7], yet are generally more robust among individuals 15 to 29 years of age [2].

Taking into consideration such robust gender differences, one might expect that validated approaches to suicide prevention would also commonly consider gender differences when planning and evaluating the effects of interventions. Unfortunately, there has been insufficient attention to individual differences in risk for suicidality and intervention response [8]. Prominent reviews of suicide prevention literature have rarely focused on the role of gender [5, 9]. Recently, this oversight has been identified by Klimes-Dougan, Klingbeil, and Meller [10], who called for further inquiry into the issue of gender differences in suicide prevention programming.

Review of literature
Perhaps the strongest evidence of gender differences in response to curricula was reported in the work of Shaffer *et al.* [11]. A pretest-posttest design was used to evaluate a suicide prevention program in four high schools. The program consisted of a mixture of teacher instruction and discussion. Few positive effects of the program were found. Having participated in the intervention, male suicide attempters were significantly more likely to feel that the program "will make it harder to deal with my friends' problems," and were significantly more likely to "know someone who was upset a lot by the program." More males than females who had attempted suicide and more male non-attempters found the programs boring. Attempters exposed to the program were less likely to recommend the presentation of the program to other students and were more likely to agree that talking about suicide "makes some kids more likely to try to kill themselves." These results were highly controversial, leading some to question the utility of curriculum programs.

Within a college student sample, Garlow*et al.* [12] assessed the results of the American Foundation for Suicide Prevention College Screening Project at Emory University. A nine-item depression module measured suicidal ideation, past suicidal attempts, episodes of deliberate self-harm, and

symptoms of distress. Although more females (n = 519) than males (n = 205) volunteered to participate in this study, a larger proportion of male respondents (14.6%) were willing to report suicidal ideation than females (9.83%). The authors hypothesized that the emphasis of depression in the screen may have caused the female-rich sample and suggested that an emphasis on anger or stress may have been more successful in attracting male participants [12].

A study by Miller, Coombs, Leeper, and Barton [13] compared several central city counties in the United States in a) suicide mortality rates, and b) presence and frequency of suicide prevention centers, crisis centers, and mental health facilities. Using data from the National Center for Health Statistics, the authors focused on regions that had recently initiated prevention centers *versus* counties in which the number of centers remained the same. They found that the implementation of suicide prevention centers favorably impacted and minimized suicide rates in white females younger than twenty-four years of age, the most frequent callers to crisis centers. Counties in which the number of centers remained stagnant housed increased mortality rates for both males and females [13].

Methodology

Objectives

The objective of the present research work was to assess the level of Suicide Ideation among male and female patients of depression.

Hypothesis

There will be a significant difference between the level of Suicide Ideation among male and female patients of depression.

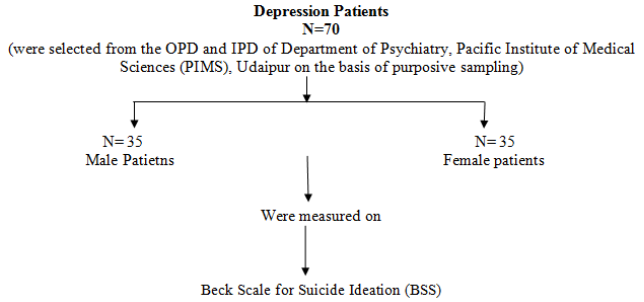
Variables

- Male patients of depression
- Female patients of depression
- Suicide Ideation

Sample

The sample of 70 patients suffering from depression were selected from the OPD and IPD of Department of Psychiatry, Pacific Institute of Medical Sciences (PIMS), Udaipur on the availability basis. The sampling technique used was purposive sampling and the sample was randomly selected as per the inclusion criteria.

Research Plan



Inclusion Criteria

The sample was further limited to -

1. Patients of the age range of 20-40 years were taken.
2. Patients with 1- 3 years of duration of illness were included.
3. The locale of the study was Udaipur city of the State of Rajasthan.
4. Informed consent.

Exclusion criteria

1. Patients having the treatment history of less than 1 month.
2. Uncooperative patients were excluded.
3. Patients having any other comorbid mental or physical illness were excluded.

Tools Employed

- Beck Scale for Suicide Ideation (BSS) [14]

Procedure

After deciding the research plan, design and sample, rapport was established amongst the patients. Tests were administered on the male and female patients on the basis of the study. Beck Scale for Suicide Ideation (BSS) was administered on the male and female patients suffering from depression. The scoring of the tests was done according to the manual. Results and interpretations were carried out according to the data obtained after statistical analysis.

Controls

1. In order to manage the bias due to order of the items of the scale, the scale was administered in the random order.
2. To control the extraneous variables all, the testing work was done by the investigator himself.
3. The confidentiality of the results was assured.

Statistical Analysis

For analyzing the data for assessing the suicide ideation of male and female patients suffering from depression, Frequency, Percentage and other descriptive statistics were used.

Results and Discussion

The purpose of the study was to assess the level of suicide ideation among male and female patients of depression. The sample of 70 patients suffering from depression were selected from the OPD and IPD of Department of Psychiatry, Pacific Institute of Medical Sciences (PIMS), Udaipur on the availability basis. The sampling technique used was purposive sampling and the sample was randomly selected as per the inclusion criteria. The Becks Suicide Ideation Scale was administered over these patients to basically assess the impact of depression and gender on the frequency of the occurrence of suicidal thoughts. The results obtained were tabulated and the interpretation was drawn as follows-

Table 1 highlights the number of respondents taken into the study, it may be seen that total 70 patients were selected from the IPD and OPD where 35 were female and 35 were male. When male patients were taken into account, 20 male patients and 20 female patients were included under the age group of between 20-30 years and 15male patients and 15 female patients were in the age groups of 30-40 years. When the duration of illness was considered, out of the 35 male and 35 female patients suffering from depression, 10 male and female patients out of them were having the duration of illness of 1-2 years whereas 25 of the male and female

patients suffering from depression were between the duration of illness of 2-3 years.

After the administration of BSS, the results were quite significant. The data was tabulated in table 2 where it may be clearly observed that patients perceive a great deal of problems and feel sad, hopeless and worthless. This pressure overpowers their mind to a lot of extent which makes them feel like nothing can support them, they have no future and the only was left now is to quit.

Table 1: Showing sample distribution of patients suffering from depression.

S. No.	Category	Gender				Total
		Male (N=35)		Female (N=35)		
		Freq	%	Freq	%	
1.	Age (20-. yrs)	20	28.5%	20	28.5%	40
2.	Age (30-40 yrs)	15	21.4%	15	21.4%	30
3.	DOI (1-2yr)	10	14.2%	10	14.2%	20
4.	DOI (2-3yr)	25	35.7%	25	35.7%	50

Table 2: Indicating percentage of depressive patients suffering from high, medium and low level of suicide intent.

Class	BSIS		
	Category	Frequency	Percentage
Male	High	9	25.7%
	MEDIUM	15	42.8%
	LOW	11	31.4%
	Category	Frequency	Percentage
Female	HIGH	14	40%
	MEDIUM	12	34.2%
	LOW	9	25.7%

As seen from the table, majority of the male patients perceived medium (42.8%) and low (31.4%) level of suicide ideation. It was seen that 25.7% of the male depression patients had high level of suicide ideation. The results indicated that male patients suffering from depression do perceive suicide ideation.

When level of suicide ideation of female patients suffering from depression was examined, it was found that 40% had high and 34.2% perceived medium level of suicide ideation. Only 25.7% of the female patients were seem to have low level of perception towards suicide intent. The Results clearly indicate that 68.5% of the total male patients perceived suicidal thoughts during depression and 74.2% of the female patients suffering from depression were found to have high and medium level of suicide ideation in their lives. The data obtained do indicate that female patients perceive more suicidal thoughts in comparison to male patients. More female patients were seeming to have high level of suicide ideation as compared to male patients.

Similar study was conducted by Li *et al*., (2019) [15] where it was found that Major depressive disorder (MDD) is associated with high risk of suicide. Conventional neuroimaging works showed abnormalities of static brain activity and connectivity in MDD with suicidal ideation (SI). However, little is known regarding alterations of brain dynamics. More broadly, it remains unclear whether temporal dynamics of the brain activity could predict the prognosis of SI. The study suggested that alterations of temporal variability in regions involved in executive and emotional processing are associated with SI in MDD patients. This novel predictive model using the dynamics of intrinsic brain activity could be useful in developing neuromarkers for clinical applications [15].

Thus, it may be said that along with the treatment for depression, the patients should also be given some intervention to reduce the occurrence of suicidal thoughts among the patients. proper counselling, guidance and treatment for both depression and eliminating any self-harm behavior may be given to the patients to decrease the incident of suicide.

Conclusions

It may be concluded by the results obtained that people in the India, are facing a lot of pressure from their external surroundings for performing well. This pressure is becoming one of the major factors in discouraging the person and increasing hopelessness which leads to increase in the level of suicide intent. Thus, major steps should be taken against changing the perception of the public.

Implications

Based on the above discussion, many strategies and directions may be advised for future researches in this area such as: -

1. Further studies are needed with larger sample size and deeper evaluation to generalize the result.
2. Some other variables may be included to achieve better information on the topic.
3. Further interventions and follow ups may be given to such students and feedback may be taken.
4. Training may be provided to these students on the certain technique of stress management and medication which insure longevity and would enhance quality of life.
5. Counseling strategies may be offered for enhancing physical, mental, emotional and cognitive state of these patients.

Abstract

Recent literature considers duration of illness (DI) and duration of untreatedillness (DUI) as important factors influencing outcome in many psychiatric conditions. The aimof the present article is to analyze the relationship between DI and DUI, and pharmacologicalresponse in the different psychiatric disorders with particular emphasis on neurodegenerativeaspects. An updated review of the current literature was conducted through PubMed in orderto compare different studies focused on DI and DUI, and treatment response in major psychosesand in depressive/anxiety disorders. A significant body of evidence shows that a prolongedDI and DUI is associated with brain abnormalities and poor treatment response, particularly inschizophrenia. Nevertheless, an increasing number of studies point toward a similar conclusionin mood and anxiety disorders as well, even though fewer studies have been published in thisfield. The present study was undertaken to assess and compare the disability in patients with obsessive compulsive disorder (OCD) using Indian Disability Evaluation Assessment Scale (IDEAS). Results indicated Significant disabilityin work and global score was seen in patients of obsessive-compulsive disorder with duration of illness >5 yr. it was concluded that these illnesses affect all areas of daily functioning leading to greaterdisability, and thus increasing the burden on the family, pose greater challenge for therehabilitation of patients and their inclusion in the mainstream of the family and society. Furtherstudies on a larger sample need to be done to confirm the finding.

Keywords: obsessive-compulsive disorder, Indian Disability Evaluation Assessment Scale, duration of illness, disability.

Introduction

Disability associated with psychiatric disorders is considered an important public health problem in developing countries like India [1]. Disability due to psychiatric illness refers to dysfunction or inadequate performance in specific activities of daily living which are normally expected from a person according to his age, sex and societal role [2].

About one-third of patients having Major Depressive Disorder (MDD) and Bipolar Affective Disorder (BPAD) have a severe disability. Self-care and work were the dysfunctional areas in MDD while BPAD affected all areas of functioning [3,4].

Non-psychotic disorders such as OCD also run a chronic course and can cause disability. It is reported that about 16-17% OCD and anxiety disorders result in significant disability [3]. However, Olfson et al., did not observe any significant disability in OCD [5]. OCD is the only non-psychotic illness for which the government of India sanctions disability benefits. Effective treatment and the issue of monetary benefit for the disabled by the government assume importance

in this context. In this background, it is important to assess the extent of disability in OCD.

Obsessive Compulsive Disorder (OCD) is characterized by recurrent obsessions or compulsions that are severe enough to be time-consuming or cause marked distress or significant impairment and is given disability benefits as per the existing Indian disability act.

Psychiatric disorders are one of the most common and prevalent illnesses that widely affect world population accounting for nearly 31 per cent of world's disability. Five of the 10 leading causes of disability worldwide are in the category of mental disorders: major depression, alcohol use, bipolar affective disorder, schizophrenia and obsessive-compulsive disorder[6]. Psychiatric illnesses like schizophrenia, bipolar affective disorder and obsessive-compulsive disorder, impact negatively on the academic, occupational, social and family functioning of the patients.

It has been demonstrated that in the patients of mood and anxiety disorders, residual disability and poor quality of life continue even after completion of symptom-linked treatment[7,8]. There is amelioration of symptoms with pharmacotherapy, but social functioning and quality of life improve only with concerted efforts at rehabilitation that take longer intervals of time[9].

There is limited available literature which assessed disability among non-psychotic illnesses in Indian setup. However, there are some community-based studies to assess mental disability in mental disorders [10]. Hence, the present study was planned to assess disability in OCD.

Methodology

Patients attending outpatient section of Department of Psychiatry, Pacific Institute of Medical Sciences, Udaipur, Rajasthan, India, were screened to include in this cross-sectional study. Those diagnosedto be suffering from schizophrenia and obsessive compulsive disorder by ICD-10 DCR [11], with duration of illness of minimum two years without any exacerbation or hospitalization, and accompanied with a primary care giver were assessed further.All patients with co-morbid medical andpsychiatric illness, likely to contribute in disability,were excluded. Informed consent was taken from theprimary care giver. The target was to include about 30 consecutive patients for each illness. IDEAS wasapplied in all the patients who fulfilled the selection criteria to measure the disability.

A total of 27 patients of (27 with obsessive-compulsive disorder) wereincluded in this study. Of the 30 patients of obsessive compulsive disorder initially included, 3 patients were excluded as they were found to have conditions likely to cause disability per se (one had a seizure disorder, another had a history of intermittent excessive alcohol abuse, and the third one developed severe anxiety symptoms).

Results and Discussion

Many patients with OCD were from urban background in our study. The poor representation of rural population may be due to the inability to understand this being an illness. It has been shown that obsessive-compulsive disorder produces a significant impact on daily living. [12,13]

Table 1: Socio-demographic characteristics of patients with obsessive-compulsive disorder

Category	Sub-divisions	OCD No.	Percentage (Round off)
Age groups	16-30	14	52
	31-45	11	41
	46-50	2	7
Gender	Male	15	56
	Female	12	44
Domicile	Urban	18	67
	Rural	9	33
Religion	Hindu	21	78
	Muslim	6	22

Table 2: Assessment on various items of IDEAS in patients of obsessive-compulsive disorder between duration of illness 2-5 yr and >5 yr

Duration of illness	Self-care	Interpersonal Activities	Communication and Understanding	Work	Global Disability score
2-5 years (N=8)	0.2 ± 0.1	0.63 ± 0.52	0.75 ± 0.89	0.50 ± 0.53	3.13 ± 0.83
>5 years (N=19)	0.58 ± 0.96	1.16 ± 0.9	1.52 ± 1.02	1.79 ± 1.18*	7.95 ± 3.34**

Values are mean ± SD

P *<0.01, **<0.001 compared to those with OCD (2-5 year duration)

In our study, there was more work impairment in patients with OCD with duration of illness more than 5 years than in patients with duration of illness between 2-5 year; this however, needs confirmation in a larger sample. The factors responsible for deterioration inthe working ability of patients with obsessive compulsive disorder need to be explored in further studies. The disability produced in areas of self-care, interpersonal activities and communication and understanding remained stable over the time. Koran et. al[14]reported that 22 per cent of OCD patients were unemployed, however, Khanna et. al [15]did not substantiate the same findings. Notably these twostudies did not include the patients with duration ofillness more than 2 yr.

Other workers [17,18]also reported that patients with OCD had greater disruption on their careers and relationships with family and friends. However, in these studies [16-18], no attempt was made to match the patients on the basis of duration of illness.

It appears that the instrument IDEAS is sensitive enough to pick up disability even at mild severity of illness. However, results of our study should be interpreted with caution. This was a cross-sectional small sample study, based on exclusively hospital-based outpatient sample, and therefore, is not likely to be representative sample of patients in community. Moreover, the premorbid assessment using standardized instruments was not carried out. The relationship between disability and socio-demographic variables like family structure, family income etc., needs to be evaluated in further studies.

ABSTRACT

Background: Magnetic Resonance Imaging (MRI) is the most commonly used imaging modality in the evaluation of knee injuries. So, this study was planned to use MRI in determining the incidence of knee lesions in traumatic knee patients and their relation with the age and sex of the patients.
Materials and Methods: This prospective study was performed for a period of 1 year after taking the permission from institutional ethics committee in a tertiary care teaching hospital. Patients referred to the Department of Radiology with post traumatic knee joint symptoms were recruited. Patients' socio-demographic data, clinical history and physical examination findings were recorded to correlate the findings. MRI Acquisition Knees were imaged by using Siemens Avanto MR machine with a superconducting magnet and field strength of 1.5 tesla using dedicated knee coil (Flex).
Results: Total 63 patients were examined by MRI and the most common age group was found to be 21-30 years. 88.89% knee lesions were found in male. Joint Effusion was found to be most frequent lesion in symptomatic knee constituting 94.64%. Amongst the ligament injury, ACL was found be highest approximately 50% in patients with complete tear in 57.14%. Amongst the menisci injury medial meniscus injury was found be highest approximately 72.72 % with grade III in 43.75%.
Conclusion: MRI was found to be good diagnostic tool for evaluation of traumatic knee lesions.

INTRODUCTION

The knee joint is the largest and most heavily loaded joint of the human body (Potocnik *et al.*, 2008). In the knee joint, the bones, cartilage, menisci, joint capsule, ligaments, muscles, and tendons interact in a unique manner, providing both stability and mobility (Brantigan and Voshell, 1941). The knee is one of the most frequently injured joints and at the time of injury to knee joint these structures are vulnerable to be affected, some are easily and frequently affected during injury and some are rarely (Beynnon, 1998; Ryder *et al.*, 1997). Different techniques have provided a tremendous amount of information about degeneration, prevention and treatment of disorders and injuries in the knee. (Potocnik *et al.*, 2008; Pena *et al.*, 2006)

**Corresponding author: Dr. Ritu Mehta,*
Department of Radiodiagnosis, Geetanjali Medical College and Hospital, Udaipur, Rajasthan, India.

Compared to arthroscopy, which is considered the reference standard, the sensitivity and specificity of MR images are high for detecting abnormalities in knee joints (Oei *et al.*, 2003; Vincken *et al.*, 2002). So, MRI is the most commonly used imaging modality in the evaluation of the knee joint, and has an acceptable accuracy in the detection of menisci and anterior cruciate ligament (ACL) injury (Crues *et al.*, 1987). MRI produces excellent pictures of articular cartilage, synovium and bone marrow that might be expected to produce information that correlates better with the patient experience of symptoms and guides treatment planning. From all knee soft tissue structures, the ligaments and joint capsule are the most frequently injured structures (Beynnon, 1998). Knee pain and related symptoms may come as a result of damage to one or more of the soft tissue structures that stabilize and cushion the knee joint. Post traumatic knee complaints are the most common reason for patients to come in hospital. Traumatic knee complaints can be caused by e.g. bone bruise, fracture,

and/or soft tissue injuries such as lesions of menisci, cruciate ligaments, collateral ligaments and muscles (Oei *et al.*, 2003; Belo *et al.*, 2010). MRI showed a sensitivity of 86%, 91%, 76%, a specificity of 95%, 81%, 93% and an accuracy of 93%, 86%, 89% for anterior cruciate ligament, medial and lateral meniscus lesions respectively (Crawford *et al.*, 2007). There are no data available on prevalence of such lesions in our institute and also this type of study was not conducted in this region of Rajasthan. So, this study was planned to determine the incidence of common knee lesions in symptomatic knee injury patients by using MRI.

MATERIALS AND METHODS

This prospective study was carried out for a period of 1 year after taking the permission from institutional ethics committee. A total of 63 patients referred to the Department of Radiology with post traumatic knee joint symptoms were recruited. Informed consent was obtained after explaining about the nature of exam and also the socio-demographic data, clinical history and physical examination findings were recorded to correlate the findings. Patients who had no clinical evidence of knee joint involvement were not included in this study.

Procedure

MRI Acquisition Knees were imaged by using Siemens Avanto MR machine with a superconducting magnet and field strength of 1.5 tesla using dedicated knee coil (Flex). Each examination consisted of the following: coronal intermediate-weighted (repetition time msec/echo time msec, 2200/20) and T2- weighted (2200/80) dual spin-echo images (number of signals acquired, two; section thickness, 5 mm; intersection gap, 0.5 mm; field of view, 160 mm; acquisition matrix, 205×256; and number of sections, 18), sagittal intermediate-weighted (2200/20) and T2- weighted 4 (2200/80) dual spin-echo images (number of signals acquired, two; section thickness, 4 mm; intersection gap, 0.4 mm; field of view, 160 mm; acquisition matrix, 205×256; and number of sections, 20), sagittal three dimensional T1- weighted spoiled gradient-echo frequency-selective fat suppressed images (46/2.5; one signal acquired; flip angle, 40°; section thickness, 3 mm; section overlap, 1.5 mm; no gap; field of view, 180 mm; acquisition matrix, 205×256; and number of sections, 80), and transverse intermediate weighted (2500/7.1) and T2-weighted (2500/40) turbo spin echo fat-suppressed images (number of signals acquired, two; section thickness, 2 mm; no gap; field of view, 180 mm; acquisition matrix, 205×256; and number of sections, 62). Total acquisition time, which included the initial survey sequence, was 30 minutes. Protocol of examination was in line with European society of musculoskeletal radiology (ESSR). It starts with the patient in supine position and slightly externally rotates the foot by about 10-15 degrees to stretch the anterior cruciate ligament. Pack some cushions around the knee to help it stay motion free. A small cushion under the ankle helps to keep the leg straight. Evaluation of the knee including the patello-femoral joint, medial and lateral compartments as well as related tendons and ligaments and the popliteal fossa is performed with a high resolution proton density sequence acquired in 3 planes: Axial, Sagittal and Coronal. Evaluation of bone marrow for contusion requires a T2 fat saturation sequence in either coronal or sagittal planes. If the patient has a suspicious mass then T1 fat saturation images are helping to determine if the mass is benign or malignant and better delineate its full extent. Obtained MRI images were diagnosed by an experienced musculoskeletal radiologist for the presence of ligament injury, tear, strain and laxity, as well as menisci degeneration and tear, Joint effusion, subchondral and bone marrow edema, bony contusion, bursitis, baker cyst and tumor were noted in all patients.

Statistical analysis

Data were expressed in percentages in comparison tables and graphs. Statistical analysis was performed using Microsoft Excel Software and the standard Statistical Package for the Social Sciences version 15 for windows.

RESULTS

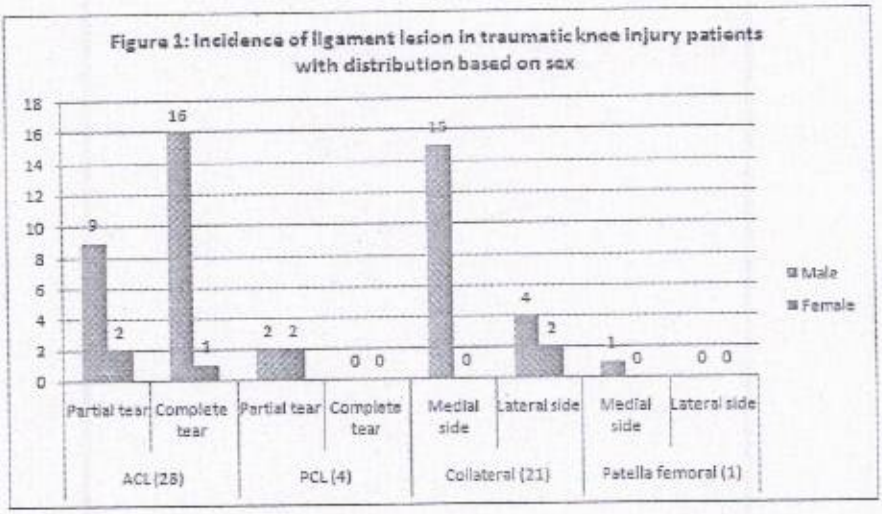
Total 63 patients were recruited with in a study period of 1 year. MRI of symptomatic or traumatic injured knee was conducted. Of these 63 patients 56(88.89%) were male and 7 (11.11%) were female, with male to female ration of 8:1. Mean age of the patients was 31 years (range 11 to 59 years). They were classified into age groups and out of these groups 28 were found to be in age group between 21-30 years. In this age group 2 were female and 26 were male patients. Table 1 Effusion was most frequently found in symptomatic knee constituting 94.64% followed by bone marrow edema (69.64%), and ACL (50%). Patello femoral ligament injury (1.79%) was found to be least affected Table 2. Figure 1 shows the incidence of ligament lesion in the form of partial/complete tear or medial/lateral side injury and figure 2 shows menisci injury in different grades. These injuries are distributed according to sex.

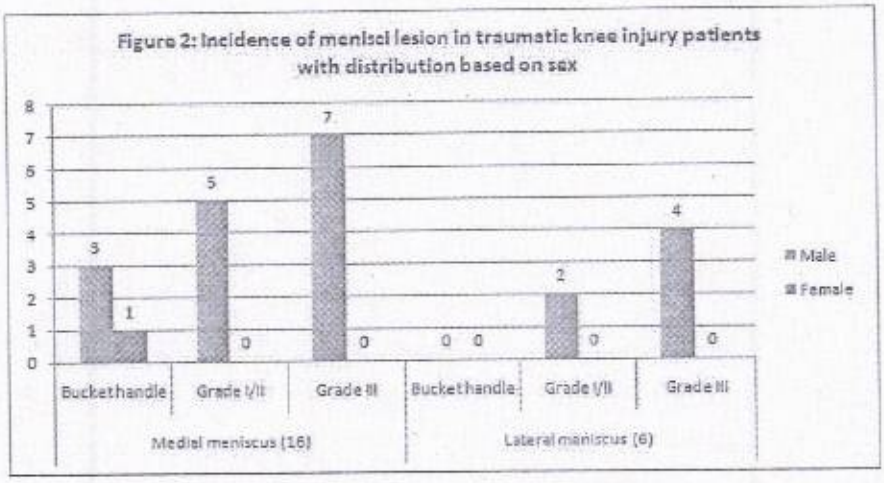
Table 1. Distribution of patients according to age and sex

Age group	Male	Female
<10	0	0
11-20	8	2
21-30	26	2
31-40	13	1
41-50	6	2
51-60	3	0
>60	0	0

Table 2. Incidence of all lesion detected by MRI in traumatic knee injury patients

Sr. No.	Knee lesion	Male	Female	Total Patients (56)
1	Anterior Cruciate Ligament (ACL)	25	3	28 (50%)
2	Posterior Cruciate Ligament (PCL)	2	2	4 (14%)
3	Menisci injury (MI)	21	1	22 (39.29%)
4	Collateral ligament (CL)	19	2	21 (37.5%)
5	Patello femoral ligament (PFL)	1	0	1 (1.79%)
6	Bone Contusion/ marrow edema	36	3	39 (69.64%)
7	Joint effusion	48	5	53 (94.64%)





DISCUSSION

MRI is invaluable in preventing unnecessary surgery, and recommends it whenever ligamentous injury is suspected. Also, there are studies that support the view that the diagnostic accuracy of the MRI could affect in a critical way the treatment pathway of knee injuries. A lot of surgeons tend to suppose that MRI is an accurate, non-invasive diagnostic method of the knee injuries, adequate to lead to decisions for conservative treatment and save a patient from unnecessary arthroscopy (Zhang and Jordan, 2010). This could be because of more activities in young males as compared to females and are more prone to road traffic accidents and frequent injuries during sports. Fifteen percent of physical activity–related injuries are found in the knee, and the risk of sustaining a knee injury is especially high in the age group of 15 to 25 years (Haapasalo *et al.*, 2006). Joint Effusion was found to be most frequent lesion in symptomatic knee constituting 94.64%. In another study joint infusion was reported in 63.8% (Mansour *et al.*, 2015). Higher percentage of joint effusion in our study shows that we tried to include even small effusion where predominant injury could be ligament or menisci and one another could be that in our study most of the patients were of recent history of trauma.

Amongst the ligament injury ACL was found be highest approximately 50% in patients with complete tear in 57.14%. This much percentage of ACL injury in our study could be explained because in our study most of the injury found in young male patients and this type of injuries are mostly found in sports person (Gianotti *et al.*, 2009). One study conducted in 2006 also shown ACL as the most common injured ligament. (Majewski *et al.*, 2006) Collateral ligament injury was found in 37.5% patients with medial side injury represents in 71.43%. One study has also shown that highest incidence of complete tear in ACL (Oei *et al.*, 2005). Menisci injury was found in 39.29% patients. In our study most of the menisci injury was found in young male as compared to female only one. Similar results have reported by other studies too of higher incidence of menisci injuries in young male (Nikolaou *et al.*, 2008; Khanda *et al.*, 2008). Amongst the menisci injury medial meniscus injury was found be highest approximately 72.72 % with grade III in 43.75%. Lateral meniscus injury was found in 27.28 % patients with grade III in 66.67%. This results are consistent with another study where medial menisci lesion were common than lateral menisci (Boks *et al.*, 2006). Grade I/II injury (signal changes) are less common in our study because these are not true tear and mostly occur with degeneration changes in

knee joint and more common in 3rd and 4th decade (Stoller *et al*., 1987) and in our study most of the patients were in age group 21-30.

Conclusion

To conclude, amongst ligament injury ACL was found to be most affected ligament and medical meniscus was found to be most commonly affected menisci in traumatic knee injury patients. Joint effusion and marrow edema were found to be associated in most of the cases.

ABSTRACT

Background: Peripheral vascular disease is diagnosed by definitive history of intermittent claudication or if one or more of peripheral pulses are absent in one or both lower limbs. Diagnostic testing for peripheral vascular disease must be accurate, inexpensive, widely accessible, easy to perform and preferably non-invasive. A variety of non-invasive techniques are available to detect the presence of peripheral vascular disease as well as to localize areas of stenosis, assess severity of disease and follow patients for disease progression or response to therapy. In this study we compare the specificity and sensitivity of ankle brachial pressure index with colour Doppler ultrasound for diagnosis of peripheral vascular disease in type 2 diabetes.

Methods: This prospective study was carried out in the department of General surgery, GMCH, Udaipur, Rajasthan, India, from September 2014 to February 2016 after taking the permission from institutional ethical committee. A total of 50 patients were selected. The selected patients were evaluated by detailed clinical history, physical examination, local examination, ankle brachial pressure index (ABPI), colour doppler study and other relevant investigations. The ABPI ratio was calculated in every patient and an ABPI less than 0.9 in either foot was defined to have PVD. Colour duplex ultrasound was done in all selected patients. Imaging of peripheral arteries of the lower limbs was done using high resolution colour duplex ultrasound. PVD was diagnosed if the stenosis in the artery was greater than 50% or presence of occlusion.

Results: Total 50 patients having type 2 diabetes mellitus with foot infection were included and most of the patients were between 40-60 years of age (68%) with males preponderance. In our study 12 (24%) patients had normal ABPI of 1.0 to 1.29 and 22 (44%) patients were in the range of mild to moderate PVD with ABPI between 0.41 to 0.90. Colour doppler was used as a standard diagnostic test for PVD & out of 50 patients, 36 (72%) showed involvement of arteries and among them both anterior and posterior tibial arteries were involved in 12 (24%) patients. In our study colour doppler ultrasound was used as standard diagnostic method for PVD. The sensitivity, specificity, positive predictive value and negative predictive value of ABPI against colour duplex ultrasound were calculated.

Conclusions: In our study it's concluded that ABPI is a good initial screening tool for peripheral vascular disease, but some patients with significant stenosis or in whom collaterals have developed in lower extremity would be missed, if ABPI measurement alone is used for diagnosis of peripheral vascular disease.

Keywords: Peripheral vascular disease, Diabetes, Foot infections, Colour doppler ultrasound, Ankle-brachial pressure index

INTRODUCTION

Diabetes is known for its micro and macro vascular complications like retinopathy, neuropathy, nephropathy, cardiovascular and peripheral vascular diseases and infections.

The major risk factors leading to diabetic foot ulcer is poor diabetes control, which results in neuropathic and vascular changes. Currently, foot problems are an important cause of morbidity in diabetes. Foot ulceration precedes the majority of amputation in diabetics. Diabetes accounts for up to 50% of non-traumatic leg amputations and 1% of diabetic people have undergone amputation.

Prevention and early treatment of foot ulcers require multidisciplinary teamwork from nurses, chiropodiatrists and doctors, preferably at primary care level. Rapid assessment and timely intervention can make the difference between limbs salvage and limb loss.

The diabetic foot is mainly because of peripheral neuropathy, arteriopathy and superimposed infection. Peripheral vascular diseases are a group of common degenerative (organic) and vasospastic (functional) disease processes that result in significant morbidity and are strong predictors of subsequent mortality.

Gangrene of the lower extremities as a result of advanced vascular disease is about 100 times more common in diabetics than non-diabetics. The primary cause of mortality in patients with PVD is myocardial infarction (60%), stroke (12%) and other complications of diabetes. A significant cause of morbidity in patients with peripheral vascular disease in diabetics is ischemic limb loss. Approximately 2% of non-diabetic patients with intermittent claudication require amputation. This rate increases to 7% for patients with diabetes mellitus.

According to American Diabetes Association revised criteria diabetes is diagnosed by.[1]

Criteria for the diagnosis of diabetes mellitus

- Symptoms of diabetes plus random blood glucose concentration ≥11.1 mmol/L (200 mg/dL) or
- Fasting plasma glucose ≥7.0 mmol/L (126 mg/dL) or
- A1C >6.5% or
- Two-hour plasma glucose ≥11.1 mmol/L (200 mg/dL) during an oral glucose tolerance test.

Risk factors for the development of diabetic peripheral vascular disease are genetic predisposition, age, duration of diabetes, smoking, hypertension, hypertriglyceridemia, hypercholesterolemia, truncal obesity, hyperinsulinemia, proteinuria, dialysis and drugs (β-blockers, ionotropic agents). Among them most important are age, duration of diabetes, genetic predisposition and smoking. Peripheral vascular disease is diagnosed by definitive history of intermittent claudication or if one or more of peripheral pulses are absent in one or both lower limbs. The absence of pedal pulses in the presence of a palpable popliteal pulse is a classic finding in diabetic arterial disease because of the selective involvement of the tibial arteries below the knee.

Diagnostic testing for peripheral vascular disease must be accurate, inexpensive, widely accessible, easy to perform and preferably noninvasive. A variety of noninvasive techniques are available to detect the presence of peripheral vascular disease as well as to localize areas of stenosis, assess severity of disease and follow patients for disease progression or response to therapy.

These are:

- ABPI test.
- Doppler ultrasonography and color flow imaging.
- MRI and MR angiography.
- CT angiography.

The ankle-brachial pressure index (ABPI) is the ratio of systolic pressure at the ankle to that in the arm. The highest pressure in the dorsalis pedis, posterior tibial or peroneal artery serves as the numerator, with the highest brachial systolic pressure being the denominator.[2]

According to American College of Cardiology and American Heart Association, ABPI ratios are interpreted as follows:

>1.30: Non-compressible vessels
1.00 to 1.29: Normal
0.91 to 0.99: Borderline (equivocal)
0.41 to 0.90: Mild to moderate PVD
0.00 to 0.40: Severe PVD[3]

The recent ACC/AHA practice guidelines for PVD management recommend that a resting ABPI should be obtained for the following group of patients:

- Individuals with suspected PVD due to exertional leg symptoms or non-healing wounds.
- Individuals aged 70 years or old.
- Individuals between 50 and 70 years of age who have a history of tobacco use or diabetes.
- Individuals with diabetes who are younger than 50 years and who have additional risk factors for PVD such as smoking, hypertension, hyperlipidemia or diabetes of >10 yrs duration.

Arterial duplex ultrasonographic examination of the lower extremities can be used to diagnose PVD. It is especially helpful in determining the location of disease and in delineating between stenotic and occlusive lesion, an added benefit when preparing for an intervention. Gray scale imaging is used to characterize the morphology of the vessel, ascertain the presence or absence of plaque & assess plaque calcification and characteristics. Management of diabetic foot includes

improvement of patient's nutrition, correction of anemia and strict glycemic control. Risk factors like smoking, hypertension, hyperlipidemia should be under strict control. The offloading is avoidance of all mechanical stress on the affected limb. The wounds should be swabbed and cultured. The surgical probing, drainage and debridement should be done under antibiotic coverage.

The arterial angioplasty, stenting, endarterectomy or arterial bypass is done for revascularization of diabetic foot. In recent years, several new treatment strategies have been developed to stimulate wound healing in the diabetic foot ulcers. These are topical growth factors, extracellular matrix products, bioengineered human skin, and hyperbaric oxygen therapy, granulocyte macrophage colony stimulating factor and collagen granules.

METHODS

This study was conducted on patients of type 2 diabetes mellitus with foot infection admitted in Geetanjali Medical College & Hospital, Udaipur from September 2014 to February 2016. A total of 50 patients were selected. The selected patients were evaluated by detailed clinical history, physical examination, local examination, ABPI, colour Doppler study and other relevant investigations. The ankle brachial pressure index ratio was calculated in every patient and an ABPI less than 0.9 in either foot was defined to have PVD.

Blood pressure recordings were done on the brachial pulse in the upper limb by palpatory method using the usual sphygmomanometer, cuff and brachial systolic pressure noted. In the lower limb similar recordings were done by using the same cuff around the calf and palpating dorsalis pedis and posterior tibial pulses. The mean of these two readings was taken as the ankle pressure. All readings being done in supine position after ten minutes rest.

ABPI was calculated as:

$$\text{ABPI} = \frac{\text{Systolic ankle pressure}}{\text{Systolic brachial pressure}}$$

Colour duplex ultrasound was done in all selected patients. Imaging of peripheral arteries of the lower limbs was done using high resolution colour duplex ultrasound.

The superficial femoral artery was traced up to the popliteal fossa and the profound was evaluated in its proximal segment. The popliteal vessels, anterior tibial, peroneal, posterior tibial and dorsalis pedis were also evaluated. PVD was diagnosed if the stenosis in the artery was greater than 50% or presence of occlusion.

Statistical analysis

All data were tabulated and statistical analysis was performed. The sensitivity, specificity, positive predictive value and negative predictive value of ABPI against colour duplex ultrasound were calculated. In brief, these were calculated as follow:

$$\text{Sensitivity} = \frac{\text{Number of true positive subjects}}{\text{Total number of subjects diagnosed as PVD by CDU}}$$

$$\text{Specificity} = \frac{\text{Number of true negative subjects}}{\text{Total number of subjects Negative for PVD as diagnosed by CDU}}$$

$$\text{Positive predictive value} = \frac{\text{Number of true positive subjects}}{\text{Total subjects diagnosed as pvd by ABPI}}$$

$$\text{Negative predictive value} = \frac{\text{Number of true negative subjects}}{\text{Total subjects diagnosed as PVD by ABPI}}$$

RESULTS

This study was conducted in Geetanjali Medical College and Hospital, Udaipur, Rajasthan, India. On 50 patients suffering from diabetes mellitus with foot infections.

Age distribution

Out of the 50 patients, 34 (68%) were aged between 40 to 60 years of age, 4 (8%) were aged below 40 years and 12 (24%) patients were aged more than 60 years. Youngest patient was 36 years old & oldest patient was 73 years old (Table 1).

Table 1: Age distribution.

Age (Years)	No. of patients	Percentage
Below 40	04	08
40-60	34	68
Above 60	12	24

Sex distribution

In our study out of 50 patients, 36 (72%) were males & 14 (28%) were females. The male to female ratio was 2.5: 1 (Table 2).

Table 2: Sex distribution.

Sex	No. of patients	Percentage
Male	36	72
Female	14	28

Table 3: Associated factors.

	Yes		No	
	No. of patients	Percentage	No. of patients	Percentage
Walking bare feet	32	64	18	36
H/o smoking	24	48	26	52
H/o ulcer or amputation	18	36	32	64

Associated factors

Out of 50 patients, 32 (64%) patient were in a habit of walking bare feet either at home or at work and 24 (48%) patients were smokers. It shows that walking bare feet was associated with increased incidence of diabetic foot (Table 3).

Ankle Brachial Pressure Index

ABPI in normal patients is between 1.0 to 1.29 and in our study 12 (24%) patients had ABPI of >1.0. ABPI between 0.91 to 0.99 indicates borderline PVD and in our study 10 (20%) patients had ABPI between 0.91 to 0.99. In our study, 22 (44%) patients were in the range of mild to moderate PVD with ABPI between 0.41 to 0.90 (Table 4).

Table 4: ABPI.

ABPI	No. of patients	Percentage
>1.0	12	24
0.91 to 0.99	10	20
0.41 to 0.90	22	44
<0.40	06	12

Colour Doppler study

In our study, colour Doppler was used as standard diagnostic test for PVD. Out of 50 patients, 36 (72%) showed involvement of arteries & 14 (28%) patients showed normal study (Table 5).

Table 5: Colour Doppler study.

Colour Doppler study	No. of patients	Percentage
Involvement of arteries	36	72
Normal study	14	28

Involvement of arteries in colour Doppler study

In our study out of 50 patients colour Doppler shows involvement of arteries in 36 (72%) patients. Out of 36 patients, calf vessel involvement was seen in 27 (54%) patients. Only anterior tibial artery was involved in 9 (18%) patients, posterior tibial in 6 (12%) patients and both anterior and posterior tibial were involved in 12 (24%) patients. Popliteal artery involved in 4 (8%) patients and superficial femoral artery in 5 (10%) patients (Table 6).

Table 6: Involvement of arteries in colour Doppler study.

Involvement of arteries	No. of patients	Percentage
Anterior tibial only	09	18
Posterior tibial only	06	12
Both anterior and post tibial	12	24
Popliteal	04	08
Superficial femoral	05	10

Sensitivity and specificity of ABPI vs colour Doppler ultrasound

In our study, out of 50 patients, ABPI showed PVD in 28 (56%) patients and absence of PVD in 22 (44%) patients. Colour Doppler ultrasound was used as standard diagnostic method for PVD in this study. Colour Doppler showed PVD in 36 (72%) patients. Out of the 36 patients diagnosed to have PVD by CDU, only 26 were categorized as PVD by ABPI. Thus 10 patients would have remained undiagnosed if ABPI alone was used for diagnosis. Conversely 2 patients out of the 28 patients diagnosed as having PVD by ABPI were classified as normal by the CDU. Hence sensitivity of ABPI is 72.22 % & specificity of ABPI is 85.71% in comparison with colour Doppler ultrasound. Positive predictive value of ABPI is 92.85% and negative predictive value of ABPI is 54.54% (Table 7).

Table 7: Sensitivity and specificity of ABPI vs colour Doppler ultrasound.

ABPI	Colour Doppler ultrasound		Total
	Abnormal (+)	Normal (-)	
Abnormal (+)	26	02	28
Normal (-)	10	12	22
Total	36	14	50

Amputation

In this study, out of 50 patients, 17 (34%) patients required amputation, out of which 10 (20%) patients required minor amputation of toes and 7 (14%) required major amputation (Table 8).

Table 8: Amputation.

Amputation	No. of patients	Percentage
Minor	10	20
Minor	07	14
Total	17	34

DISCUSSION

The spectrum of diabetic complication is very wide, and to some extent unpredictable. Advances insulin therapy and oral hypoglycemic agents have led to an increase in the life span of patients affected with diabetes mellitus. This has in turn led to an increase in the incidence of complications of diabetes like retinopathy, neuropathy, vascular diseases and nephropathy. Foot problems are the most common indications for hospital admission in diabetes. They account for approximately 20 percent of all hospital admission in diabetics.

Peripheral vascular disease plays an important role in the pathogenesis of foot ulcer and good circulation is required for early healing. Hence there is a need for early diagnosis of peripheral vascular disease in diabetics with foot infections. The noninvasive tests are of great value in assessing the vascular supply of the foot and evaluating the healing potential of foot ulcers and local amputations. Among these tests ABPI is one of the easiest, most widely reproducible and cost effective method of determining the degree of diminished arterial circulation in lower limb.

Earlier studies by Strandezz DE, Bell JW[4] have suggested ABPI as a reliable method for diagnosis of PVD and ABPI value of <0.9 has 98 % sensitivity compared to angiography. Premalatha et al[5] in their study compared CDU and ABPI measurement in 100 type 2 diabetic patients with foot infections and found that ABPI had sensitivity of 70.6% and specificity of 88.5%. They concluded that ABPI is a good initial screening tool but some patients with significant stenosis would be missed, if ABPI alone is used for diagnosis of PVD.

In our study, ABPI measurement had 85.71% specificity and 72.22% sensitivity as compared to 88.5% and 70.6% in Premalatha et al[5] study (Table 7). The low sensitivity indicates that ABPI measurement would miss some of the patient with PVD. The reason being, there may be higher ABPI values in spite of stenosis probably due to collateral circulation that maintains blood flow to the lower limb beyond the obstruction. Higher ABPI values also suggest calcification of vessels.

If ABPI alone is used, many patients with severe stenosis in the peripheral artery will be diagnosed as normal. But in view of the ease of performing the test and its low cost, ABPI would be a good initial screening test.

If ABPI is abnormal, the diagnosis of PVD is almost certain. If ABPI is normal and the patient is asymptomatic no further testing is required because even if PVD is present it is likely to be clinically insignificant. If however, there are clinical symptoms of PVD and the ABPI is normal, a CDU should be performed before PVD is definitely excluded. CDU however needs more expensive equipment, is technically more difficult, needs a highly skilled radiologist to perform, is not available widely and cannot be carried out at smaller centers.

Venkata et al[6] in his study showed that maximum number (54%) of patients were in the age group of 51-60 years and 65% patients were male. In our study, 34 (68%) patients were between the age of 40 to 60 years and 36 (72%) patients were male patients. Bild et al[7] stated that alteration in foot dynamics due to ulceration or amputation can cause the abnormal distribution of plantar pressures and results in formation of new ulcers. In our study, 18 (36%) of patients had previous history of amputation or ulcers. Also 32 (64%) of patients were in a habit of working bare feet either indoor or outdoor (Table 3).

Logerfo and Coffman[8] stated that the arterial occlusion commonly involves the tibial arteries (calf vessels). In our study, involvements of peripheral arteries were found in 27 (54%) patients (Table 6); out of that involvement of anterior and posterior tibial both were present in 12 (44.4%) patients. In our study, 17 (34%) patients required amputation. In a similar study by Zafar,[9] 17 (36%) patients out of 48 patients required amputation of minor and major types. In Reiber,[10] study out of 50 patients, 20 (40%) required amputation.

CONCLUSION

In our study it's concluded that ABPI is a good initial screening tool for peripheral vascular disease, but some patients with significant stenosis or in whom collaterals have developed in lower extremity would be missed, if ABPI measurement alone is used for diagnosis of peripheral vascular disease.

Abstract

Introduction: *Exact determination of gestational age is crucial for appropriate antepartum care as well as successful outcome of deliveries. The exact knowledge of gestational age is also important for undertaking various diagnostic procedures that needs to be performed within a narrow range of a particular gestational age. While fetal biometry is one of the most common method of determination of gestational age and weight alternative methods such as measurement of placental thickness can also be used for determination of gestational age and other parameters in doubtful situations. We conducted this cross sectional study to find out whether placental thickness can be used for estimation of gestational age and other parameters.*

Materials and Methods: *This was a cross sectional study in which 403 pregnant women in their second and trimester were included on the basis of a predefined inclusion and exclusion criteria. Gestational age and other fetal parameters were determined on the basis of bio-physical parameters. The placental thickness was measured at the level of umbilical cord insertion and maximum thickness was determined in the cross section. Statistical analysis was done using SPSS software. P value less than 0.05 was taken as statistically significant.*

Results: *In this study of 403 women the mean age was found to be 28.36 +/- 7.6 years. In majority of the cases placenta was either anterior (42.4%) or posterior (30.5%). Placental thickness of 36.51 ±\ 4.67 was found to be corresponding to the gestational age of 37 weeks (Full-Term Gestation). The mean placental thickness was found to be having a linear relationship with gestational age and other fetal parameters and statistical association between placental thickness and gestational age as well as other fetal parameters was found to be significant.*

Conclusion: *Placental Thickness can be used for determination of gestational age and other fetal parameters in doubtful cases.*

Keywords: *Placental Thickness, Second and Third Trimester, Gestational Age, Biometry.*

Introduction

Accurate estimation of foetal maturity is one of the most common problems that an obstetrician faces. Estimation of gestation age (foetal maturity) is of critical importance in clinical practice not only to ensure appropriate management of new-

borns but also to distinguish pre-term from term infants[1]. The best antepartum care and successful deliveries of babies always revolve around the accurate knowledge of the gestational age (GA). It is also very important to differentiate between normal and growth restricted foetuses. The exact knowledge of gestational age is also important for undertaking various diagnostic procedures (Chorionic villous sampling and amniocentesis) that need to be performed within a narrow range of a particular gestational age. While fetal biometry is one of the most common method of determination of gestational age and weight alternative methods such as measurement of placental thickness can also be used for determination of gestational age and other parameters in doubtful situations[2].

Proper assignment of expected date of delivery is of utmost importance in the interpretation of biochemical tests such as screening for the expanded biochemical markers (HCG, Alfa Fetoprotein and the oestrogen and progesterone level) for the risk assessment of various foetal anomalies, to plan and execute therapeutic manoeuvres and to determine the optional management in certain difficult situations like intrauterine growth restriction, gestational diabetes and Rh disease[3]. Moreover when an anomaly is detected, the interventional modality which is used, is influenced by the gestational age. All the important clinical decisions, which include caesarean section, elective labour induction, etc., depend on the knowledge of gestational age. Hence an accurate establishment of expected date of delivery is fundamental to the management of high risk pregnancies[4].

Introduction of obstetric ultrasonography in the early 1970s led to a marked improvement in the evaluation of foetal and placental anatomy, as well as foetal growth. Now, it appears as the most effective technique to estimate gestational age (GA). Fetal biometry (Biparietal diameter, Head circumference, abdominal circumference and femur length) is routinely used to determine gestational age after 12 weeks of pregnancy[5].

It is important to know that ultrasonography is highly observer dependent investigation.

Moreover the position of the baby many times makes it difficult to accurately take biometric parameters. Many authors, such as Wolfson et al, have concluded that the bi-parietal diameter was not reliable in the foetuses which had premature rupture of membranes. So, there is a need of another parameter for supplementing the gestational age estimation with minimal error. Placental thickness is an important parameter in estimating fetal growth, the placental thickness changes with increasing growth of fetus. It is different in all 3 trimesters. So, it can be used as another parameter to estimate gestational age (GA). Various studies have reported that the placental thickness not only reflects the gestational age of the fetus but also may be useful in diagnosing conditions such as intrauterine growth restriction (placental thickness < 25mm) or gestational diabetes (Placental 10 thickness > 40mm)[6].

We conducted this cross sectional study to find out whether placental thickness can be used for estimation of gestational age and other parameters.

Materials and Methods

This was a Cross sectional study with an analytical design carried out amongst pregnant women referred to radio-diagnosis department of a tertiary care medical college situated in an urban area. 403 Pregnant women who were referred for Level II obstetric ultrasound scan (in their 2nd and 3rd trimester) were included in this study on the basis of a predefined inclusion and exclusion criteria. Informed consent was obtained from all the women. Previous scans, if already done, were analysed and if any abnormality was detected in previous scan it was noted down.

Study Protocol

After taking a detailed history, the antenatal women were examined for placental thickness, gestational age, Biparietal Diameter (BPD), the Abdominal Circumference (AC), the Head

Circumference (HC), the Femur length (FL) by USG using 1-5 MHZ convex array transducer.

Subjects were scanned with moderately distended bladder in supine position. The transducer was placed on the skin surface after applying the coupling agent. Placental thickness in mm was measured at the site of cord insertion. The transducer was oriented to scan perpendicular to both the chorionic and basal plates, as tangential scan would have distorted the measurement of thickness of placenta. All placental measurements were taken during the relaxed phase of uterus as contractions can spuriously increase the placental thickness.

Collected data (Annexure I) was entered in the MS Excel spread sheet, coded appropriately and will be cleaned for any possible errors. Analysis was carried out using Statistical package for social sciences (SPSS) for Windows version 17.0, Released 2008 (SPSS Inc., Chicago, IL). Normally distributed data was presented as means and standard deviation, or 95% confidence intervals (CI). Placental thickness was measured in mm along with their respective standard deviation (SD) were computed for each gestational age from 12 to 40 weeks. The 95 % C.I was calculated. Correlational analysis including Pearson's and Spearman's analysis was used for the multiple variables to establish the degree of relationship between PT, FL, HC, AC & BPD. The level of significance was determined and p value of <0.05 was taken as statistically significant.

Inclusion Criteria

1. Singleton pregnancies, 12-40 weeks.
2. The known last menstrual period.
3. A history of regular menstruation.
4. No known maternal and fetal chromosomal /structural abnormalities.

Exclusion Criteria

1. Pregnant females not knowing their LMP.
2. Patients with irregular menstrual cycle.
3. First trimester gestations
4. Multiple pregnancies.
5. Known cases of Eclampsia, PIH, gestational diabetes or maternal systemic diseases.

Results

In this study of 403 women the most common age group was found to be between 26- 30 years (47.9%) followed by 20-25 years (30.8%) and more than 30 years (20.6%). Only 3 patients (0.7%) were found to be below 20 years of age.

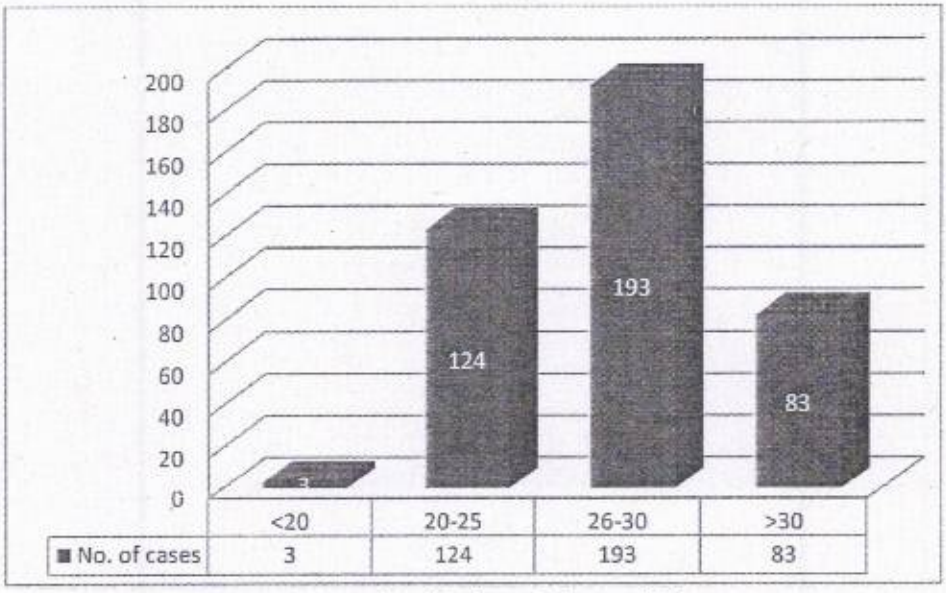

Figure 1: Age distribution of the studied cases

It was observed that in majority of the pregnant females (42%), the placenta was attached anteriorly to the uterus. This pattern was followed by posterior attachment (30%), and fundal posterior (14%) attachments as the most frequent types. Fundal attachment (1.9%) was observed to be the least common type.

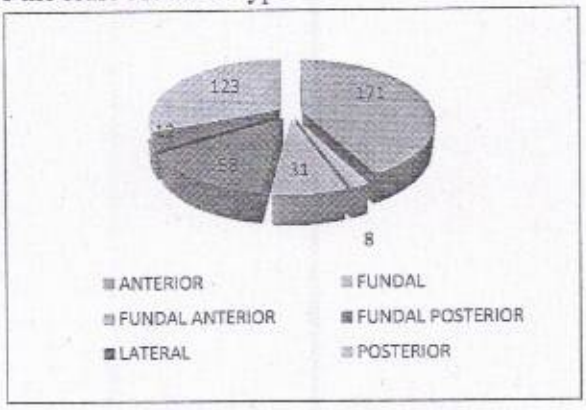

Figure 2: Location of attachment of the placenta

Pearson's analysis was used to depict correlation between the gestational age and placental thickness. The two variables depicted strong positive correlation (r= 0.967) & p-value :< 0.001 between the gestational age of 14-35 weeks whereas the placental thickness depicted statistically significant but a weak positive correlation with gestational age of >35 weeks. The range of placental thickness varied between 11-38 mm during the gestational age 14-35 weeks. The thickness of placenta varied between 30-43 mms and the mean value was about 35.35 mm when it was measured between 35-39 weeks period of gestation.

Table 1: Correlation of gestation age14-35 weeks and >35 weeks by ultrasonography and placenta thickness (mm)

	Range	Mean	SD	r	P-value
Gestational Age (weeks) by USG	14-35	25.60	6.29	0.967	<0.001 (HS)
Placenta thickness (mm)	11-38	25.34	6.26		
Gestational Age (weeks) by USG	35-39	36.19	1.17	0.432	<0.001 (HS)
Placenta thickness (mm)	30-43	35.35	3.77		

The analysis of placental thickness and gestational age showed that the mean placental thickness increases with each passing gestational week, till 37 weeks period of gestation but then a decrease in thickness was observed after 38 weeks period of gestation.

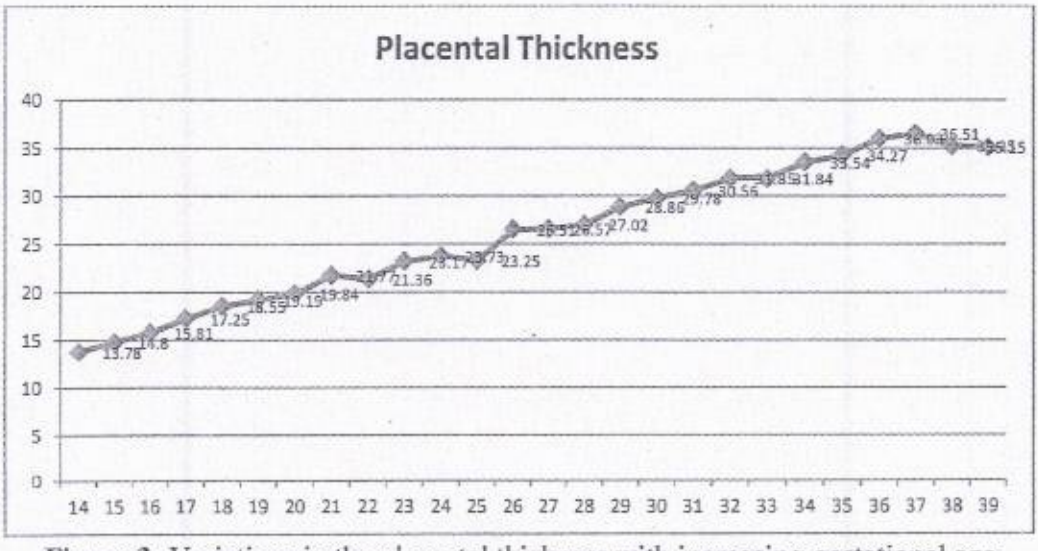

Figure 3: Variations in the placental thickness with increasing gestational age

The analysis of the variations in the placental thickness with increase in the period of gestation showed that the difference in the placental thickness with time were statistically significant with a p-value<0.001.

Table 2: Comparison of the placental thickness with gestational age

Gestational Age (Weeks)	Number Of Cases	Placental Thickness ± SD (mm)
14-20	88	17.63 ± 2.58
21-27	73	23.87 ± 2.94
28-32	91	29.87 ± 2.22
33-40	151	34.50 ± 3.42
Total	403	27.85 ± 7.19

The changes in placental thickness and other anthropometric parameters with increase in gestational age. The maximum mean placental thickness achieved was 36.51 mm at 37 weeks period of gestation. Other parameters also increased steadily and corresponded well with the actual gestational age.

33-40	151	35.13+1.83	35.42 +1.79	35.11+ 1.97	35.54 + 1.99
Total	403	28.26+7.11	28.21 +7.29	28.47+ 8.62	28.87 + 12.10
P-Value		<0.001	<0.001	<0.001	<0.001

In the second trimester of the pregnancy Placental thickness depicted maximum correlation with the gestational age(r= 0.916; p<0.001), followed by bi-parietal diameter(r= 0.907; p<0.001) and head circumference (r= 0.898; p<0.001). It depicted weak and poor correlation with abdominal circumference (r= 0.482; p<0.001) and femur length (r= 0.236; p<0.001). Femur length also depicted weakest correlation (r= 0.267; p<0.001) with the gestational age. Overall, weakest correlation was seen between femur length and abdominal circumference (r=0.149; p-value :> 0.05).

Table 5: Correlation between placental thickness, gestational age and other growth parameters; bi-parietal diameter (BPD), head circumference (HC), femur length (FL) and abdominal circumference (AC) in the second trimester of pregnancy (13-27 weeks

	Gestational Age By USG (weeks)	Placental Thickness (mm)	BPD (Weeks)	HC (Weeks)	AC (Weeks)	FL (Weeks)
Gestational Age By USG(weeks)	1					
Placental Thickness (mm)	.916**	1				
BPD (Weeks)	.955**	.907**	1			
HC (Weeks)	.959**	.898**	.953**	1		
AC (Weeks)	.512**	.482**	.500**	.510**	1	
FL (Weeks)	.267**	.236**	.281**	.269**	.149	1

In the third trimester of the pregnancy only good positive correlation was seen between the placental thickness and Bi-parietal diameter (r= 0.705; p<0.001), gestational age (r= 0.702; p<0.001), femur length (r= 0.699; p<0.001), head circumference (r= 0.696; p<0.001) and abdominal circumference (r= 0.693; p<0.001) that were depicted in weeks. Overall, excellent correlation was seen between gestational age and the head circumference in weeks (r= 0.931; p<0.001) and femur length (r= 0.931; p<0.001) and only good correlation was seen with placental thickness (r= 0.702; p<0.001)

Table 6: Correlation between placental thickness and the growth parameters; bi-parietal diameter (BPD) and abdominal circumference (AC) in the third trimester of pregnancy (28-40 weeks)

	Gestational Age By USG (weeks)	Placental Thickness (mm)	BPD (Weeks)	HC (Weeks)	AC (Weeks)	FL (Weeks)
Gestational Age By USG(weeks)	1					
Placental Thickness (mm)	.702**	1				
BPD (Weeks)	.929**	.705**	1			
HC (Weeks)	.931**	.696**	.898**	1		
AC (Weeks)	.925**	.693**	.876**	.892**	1	
FL (Weeks)	.931**	.699**	.890**	.898**	.904	1

The correlational analysis of the different fetal growth parameters and gestational age (GA) showed that GA depicted strong positive correlation with all the parameters except FL

(femur length, weeks) where it depicted week positive correlation. Femur length depicted weakest positive correlation with most of the other parameters ranging from r=0.464 to 0.531.

Table 7: Correlation matrix showing the correlation coefficient 'r' values between gestational age, Placental Thickness, Bi-parietal Diameter, Head Circumference, Abdominal Circumference and Femur Length.

	GA by USG (Weeks)	Placental Thickness (mm)	BPD (Weeks)	HC (Weeks)	AC (Weeks)	FL (Weeks)
GA by USG (Weeks)	1					
Placental Thickness (mm)	0.946	1				
BPD (Weeks)	0.987	0.945	1			
HC (Weeks)	0.987	0.942	0.982	1		
AC (Weeks)	0.805	0.771	0.799	0.802	1	
FL (Weeks)	0.560	0.531	0.563	0.559	0.464	1

The age of the pregnant females ranged between 15-46 years (mean value: 27.29 + 4.97 years). Mean gestational age of the fetuses ranged between 14-39 weeks (mean value: 28.25 + 7.15 years). (Table 12) Similarly, the Placental Thickness, Bi-parietal Diameter, Head Circumference, Abdominal Circumference and Femur Length ranged between 11-43 weeks (mean value: 27.85 + 7.19 weeks), 14-40 weeks (mean value: 28.26 + 7.11 weeks), 13-40 weeks (mean value: 28.21 + 7.30 weeks), 13-126 weeks (mean value: 28.47 + 8.62 weeks) and 13-222 weeks (mean value: 28.87 + 12.10 weeks) respectively.

Table 7: Mean values of mother's age, gestational age, Placental Thickness, Bi-parietal Diameter, Head Circumference, Abdominal Circumference and Femur Length observed during the ultrasonography

	Range	Mean+ SD
Age of pregnant Females (yrs.)	15-46	27.29 +4.97
Gestational Age By USG (Weeks)	14-39	28.25+7.15
Placental Thickness (mm)	11-43	27.85+7.19
BPD (Weeks)	14-40	28.26+7.11

Discussion

The current study presented data based on 403 mothers enrolled as study participants according to their age. Distribution of the pregnant mothers by age as well as position of the placenta was observed to be similar to several studies conducted by other researchers in the region[7].

In this study, data has been generated and analyzed for different gestational ages in the different trimesters of pregnancy. The mean PT was 23.8 (2.94) mm and 34.5 (3.42) mm in the second and third trimester, respectively. In the present study, a mean PT was 35.15 mm at 39 weeks of gestation. This was lower than to the value reported by researchers from Nigeria who reported a mean PT of 45 (6.4) mm and 42 (2.9) mm at 39 weeks of gestation[8,9]. The reason for difference can be difference in genetic structure of two populations. However, PT at 39 weeks' gestation was closer to that reported by Mital *et al.* (37.5 mm) who conducted similar work in India[10]. Further studies exploring the genetic differences in placental thickness can explain the extent and reason for differences.

Placental thickness and estimated fetal birth weight have a significantly high positive correlation in both the trimesters as noted by other researchers also[11]. The usefulness of this relationship between placental thickness and estimated fetal weight is that subnormal placental thickness for a gestational age may be the earliest indicator of fetal growth retardation.

In an Indian study, mid pregnancy placental volume was suggested to be significantly related to placental weight at birth and also the birth weight of new born independent of maternal size. Further Clapp et al evaluated placental growth and reported second-trimester placental volumes and growth rates as good predictors of size at birth in

healthy, active women. As found in other studies, a significant correlation between placental growth rate and gestational age was reported in this study as well. Significant positive correlations between placental thickness and estimated gestational in the second and third trimesters ($p < 0.05$) was also demonstrated[12].

Placental thickness was depicted to increase proportionally with each passing week of gestation. The placental thickness depicted statistically significant but a weak positive correlation with gestational age of >35 weeks. The overall thickness varied between 13.7- 36.5 mm which is lower than that reported by Noor et al[13]. The thickness of placenta varied between 34.2-35.15 mms and the mean value was about 35.4 mm when it was measured between 35-39 weeks period of gestation.

The variations in the placental thickness with increasing gestational age in 403 pregnant females evaluated during different period of gestation was observed which demonstrated an increase in mean placental thickness with each passing gestational week, till 37 weeks period of gestation followed by a decrease in thickness after 38 weeks period of gestation. This implies that PT increases linearly and attains its maximum thickness at 39 weeks of gestation. The maximum PT obtained during this study was less than the value of 47 mm reported by a Nigerian study[9]. A few previous reports from non- Indian populations reported normal placenta to be lower than <40 mm in thickness at any stage of pregnancy[14,15]. This implies that placenta of the Indian population is normally thinner than Nigerian populations and is similar to Caucasian populations.

The results of the present study are consistent with the observations made by authors of previous studies[16]. Average placental thickness was reported to be roughly equivalent to gestational age (in weeks). (23, 34) They reported that the mean thickness of the placenta was 3.90±1.1cm which increased till 38 weeks of gestation, thereafter decreased. This finding is consistent with our findings. Mital et al. also found similar trends in the values of mean placental thickness (in mm) and increasing in gestational age (in weeks). The placental thickness coincided almost exactly with the gestational age in weeks in two studies from India[17]. Baghel et al. reported that placental thickness in millimeters almost coincides with gestational age in weeks at 24 weeks (24.5 mm at 24 weeks), 32 (31.8 mm at 32 weeks) and 36 weeks (35.5 mm at 36 weeks)[18]. Nyberg and Finberg also reported that as a rule of thumb, placental thickness parallels gestational age (in weeks)[19]. Similarly in a recent study by Karthikeyan et alhad reported that placental thickness can be used as a predictor of the gestational age, and additionally suggested that subnormal PT for the corresponding GA should be evaluated for any disease condition[20].

Conclusion

There is a strong linear relationship between placental thickness and gestational age and other fetal parameters in second and third trimester pregnancy. The relation was found to be statistically significant. Placental Thickness can be used for determination of gestational age and other fetal parameters in doubtful cases.

ABSTRACT

Objective: We retrospectively evaluated anatomic variants and anomalies of coronary arteries and found their incidence in 106 patients with the help of the 64-slice Computed Tomography Angiography (CTA).

Materials and Methods: CT data of 106 patients who underwent 64-slice CT angiography (CTA) because of screening or suspected coronary artery disease were retrospectively reviewed in Department of Radiology, Geetanjali Medical College and Hospital, Udaipur. In each case, anatomic variants and anomalies were investigated.

Results: The coronary artery system was right dominant in 85%, left dominant in 12% and co-dominant in 2.8 % of the cases. Ramus intermedius was present in 16.9%. Conus artery from Right coronary artery found in 72.6%, with a same ostium was observed in 10.3 % and in 16.9 % conus arteries originating with separate ostia were visualized. The sinus node artery (SNA) originated from the right coronary artery (RCA) in 66.9% and from the Left Circumflex artery (Cx) in 33%. LMCA was absent in 0.9%. Myocardial bridging was observed in 11.3%.

Conclusion: Complex anatomy of the coronary artery tree can precisely be showed by 64-slice CTA. This technology is an appropriate substitute to conventional coronary angiography in distinguishing coronary artery variations and anomalies.

Keywords: Anatomic Variations, Coronary Artery

INTRODUCTION

Coronary artery anomalies can be fatal during or subsequent to heavy physical activity, usually in young population. The information of coronary anomalies is also crucial for cardiologist before performing any invasive procedure in coronary artery disease patients. The coronary anomalies cause 11.8% deaths in young athletes in USA.(1) An another study depicted that 12% of sports-related sudden cardiac deaths and 1.2% of non-sports-related deaths were originated from coronary abnormalities in 14 to 40 year-old persons. (2)

Screening of coronary anomalies in population is becoming viable with Contrast-enhanced CT angiography. In comparison with Conventional angiography, coronary CTA has developed into an imperative non-invasive modality in the diagnosis of coronary artery disorders. High temporal and spatial resolution capabilities of multislice computed tomography (MSCT) scanners enable detailed 3D visualization of complex coronary artery anatomy without motion artefact. The introduction of new generation MSCT, making novel, detailed coronary artery studies possible. The origin, course, variations and anomalies of the

coronary artery along with, the anatomy of the heart can now be meticulously studied with coronary CTA.(3,4) Furthermore, radiologists now have more skill in interpretation of images on normal anatomy in terms of anatomic anomalies and their cross-sectional images, which shows the way to improved diagnostic precision.(5) In this study, we aimed to recognize the 64-slice CTA appearance of the anatomic variations and anomalies of the coronary arteries and find out their incidence in a population of 106 patients.

MATERIALS AND METHODS

Population

CT data of 106 patients (91 male, 15 female, , range 31–78 years), who underwent 64-slice coronary CTA from January 2007 to December 2012 in Department of Radiology ,GMCH, Udaipur, were retrospectively assessed for anatomical variations and anomalies of coronary arteries. Patients were included who were advised by clinicians for coronary CTA screening or suspected coronary artery disease (CAD).The Institutional Review Board approved the study protocol.

CT scan and reconstruction parameters

All evaluations were carried out with a 64-slice CT scanner (Sensation 64, Siemens- Forcheim, Germany) with the subsequent parameters: slices/collimation 64/0.6 mm, rotation time 330 ms, effective temporal resolution (with 180° algorithm) 165 ms, 120 kv, 950 mAs, table feed/s 11.63 mm, effective slice thickness 0.6 mm, reconstruction increment 0.3 mm, field of view (FOV) 140–180 mm, isotropic voxel resolution of $0.4 \times 0.4 \times 0.4$ mm.

Blood urea and serum creatinine levels were estimated before the procedure. Patients were premedicated with tablet propronalol (40 mg); those have a heart rate more than 75 beats/min one hour before the scan. Sublingual nitro-glycerine was also given to the patient just before the scan. After sensitivity test a bolus of 100 ml of high iodinated contrast material (350 mg/ml ultarvist German remedies) was injected with a flow rate of 5 ml/s, followed by a 40-ml saline chaser into an antecubital vein of the right arm. Synchronization between arterial route of contrast and coronary CTA was done with the help of bolus-tracking technique. Collection of data were done in end-diastolic phase (from -300 to -450 ms just prior the peak of the successive R wave) or end-sistolic phase by retrospective gating to get a clear image of the right coronary artery (RCA).

Image analysis

Image analysis was carried out to another workstation where the reconstructed Images at optimal phase were transferred. Interpretation of radiological images were done in axial projection initially with the following tools ,like Volume-Rendering Technique (VRT) with transparent background display, curved planar reformat (CPR), thin-slab maximum intensity projection (thin MIP) and multiplanar reconstructions (MPR).Evaluation of images starts from examining the dominance of the coronary artery , their branching pattern, the origin, course, and supplying region of the major coronary arteries were assessed. The origin of the posterior descending artery (PDA) is deciding factor for dominance pattern in coronary artery. Right dominance were defined as when PDA originating from the right coronary artery (RCA) in coronary artery systems and when PDA arising from the left main coronary artery (LMCA) were defined as left dominant. Coronary artery systems where PDA was come up from the RCA and most of part of the left ventricle's posterior wall was supplied by posterolateral branches (PLB) from the circumflex artery (Cx) were termed as co-dominant. (6)

Coronary artery anomalies were classified according to Angelini et al. They classify coronary anomalies according to their origination, course, termination and anomalies of intrinsic coronary artery anatomy. (7)

RESULTS

Prevalence of normal variations and anomalies of coronary arteries observed in this study is demonstrated in Tables 1. Total 106 patients were screened through CTA. Right dominance was revealed in 90 patients (85.0%), left dominance in thirteen (12 %), and co-dominance in three (2.8%). The Most common origin of conus artery was from RCA in 77 out of 106 cases (72.6 %), the conus artery is also originated from same ostium or the right sinus valsalva in 13/106 cases (12 %), and it had a separate ostium origin in the remaining 18 cases (16.9%). The sinus node artery (SNA) originated from the RCA in 71 cases (66.9 %) and the left main coronary artery (LMCA) in 35 cases (33 %).The Ramus intermedius branch were found in 18 cases. The variation in LAD was found as type I in 26 cases (24.5%), type II in 37 cases (34.9 %), type III in 25 cases (23.5 %) and type IV in 18 cases (16.9%).Type I is described as not supplying the apex, type II partially supplying the apex and type III supplying entire the apex and type IV wraps around the apex.

Coronary artery anomalies were observed in a total of 13 cases (57.8%). One case (0.9%) had no Left Main Coronary Artery (LMCA). Left anterior Descending (LAD) and Left Circumflex (LCx) had outflows with separate ostia from the left sinus valsalva due to the absence of the LMCA. In this case LAD and LCx originated from the sinus valsalva between the aortic annulus and sino-tubular junction and blood flow was not low or high.

The LMCA trunk presented a variable length (mean 11.35±3.3 mm, range 1.2–18.7 mm, : <1 cm (n=34, 33%), 1–2 cm (n=72, 67.9%).

When coronary arteries runs via myocardium, it is called as Myocardial bridging, was observed in 12 of 106 cases (11.3%). The mid-distal segment of the Left Anterior Descending was commonly affected by myocardial bridging.

DISCUSSION

The appropriate knowledge of coronary artery variant or anomaly is very helpful to avoid difficulties during cardiac interventions or complications during graft surgery. Angioplasty process requires a precise anatomical evaluation of the coronary artery branching for revascularization purposes. (8) Coronary anomalies are relatively asymptomatic and sometimes accidentally discovered. The coronary anomalies may be the cause of severe complications, so they are not be consider just rare. (9)

Interpretations of coronary CTA images should be commenced by the study of dominance of the coronary artery system. Earlier studies on coronary CTA examination have essentially commented on this aspect .(10,11) Co- dominance is described by different authors but there is no marked concord on co-dominance and some authors defined that if the PDA and the posterior left ventricular branches together supply blood to the infero-lateral section of the posterior septum. (11, 12) Previous studies were revealed that the rate of right dominance was 80-85%, left dominance was 7-9%, and co-dominance was 5-8%. (10, 11, 12) In our study, right dominance was found in 85%(90 cases), left dominance in 12%(thirteen cases) and co-dominance in 2.8%(three cases).The rates of right and left dominance of this study were somehow similar with the earlier studies, but the lower co-dominance rates may be clarified by the fact that different authors had no agreement on co-dominance of the coronary arteries.

The conus artery commonly originates from the RCA but it may also originate from the right sinus valsalva via a separate orifice. (13) In our study, the conus artery originates from the right coronary artery in 77(72.6 %) patients , common origin from same ostium (right conus artery and right coronary artery from right sinus of Valsalva) was seen in 11(10.3%) patients and separate ostium (aortic) origin of conus artery was seen in 18(16.9%) patients. The origin of conus artery

according to a study was, from RCA 83.1% and from same ostium 16.86%.(14) In contrast to this study our study shows a higher incidence of conus artery origin from separate ostium (10.3%).It may be because of geographical and racial difference.

In our study, it was found that the SNA originated from the RCA in 71 cases (66.9 %), from the Left Cx in 35 cases (33%). Our findings well correlated with the literature which has observed that the SNA is most commonly originated from the RCA. (14)

Anatomically LMCA has two branches, LAD and Cx but sometimes it may trifurcate and the third branch is called as Ramus intermedius which is the most common variation in LMCA. The Ramus intermedius artery itself has variable branching. The Ramus intermedius can be of two types .When it supplies the anterior wall, it is identified as a diagonal branch and when it supplies the lateral wall, it is described as an obtuse marginal branch. In our study, the Ramus intermedius variation was found in 18 cases (16.9 %), this branch is one of most common variations observed in the left coronary arterial system with an incidence rate of 33%.Our observation was lower than the previous studies. (5, 15)

The incidence of the absence of a LMCA is very low in previous studies from 0.41 to 0.52% (16, 17) however Cademartiri et al. notified a high incidence rate of 3.3%.(18) We found only one case (0.9%) of the absence of the LMCA .The incidence rate for the absence of the LMCA in our study was comparable to the former observations. (5, 15) The absence of a LMCA does not have any clinical consequences and does not affect blood flow to myocardium. Although The lack of information about this anomaly may lead to misdiagnosis for example a normal LAD and Cx can be considered stenotic mistakenly in case of the absence of a LMCA. (16) Such errors can be avoided when screening of coronary artery performed by CTA and identification of such anomalies is important before planning invasive procedure for the LMCA. (17, 19)

The coronary arteries usually have an epicardial course but occasionally they may have an intra-myocardial segment. This condition is described as myocardial bridging .The incidence rates for this have been reported as 0.5-2.5% in invasive coronary angiographies while the rates are higher (10.9-43.3%) in 64 and 128 slice CT angiographies. (14,18) Normally this does not cause a problem for a person who have it, but it may rarely result in acute myocardial infarction (MI), acute coronary syndrome, coronary spasm, rupture of ventricular septum, arrhythmia, or even sudden death. Though, in arrhythmic patients with angina, myocardial bridging should be excluded. (5,20,21)We found that the myocardial bridging was observed in a total of 12 cases (11.3%) in the current study. Myocardial bridging was most frequently observed in the mid-distal segment of the LAD. Our study revealed that CTA is very precise in detecting myocardial bridging.

Anomalies of coronary arteries may generally do not create a significant risk to myocardial perfusion but sometimes these may lead to fatal pathologies which may couse in sudden cardiac casualty and myocardial ischemia. Sudden cardiac deaths among young people after exercise or sport activity are due to coronary artery anomalies.(22) Invasive coronary angiography does not give a complete information, and the details are limited about the origin of anomalies. (23) New – generation CT modality provide an accurate and detailed information about all the of the above coronary artery variations to cardiologists.

CONCLUSION

In conclusion, the 64-slice CT is an efficient diagnostic tool to evaluate the anatomic variations and anomalies of the coronary arteries and give comprehensive and accurate information about it. The coronary CTA can replace the percutaneous invasive procedures or preoperative catheter angiography for coronary arteries, and it may also be more beneficial to patients because of its low radiation dosage relative to invasive angiography,

the opportunity to use less of a contrasting agent, the increase in the number of cross-section, test duration, shortening the improvement in temporal resolution and its non-invasive approach increasingly supports the use of this technique.

ABSTRACT

Background of the study: Wide information of the anatomy of coronary arteries is useful for a management decisions of the coronary artery disease or for systemic planning of surgery. The objective of this study is to establish variations of Conus coronary arteries which arise directly from aorta and revealing about their frequency .These findings would be of great significance in the interpretation of coronary arteriography, angiography and surgical myocardium revascularization.

Research Methodology: A total number of 111 angiograms were utilized for this study. The coronary angiographic images were evaluated in this study. The study is design to investigate the number by the mean of origin of right conus artery.

Results: The results shows the right conus artery originates from right coronary artery in most of the people 77(69.3%). In this study right conus artery originate from same ostium in 15(13.5%) individuals and from Separate ostium (aortic) origin were seen in 18(16.2%).

Conclusion: A selective Angiography is recommended for conus artery because the frequency of conus artery as the third coronary artery is 29.7% of screened cases of Cat-scan coronary angiography (CTA).

Keywords: Right conus artery (R.Con.A), right coronary artery (RCA), Ostium, pattern of origin,computed tomography Angiography (CTA)

INTRODUCTION

Two coronary arteries, the right and the left one are supplying blood to human heart in general population. Prevalence of Congenital coronary variations is are quite low, which is changing from 0.3% of autopsy reports to 1.3% of angiographic studies.(1,2) Sometimes extra coronary arteries are also present. The right conus artery (R.Con.A) considered as the third coronary artery, because it is originates as a separate artery from the anterior aortic sinus. (3) The right conus artery most frequently arises from the proximal part of the right coronary artery (RCA). The conus artery vascularises to the conus, or outflow tract, of the right ventricle and is usually found to be the first branch of the right coronary artery. (4) Several scientists have suggested that it provides a collateral connection between the right and left coronary arteries. The conus artery variation may be an advantage for the person having it. (5) Computed tomography Angiography (CTA) study facilitates the routine diagnostic workup for the management of Cardiac disorders. In Coronary artery diseases patients, it is also needed to carry out conventional angiography of the third coronary artery (6, 7). An intimate knowledge of the occurrence and distribution of conus coronary arteries is important for correct

understanding of coronary angiograms, assessment of severity and effect of coronary insufficiency, and appropriate preparation and time being myocardium revascularisation (8).The purpose of this study is to establish variations of Conus coronary arteries which arise directly from aorta and its frequency.

MATERIAL AND METHODS

The patients, who had undergone The CT coronary angiograms for various reasons during 3 years at Geetanjali medical college and hospital, Udaipur, were included in this study.

A. Exclusion criteria

Patient with high calcium score >500 were excluded.

B. CT scan and reconstruction parameters:

All examinations were performed with a 64-slice CT scanner (Sensation 64, Siemens, Forcheim, Germany) with the scan protocol described in table no.1.

C. Procedure:

Pre-procedure precautions

The patients were enquired, to rule out the presence of any drug allergy, to avoid the occurrence of any untoward anaphylactic reaction, during the procedure. Patients were advised to avoid tea and coffee a day prior to procedure. Blood urea and creatinine levels were checked before the procedure. The heart rate of patients were stabilised with an oral dose of 40 mg propronalol one hour before the scan, in whom a heart rate were greater than 75 beats/min. Sublingual nitroglycerine was given to the patient just before the scan. A bolus of 100 ml of high iodinated contrast material (350 mg/ml ULTRAVIST German remedies) was injected into an antecubital vein of the right arm with a flow rate of 5 ml/s, followed by a 40-ml saline chaser. A bolus-tracking method was employed for the synchronization between arterial route of contrast material and MSCT-CA. The patient was now shifted to the CT scanner. Adequate counselling of patients were done to reduce anxiety, to preserve the best possible heart rate of 55-60 beats /min. CT angiograms of 110 patients were studied, to see the pattern of origin of right conus artery.

RESULTS

Variation in origin of Right Conus Artery

Out of 111 patients, the right conus artery originates from the right coronary artery in 77(69.3%) patients , common origin from same ostium (right conus artery and right coronary artery) was seen in 15(13.5%) patients and Separate ostium (aortic) origin of right conus artery were seen in 18(16.2%) patients as shown in Table no.2.

DISCUSSION

The variations of number of coronary arteries are relatively common in population suggested by many scientists and could be beneficial for person or could create clinical consequences. Some authors described cases of occurrence of only a single coronary artery come up from the left (9) or the right (10) aortic sinus. This single coronary artery may be associated with cardiac complications like congestive heart failure, myocardial infarction and sudden cardiac death in young athletes (11) Hadžiselimović (12) points out those even three coronary arteries may arise independently from the right aortic sinus. Four coronary arteries were reported by Almira (2008) in one case, where both supernumerary arteries arose from the right aortic sinus.(13)

Usually in most of the cases extra coronary artery begins from the right aortic sinus. Previous studies put forward several terms for classifying this artery: adipose artery, conal artery, arteria of Vieussens, preinfundiblar or supernumerary right coronary artery (12,14,15,16). Usually this coronary artery is a branch of Right coronary artery and called as right conus artery but it has three variations according to its origin. The most appropriate term for this artery when it originate from separate ostium, is the third coronary artery.

Information about incidence of the third coronary artery are varying in different population from1.5% as stated by Lo (17) even to 62% as stated by Hadžiselimović (12).In our study right conus artery as third coronary artery was found in 29.7 % and this result correlated with Kalpana (2003) 24%, Pinar Kosar et al.(2009) 22% and difference with Susan standring (2006) 34% could be due to geographic variation (18,19,20). The other reason for this deference could be due to inability to selectively canulate conus /third coronary artery on conventional angiography.

The common origin of right conus artery with right coronary artery was observed in 13 %.This may be useful while performing conventional coronary arteriography and angiography. Gajbe et al. suggested that a preliminary aortic root injection of dye method was followed to locate the exact number of orifice of the coronary ostia, in order to prevent the fatal outcome (21). An unusual conus artery arising independently from the RCA is mainly at risk for injury from ventriculostomy or other maneuvers carried out during heart surgery (22)

According to Udaya Sankari T et al if right conus artery directly arises from the aorta (third coronary artery) than it creates double collateral circulation for intra-ventricular septum and myocardium of the left ventricle. This prevents the right coronary artery "steal" phenomenon. "Blessed are the people, those who are born with right conus artery with long branches" (23)

In our study, the third coronary artery was found in 29.7% of screened cases what is comparable with the results showed by Yamagishi [30%] (24).In this study, 69.3% of the population had the right conus artery arising from the right coronary artery and in the rest 29.7% of the individual's right conus artery either arose directly from the aorta or in common with right coronary artery. So the present study suggests that 29.7% of population needs care while performing coronary angiography to prevent fatal outcome. The third coronary artery could be very useful collateral in case of proximal RCA stenosis.

CONCLUSION

A non-invasive imaging of small mobile structures, such as coronary arteries has possible with the new advancement in imaging technology, such as multidetector ECG gated CT. Coronary artery diseases have high morbidity, mortality, and socioeconomic burden on society. A non-invasive detection of Right conus artery stenoses is corner stone in management of coronary artery disease with help of 64-slice computed tomography Angiography (CTA).

A selective Angiography is recommended for conus artery because the frequency of conus artery as the third coronary artery is 29.7% of screened cases of CTA. The third coronary artery is appropriate term to categorize extra coronary artery which arises separately from the right aortic sinus. The third coronary artery is an extra artery or god blessing for whom that has it and be very valuable for collateral perfusion.

ABSTRACT

Background: In patients of knee pain diagnosis has utmost important for treatment and to avoid unnecessary surgery. MRI is a non-invasive procedure in evaluation of knee joint. So this study was planned find out the prevalence of abnormalities detected by MRI in patients of knee pain.
Methods: Fifty patient of knee pain were examined after taking permission from institutional ethics committee by using Siemens Avanto MR machine with a superconducting magnet and field strength of 1.5 tesla using dedicated knee coil (Flex), which were referred from department of Orthopedics & Rheumatology.
Results: In this present study 72% patients were males and 28% patients females and their ages ranging from (11-80) years. Knee pain was found common in age group 31-40 years. Menisci lesions (44%) were more common as compared to ligament lesions (14%) in patients of knee pain. Osteoarthritis was found in 40 % of patients of knee pain. Joint effusion and marrow edema was found with incidence of 74% and 62% respectively. 4% patients were suffering from intraarticular tumors.
Conclusions: Knee pain can occur at any stage of life due to various causative factors. MRI can demonstrate the exact nature and extent of bony as well as soft tissue abnormality. This has increase the use of MRI in evaluation of patients of knee pain.

Keywords: MRI, Knee pain, Menisci, Osteoarthritis

INTRODUCTION

Knee problems may be responsible for much of musculoskeletal disability in elderly persons. The prevalence of abnormalities increased with age, as might be expected. Knee pain is considered as most frequent symptom related to knee problems which brings patient to the hospital. Knee pain and related symptoms may come as a result of damage to one or more of the soft tissue structures that stabilize and cushion the knee joint, including the ligaments, muscles, tendons, and menisci or due to non-traumatic injury like infection, inflammation etc.[1] Presentation of knee pain in a middle-aged or older patient often leads to an x-ray of the knee but MRI is being used in clinical practice to facilitate diagnostic decisions. The potential for MRI to be more sensitive to earlier disease, detecting change, and the capacity of this technology to visualize joint structural changes beyond gross changes in bone and in the joint space, has resulted in great interest in the use of MRI for assessing diagnostic status, disease severity and monitoring progression.[2,3] MRI visualizes most components of the joint, including articular cartilage, menisci, intra-articular ligaments, synovium, bone marrow, subchondral cysts, and other periarticular and intra-articular lesions that are not detectable by radiography.[4] Various studies have reported structural changes in people with knee osteoarthritis by radiographic findings. Very few data are available regarding what structural changes are present in patients of knee pain and also this type of study was not

conducted in our institute. So, this study was planned to find out the prevalence of abnormalities detected by MRI in patients of knee pain which will guide the physician in making treatment strategies according to diagnosis.

METHODS

This prospective study was carried out for a period of six month after taking the permission from institutional ethics committee. A total of 50 patients referred to the department of Radio- diagnosis from department of Orthopedic and Rheumatology with complaints of knee pain were recruited. Patients' socio-demographic data, clinical history and physical examination findings were recorded after taking informed consent to correlate the findings. The patients of knee trauma and who had no complaint of knee pain were not included in this study.

Procedure:

MRI acquisition knees were imaged by using Siemens Avanto MR machine with a superconducting magnet and field strength of 1.5 tesla using dedicated knee coil (Flex).

Each examination consisted of the following: coronal intermediate-weighted (repetition time msec/echo time msec, 2200/20) and T2- weighted (2200/80) dual spin-echo images (number of signals acquired, two; section thickness, 5 mm; intersection gap, 0.5 mm; field of view, 160 mm; acquisition matrix, 205×256; and number of sections, 18), sagittal intermediate-weighted (2200/20) and T2- weighted 4 (2200/80) dual spin-echo images (number of signals acquired, two; section thickness, 4 mm; intersection gap, 0.4 mm; field of view, 160 mm; acquisition matrix, 205×256; and number of sections, 20), sagittal three dimensional T1- weighted spoiled gradient-echo frequency-selective fat suppressed images (46/2.5; one signal acquired; flip angle, 40°; section thickness, 3 mm; section overlap, 1.5 mm; no gap; field of view, 180 mm; acquisition matrix, 205×256; and number of sections, 80), and transverse intermediate weighted (2500/7.1) and T2-weighted (2500/40) turbo spin echo fat-suppressed images (number of signals acquired, two; section thickness, 2 mm; no gap; field of view, 180 mm; acquisition matrix, 205×256; and number of sections, 62). Total acquisition time, which included the initial survey sequence, was 30 minutes. Protocol of examination was in line with European society of musculoskeletal radiology (ESSR). It starts with the patient in supine position and slightly externally rotates the foot by about 10-15 degrees to stretch the anterior cruciate ligament. Pack some cushions around the knee to help it stay motion free. A small cushion under the ankle helps to keep the leg straight. Evaluation of the knee including the patello-femoral joint, medial and lateral compartments as well as related tendons and ligaments and the popliteal fossa is performed with a high resolution proton density sequence acquired in 3 planes: Axial, Sagittal and Coronal. Evaluation of bone marrow for contusion requires a T2 fat saturation sequence in either coronal or sagittal planes. If the patient has a suspicious mass then T1 fat saturation images are helping to determine if the mass is benign or malignant and better delineate its full extent. Obtained MRI images were diagnosed by an experienced musculoskeletal radiologist for the presence of ligament injury, tear, strain and laxity, as well as menisci degeneration and tear, joint effusion, subchondral and bone marrow edema, bony contusion, bursitis, baker cyst and tumor were noted in all patients.

Statistical analysis:

Data were expressed in percentages in comparison tables and graphs. Statistical analysis was performed using Microsoft Excel Software and the standard Statistical Package for the Social Sciences version 15 for windows.

RESULTS

Total 50 patients were recruited with in a study period of six month. MRI of knee was conducted in patients who were complaining knee pain. Of these 50 patients 36 (72%) were male and 14 (28%) were female, with male to female ratio of 2.6:1. Mean age of the patients was 42 years (range 11 to 80 years). They were classified into age groups and out of these groups 12 were found to be in age group between 31-40 years. In this age group 8 were male and 4 were female patients (Table 1).

Table 1: Distribution of patients according to age group and sex.

Age group	Males	Females	Number of patients (Total 50)	Percentage
<10	0	0	0	0
11-20	04	01	05	10
21-30	09	01	10	20
31-40	08	04	12	24
41-50	08	03	11	22
51-60	05	04	09	18
61-70	02	0	02	4
71-80	0	01	01	2

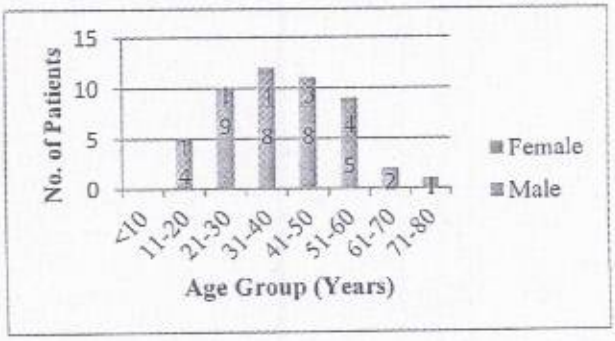

Figure 1: Demographic profile of patients including age & sex (n=50).

Table 2: Most common knee pathologies detected by MRI in patients of knee pain and their distribution with sex.

Knee pathologies	Male	Female	Total patients (50)
Joint effusion	25	12	37 (74%)
Bone marrow edema	22	9	31 (62%)
Meniscal lesions	15	7	22 (44%)
Osteoarthritis	10	10	20 (40%)
Ligament lesions	4	3	7 (14%)
Baker's cyst	4	2	6 (12%)
Ganglion cyst	4	1	5 (10%)
Subchondral edema	1	1	2 (4%)
Tumor	1	1	2 (4%)
Pateller Subluxation	1	1	2(4%)

Table 3: Types of meniscal lesion detected by MRI in patients of knee pain.

Meniscal degeneration (Grade 1)	7
Meniscal degeneration (Grade 2)	15
Total	22

Joint effusion was most frequently found knee pathology constituting 74% in patients of knee pain followed marrow edema (62%), meniscal lesion (44%), and osteoarthritis (40%). Osteomyelitis, simple bone cyst, bone infarct and chondomalacia patellae were least common constituting 2% incidence of each (Table 2). Meniscal injury (44%) was found more common in patients of knee pain as compared to ligament injury. Table 3 shows different grades of meniscal lesions in patients of knee pain.

DISCUSSION

MRI is a valuable tool in the evaluation and management of patients of knee pain and it has been established as an effective, noninvasive test for identifying different knee pathologies.[5] MRI affects the treatment of patients with knee problems because it shows entire lesion in multiple planes so that exact diagnosis and treatment can be planned. Studies have shown that surgery of the knee is less frequently performed after MRI than initially planned before MRI.[6,7]

In this study fifty patients of knee pain were evaluated by MRI. Knee pain was found to be common in males (72%) as compared to females. Similar results were reported in other studies too.[8,9] This could be because of more activities in young males during sports as compared to females and they are also are more prone to accidents. In our study most affected age group was 31-40 years. This supports the reasoning that it is more common in young adult. One study has reported more females as compared to male. We could not find exact reason for that.

Joint effusion was found to be most frequent associated lesion constituting 74%. In another study joint infusion was reported in 63.8%.[8] Higher percentage of joint effusion in our study and other study too could be due to more synovial reactions in patients of knee pain. Bone marrow edema was also found in 62% of patients of knee pain. This much high percentage of marrow edema in patients of knee pain may be due to non-specific finding which is simply fluid accumulation within the bone when there is any insult to bone. A recent systematic review reported that bone marrow lesions and effusion were associated with knee pain.[10]

Menisci lesions were found in 44% patients. Depending on the patient's age, a prevalence of meniscal lesion up to 36% has been reported.[11] In our study most of the menisci lesions was found in males. Similar results have reported by other studies too of higher incidence of menisci injuries in male.[12,13]

Grade I/II injury (signal changes) are common in our study because these are mostly occur with degeneration changes in knee joint and more common in 3rd and 4th decade[14] and in our study most of the patients were in age between 31-50. A meta-analysis based on 22 studies described an overall sensitivity of 88% and specificity of 94% for detecting meniscal lesions with different grades.[15] This would avoid unnecessary arthoscopic examination.[1]

Osteoarthritis was found in 40 % of patients of knee pain with equal prevalence in both male and female. Baker's cyst which is mostly present with osteoarthritis patient was found in 12% in patients. Similar incidence of baker's cyst has been reported by other study conducted by Nasir A.[9] In other studies incidence of osteoarthritis was found more in females and age above 50. The prevalence of osteoarthritis varies greatly depending on the definition used, age, sex and geographical area studied.[16,17]

Difference in our study could be due to more patients in age group 21-50 years. MRI is an excellent tool for diagnosis of intraarticular tumors which in our study shows 4% incidence. MRI is accurate, noninvasive technique for evaluating the structures of the knee, marrow space, synovium and periarticular soft tissue concerning the knee.[18,19]

To conclude, knee pain can occur at any stage of life due to various causative factors. Most of the patients in our study found to be males. MRI gives the noninvasive diagnosis to the patients for their appropriate treatment. This has increase the use of MRI in evaluation of patients of knee pain.

of Radio- diagnosis from department of Orthopaedic with complaints of knee pain. Other findings like demographic data, clinical history and physical examination were recorded after taking informed consent to correlate the findings. The patients of knee trauma and who had no complaint of knee pain were not included in this study.

Statistical analysis:

Data were expressed in percentages in comparison tables and graphs. Statistical analysis was performed using Microsoft Excel Software and the standard Statistical Package for the Social Sciences version 15 for windows.

RESULTS

Total 62 patients were recruited on the basis of inclusion ad exclusion criteria. MRI of knee was conducted in patients who were complaining knee pain. Of these 41 patients were males and 21 patients were females. Knee pain was found more common in 46-60 age group followed by 31-45 years age group and least in <15 years age group.

Joint effusion was most frequently found knee pathology constituting n=50 patients of knee pain followed marrow edema n=40, meniscal lesion n=33, osteoarthritis n=36 and Rheumatoid Arthritis n=12. Simple bone cyst, Ligament lesions, Bakers cyst were least common constituting (Table 1). Meniscal injury was found more common in patients of knee pain as compared to ligament injury. Table 2 shows different grades of meniscal lesions in patients of knee pain.

Table 1: Knee pathologies as detected by MRI in patients suffering from knee pain (n=62)

Knee Pathologies	Male	Female
Joint effusion	30	20
Bone marrow edema	32	8
Meniscal lesions	24	9
Osteoarthritis	20	16
Rheumatoid Arthritis	3	9
Ligament lesions	4	3
Baker's cyst	4	2
Ganglion cyst	4	0
Subchondral edema	1	1
Patellar Subluxation	1	0

Table 2: Meniscal lesion detected by MRI.

Meniscal degeneration	Number
Grade 1	8
Grade 2	15
Total	23

DISCUSSION

MRI plays an important in the assessment and the board of patients of knee torment and it has been set up as a successful, non-intrusive test for distinguishing distinctive knee pathologies.[5] MRI affects the treatment of patients with knee problems because it shows entire lesion in multiple planes so that exact diagnosis and treatment can be planned.

In this study n = 62 patients of knee pain were evaluated by MRI. Knee pain was found to be common in males as compared to females. These findings are in accordance with other studies too.[8,9] [6,7] This could be because of more activities in young males during sports as compared to females and they are also are more prone to accidents. In our study most affected age group was 46-60 years. This finding contradicts other studies showing high prominence in 30-45 age group.

Joint effusion was found to be most frequent associated lesion. In another study joint infusion was reported in 63.8 %.[5] Higher percentage of joint effusion in our study and other study too could be due to more synovial reactions in patients of knee pain. Bone marrow edema was also found in n=40 of patients of knee pain. This much high percentage of marrow edema in patients of knee pain may be due to non-specific finding which is simply fluid accumulation within the bone when there is any insult to bone. A recent systematic review reported that bone marrow lesions and effusion were associated with knee pain.[8]

In our study Menisci lesions were found in 52.8% patients. Depending on the patient's age, a prevalence of meniscal lesion up to 36% has been reported.[9] In our study most of the menisci lesions was found in males. Similar results have reported by other studies too of higher incidence of menisci injuries in male.[10,11]

As most of the patients in our study were found to be in between 31-50 Grade I/II injury (signal changes) are common in our study. A meta-analysis based on 22 studies described an overall sensitivity of 88% and specificity of 94% for detecting meniscal lesions with different grades.[12] This would avoid unnecessary arthoscopic examination.[1]

Cases of Osteoarthritis was found in 54.6 % of patients of knee pain with male and female affected equally. Baker's cyst which is mostly present with osteoarthritis patient was found in 9.6% in patients. Similar incidence of baker's cyst has been reported by other study conducted by Nasir A.[9] In other studies incidence of osteoarthritis was found more in females and age above 50. The prevalence of osteoarthritis varies greatly depending on the definition used, age, sex and geographical area studied.[13,14]

Our study differ from other studies as most of the patients were in age group 21-50 years. MRI is an excellent tool for diagnosis of intraarticular tumors which in our study shows 4% incidence. MRI is accurate, non-invasive technique for evaluating the structures of the knee, marrow space, synovium and periarticular soft tissue concerning the knee.[15,16]

CONCLUSION

It can be concluded from the findings of our study Knee pain can occur at any age due to various causative factors. MRI gives the non-invasive diagnosis to the patients for their appropriate treatment. Therefore, use of MRI in evaluation of patients of knee pain is increased now a days.

INTRODUCTION

A normal pregnancy should be happened between 38 and 42 weeks. The delivery of a single baby, with foetal weight of 2.5 kg or more and with no maternal complication is considered as normal pregnancy.[1] Other factors like biochemical test results, evaluation of foetal growth, risk assessment of various foetal anomalies, expanded maternal serum biomarkers, gestational age plays an important role and help the obstetrician to take proper measures that would optimize outcome of foetal.[2] There are major antenatal implications of using ultrasonography. It provides a safe and non-invasive means for the evaluation of the placenta whose normal and abnormal size, appearance and growth pattern can be explained. The placenta is a foetal organ. It provides the physiological link between a pregnant woman and the fetus with important metabolic, endocrine and immunologic functions. Moreover, it is also responsible for nutrition, respiration and excretion for the fetus. As a barrier, it has a role in protecting the fetus from harmful agents.[3] Placental size is a manifestation of health and size of the fetus. The placenta grows from the chorionic villi at the implantation site at about the fifth week of gestation and by the ninth or tenth week, it is clearly visible at sonography as diffuse granular echo texture.[4,5] Scientifically, it would define as the fusion of fetal organs to maternal tissue for the purpose of physiologic exchange. It is usually 2-4 cm thick and weighs around 600 grams.[6] With the new advances in grey scale and Doppler sonography, it is possible to study the placental sonographic appearance and its relationship to uteroplacental blood flow measurement and intrauterine growth. Accurate assessment of gestational age (GA) is very important in assessing the growth of fetus and to plan for delivery. Placenta is a source of nutrition for the developing fetus. It can throw light on its health and growth status also. Studies have revealed that

during 17-20 weeks, changes in placenta correlate well with the development of the fetus and can predict fetal abnormality. Currently the most effective way to date pregnancy is by the use of ultrasound parameters. Numerous sonographically derived fetal parameters are used to date the pregnancy. According to Campbell S, placental parameters are useful in assessing GA and intra uterine growth retardation that needs early intervention. For estimating gestational age, measurement of placental thickness (PT) can also be used as a new additional parameter. Obstetric sonography provides the accurate determination of gestational age. It is the most useful information. In estimating GA, growing evidences on the prediction of placental thickness are directing the obstetricians to measure PT as a routine in pregnant woman.[7-12]

METHODS

Study Population: - In our study we includes 200 normal antenatal subjects of gestational age ranging from 11 weeks to 40.

Study Area: - This study conducted in the Department of Radiology.

Data collection: - The transabdominal sonography was performed on each subject using Philips Envisor equipment, which has a multifrequency convex transducer with frequency range of 2 to 5MHz. Thickness of placenta was measured from the echogenic chorionic plate to placental myometrial interphase (excluding myometrium and sub placental veins). All these measurements are taken when uterine myometrium is in relaxed phase. Sonologically site of umbilical cord insertion was identified as a 'V' shaped hypo echoic area close to the chorionic plate, where placental thickness was maximum. Calculation of gestational age in 1st trimester was done by measuring CRL (crown-rump length) using had lock tables and for 2nd & 3rd trimesters composite of fetal measurements like biparietal diameter, circumference of head and abdomen taken at appropriate levels and femur length are used.

Data analysis:-Data were analysed by using Microsoft excel.

RESULTS

In our study we were included total 200 cases. Among all cases 146 cases were belongs to 20-25 age group followed by 26-30 (28),<20(16) & >30(10). We observed placental position, out of 200 cases 66 cases of fundal anterior, 58 cases of fundal posterior,24 cases of anterior wall,26 cases of posterior wall & 26 cases of lateral wall position of placenta. This result revealed that placental thickness increases with each week of gestation from 11.51mm at 11 weeks to 37.13mm at 40 weeks of gestational age as given in last.

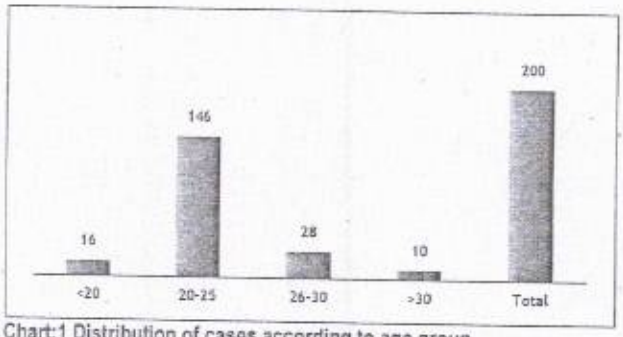

Chart:1 Distribution of cases according to age group

Table 1: Distribution of cases according to Placental position

Placental position	frequency
Fundal anterior	66
Fundal posterior	58
Anterior wall	24
Posterior wall	26
Lateral wall	26
Total	200

Table 2: Distribution of cases according to mean placental in relation of gestation age

Gestation age in weeks	No. of cases	Mean placental thickness
11	4	11.51
12	2	11.86
13	6	12.62
14	4	13.53

36	22	35.46
37	8	36.75
38	6	36.23
39	2	37
40	2	37.13

DISCUSSION

Previously, placenta was evaluated to determine its position or to know any premature separation is present or not. Due to this its role in management of pregnancy is very limited. But now days, with the help of advanced ultrasound equipment and more detailed examination of placenta, it is possible to understand the possible morphological changes

as the placenta matures from first trimester itself. Changes in placental thickness are an indication of normal growth of fetoplacental unit which is measurable on sonography. Altéred placental thickness has been related with several fetal and maternal pathological conditions. Measurement of placental thickness has an important role in screening of pregnancy related complications. Placental thickness must be required for each week of gestation. The abnormalities of fetus can be observed by calculating the placental thickness, as thickness of placenta is changed due to pathological processes.[13] Recognition of posteriorly located placentas is done by acquiring images, where fetal accosting shadowing is least and for anteriorly placed placentas correct positioning of transducer and proper adjustment of gain settings will decrease the near field and reverberation artifacts. Accuracy of placental measurements depends on detailed acquisition and interpretation of images. Error rate can be minimized by taking accurate measurements. For example, imaging obliquely through the placenta leads to images showing increased placental thickening which is incorrect. To reduce these measurement errors, it is necessary to perform the examinations by using the same equipment and also by the same examiner.

It is evident from the above study that sonographic measurement of placental thickness in singleton pregnancies can be used as an additional tool in the assessment of gestational age as its linear correlation with gestational age. An abnormal placental thickness for the respective gestational age should raise the suspicion of any underlying pathological process which may affect the pregnancy outcome. This early identification of abnormalities may help the obstetrician to consider specific antenatal care.

CONCLUSION

It can be concluded that antenatal ultrasound examinations should include measurement of placental thickness, because it helps in quantifying intrauterine environmental adequacy and fetal well-being.

An Analytical Study on Prevalence of Knee joint abnormalities assessed by MRI- A Hospital Based Study

Lalit Bhandari[1], Rahul Mangal[2]*

[1]Associate Professor, Department of Radio diagnosis, AIMS & RC, Rajsamand.
[2]Assistant Professor, Department of Radio diagnosis, AIMS & RC, Rajsamand.

ABSTRACT

Background: *In order to treat the patients suffering from knee joint ailments, diagnosis has plays an essential role for treatment and to avoid unnecessary surgery. MRI is a non-invasive procedure in evaluation of knee joint. So this study was planned find out the prevalence of abnormalities detected by MRI in patients of knee pain.*

Methods: *This prospective study was carried out on n= 62 patients of knee pain. Patients were examined after taking permission from institutional ethics committee by using Siemens Avanto MR Machine with a superconducting magnet and field strength of 1.5 tesla using dedicated knee coil (Flex), which were referred from department of Orthopaedics.*

Results: *In this present study 41 patients were males and 21 patients females and their ages ranging from (20-65) years. Knee pain was found common in age group 46-60 years age group. Joint effusion n=50 were more common followed by Edema n=40, Menisci lesions n=33 were more common as compared to ligament lesions n=7 in patients of knee pain. Osteoarthritis was found in 54.6 % of patients of knee pain.*

Conclusion: *Knee pain can occur at any stage of life due to various causative factors. MRI can demonstrate the exact nature and extent of bony as well as soft tissue abnormality. This has increase the use of MRI in evaluation of patients of knee pain.*

Keywords: *MRI, Knee pain, Menisci, Osteoarthritis*

INTRODUCTION

Knee pain is considered as most frequent symptom related to knee problems which brings most of the patient to the hospital. Knee pain and related symptoms may come as a result of damage to one or more of the soft tissue structures that stabilize and cushion the knee joint, including the ligaments, muscles, tendons, and menisci or due to non-traumatic injury like infection, inflammation etc.[1] Presentation of knee pain in a middle-aged or older patient often leads to an x-ray of the knee but MRI is being used in clinical practice to facilitate diagnostic decisions. The potential for MRI to be more sensitive to earlier disease, detecting change, and the capacity of this technology to visualize joint structural changes beyond gross changes in bone and in the joint space, has resulted in great interest in the use of MRI for assessing diagnostic status, disease severity and monitoring progression.[2,3] MRI visualizes most components of the joint, including articular cartilage, menisci, intra-articular ligaments, synovium, bone marrow, subchondral cysts, and other periarticular and intra-articular lesions that are not detectable by radiography.[4] Various studies have reported structural changes in people with knee osteoarthritis by radiographic findings. Very few data are available regarding what structural changes are present in patients of knee pain and also this type of study was not conducted in our institute. So, this study was planned to find out the prevalence of abnormalities detected by MRI in patients of knee pain which will guide the physician in making treatment strategies according to diagnosis.

METHODS

This prospective study was carried out on patients of knee pain attending Orthopaedic. Study was commenced after written informed consent taken from all the patients and with the permission from institutional ethics committee. A total of 62 patients referred to the department of Radio- diagnosis from department of Orthopaedic with complaints of knee pain were recruited. Patients' socio-demographic data, clinical history and physical examination findings were recorded after taking informed consent to correlate the findings. The patients of knee trauma and who had no complaint of knee pain were not included in this study.

Statistical analysis:

Data were expressed in percentages in comparison tables and graphs. Statistical analysis was performed using Microsoft Excel Software and the standard Statistical Package for the Social Sciences version 15 for windows.

RESULTS

Total 62 patients were recruited on the basis of inclusion ad exclusion criteria. MRI of knee was conducted in patients who were complaining knee pain. Of these 41 patients were males and 21 patients were females. Knee pain was found more common in 46-60 age group followed by 31-45 years age group and least in <15 years age group.

Joint effusion was most frequently found knee pathology constituting n=50 patients of knee pain followed marrow edema n=40, meniscal lesion n=33, osteoarthritis n=36 and Rheumatoid Arthritis n=12. Simple bone cyst, Ligament lesions, Bakers cyst were least common constituting (Table 1). Meniscal injury was found more common in patients of knee pain as compared to ligament injury. Table 2 shows different grades of meniscal lesions in patients of knee pain.

Table 1: Clinical Presentation of knee pathologies detected by MRI in patients of knee pain (n=62)

Knee Pathologies	Male	Female
Joint effusion	30	20
Bone marrow edema	32	8
Meniscal lesions	24	9
Osteoarthritis	20	16
Rheumatoid Arthritis	3	9
Ligament lesions	4	3
Baker's cyst	4	2
Ganglion cyst	4	0
Subchondral edema	1	1
Patellar Subluxation	1	0

Table 2: Types of meniscal lesion detected by MRI in patients of knee pain.

Meniscal degeneration	Number
Grade 1	8
Grade 2	15
Total	23

DISCUSSION

MRI is a valuable tool in the evaluation and management of patients of knee pain and it has been established as an effective, non-invasive test for identifying different knee pathologies.5 MRI affects the treatment of patients with knee problems because it shows entire lesion in multiple planes so that exact diagnosis and treatment can be planned. Studies have shown that surgery of the knee is less frequently performed after MRI than initially planned before MRI.[6,7]

In this study fifty patients of knee pain were evaluated by MRI. Knee pain was found to be common in males as compared to females. These findings are in accordance with other studies too.[8,9] This could be because of more activities in young males during sports as compared to females and they are also are more prone to accidents. In our study most affected age group was 46-60 years. This finding contradicts other studies showing high prominence in 30-45 age group.

Joint effusion was found to be most frequent associated lesion. In another study joint infusion was reported in 63.8 %.[8] Higher percentage of joint effusion in our study and other study too could be due to more synovial reactions in patients of knee pain. Bone marrow edema was also found in n=40 of patients of knee pain. This much high percentage of marrow edema in patients of knee pain may be due to non-specific finding which is simply fluid accumulation within the bone when there is any insult to bone. A recent systematic review reported that bone marrow lesions and effusion were associated with knee pain.[10]

Menisci lesions were found in 52.8% patients. Depending on the patient's age, a prevalence of meniscal lesion up to 36% has been reported.[11] In our study most of the menisci lesions was found in males. Similar results have reported by other studies too of higher incidence of menisci injuries in male.[12,13]

Grade I/II injury (signal changes) are common in our study because these are mostly occur with degeneration changes in knee joint and more common in 3rd and 4th decade14 and in our study most of the patients were in age between 31-50. A meta-analysis based on 22 studies described an overall sensitivity of 88% and specificity of 94% for detecting meniscal lesions with different grades.[15] This would avoid unnecessary arthoscopic examination.[1]

Osteoarthritis was found in 54.6 % of patients of knee pain with equal prevalence in both male and female. Baker's cyst which is mostly present with osteoarthritis patient was found in 9.6% in patients. Similar incidence of baker's cyst has been reported by other study conducted by Nasir A.[9] In other studies incidence of osteoarthritis was found more in females and age above 50. The prevalence of osteoarthritis varies greatly depending on the definition used, age, sex and geographical area studied.[16,17]

Difference in our study could be due to more patients in age group 21-50 years. MRI is an excellent tool for diagnosis of intraarticular tumors which in our study shows 4% incidence. MRI is accurate, non-invasive technique for evaluating the structures of the knee, marrow space, synovium and periarticular soft tissue concerning the knee.[18,19]

To conclude, knee pain can occur at any stage of life due to various causative factors. Most of the patients in our study found to be males. MRI gives the non-invasive diagnosis to the patients for their appropriate treatment. This has increase the use of MRI in evaluation of patients of knee pain.

CONCLUSION

Knee pain can occur at any stage of life due to various causative factors. Most of the patients in our study found to be males. MRI gives the non-invasive diagnosis to the patients for their appropriate treatment. This has increase the use of MRI in evaluation of patients of knee pain.

A B S T R A C T

Introduction: High definition computed tomography is a variation of routine Tomography. It gives a clean visual window of the temporal bone and enables minute structural of anatomy and physiology of temporal bone. The present study was conducted with the aim to assess the role of high resolution computed tomography in diseases of temporal bone and correlating the HRCT image findings with the pathological findings.

Material and Methods: The study was conducted amongst 100 patients who underwent HRCT temporal bone and relevant statistics are drawn from these cases. After local examination, clinical evaluation and consent, C.T scan was performed. Follow up of patients was done for confirmation with operative and/or histopathological findings whenever possible. The findings were noted in a tabulated form and a differential diagnosis were established.

Results: 61 cases were of infective etiology, out of which 16 were of chronic otomastolditis, 4 were of chronic mastoiditis, 38 were of chronic otomastoiditis with cholesteatomas formation and 3 were of otitis externa. Out of 100 cases, 6 were of congenital pathology, 22 were of traumatic, 1 was of dysplasia, 4 were of neoplastic and 6 were normal. Among patients with structures involved due to cholesteatomas, facial nerve was involved in 26 cases, ossicles in 23 cases, tegmen tympaniin 19 cases, sinus plate in 21 cases, intracranial structures in 10 cases and inner ear in 12 cases.

Conclusion: Amongst patients with trauma to temporal bone, HRCT precisely predicts the fracture lines, disruptions of the ossicles and injury to facial nerve. Therefore, it enables the management of most of trauma subjects. A HRCT helps to explain the possible outcomes to the patient as well as assist the otologist to predict disease during the surgery

Keywords: High Resolution Computed Tomography, Mastoid, Temporal Bone, Radiology

INTRODUCTION

Earlier, in majority of the pathologies of temporal bone, diagnosis were established based on clinical evaluation alone. However, with elevation in the incidence of infective diseases of the ear, it was recommended that the present approach to prevent and treat the situation was not adequate. So, primarily in complicated and recurrent situations, imaging carries a crucial role, as imaging results may fundamentally affect the treatment.[1]

High definition computed tomography is a alteration of routine CT. It gives a direct visual window of the temporal bone and enables to visualize minute structural information of both anatomy and physiology of temporal bone. It has the advantage of providing outstanding topographic observations, devoid of superimposition from structures. It enables an accurate evaluation of pathology before surgical exploration with respect to the location, degree and complications of the disorder.[2] In the developing nations like ours, this modality is easily available and inexpensive to the subjects. So, there are chances that the radiologist is likely experience greater frequency of HRCT studies and the knowledge of temporal bone on HRCT will be tremendously beneficial in achieving an accurate diagnosis.[3] The present study was conducted with the aim to evaluate role of this imaging modality in temporal bone disorders and correlating the hrct image based results with both operative and pathological outcomes.

MATERIAL AND METHODS

It was a prospective study done in department of Radiodiagnosis and Imaging in Ananta Institute of Medical Science and Research Center Rajsamand, Rajasthan in collaboration with the deparment of otorhinolaryngology amongst patients with suspected temporal bone disorder. It was conducted for a period of 8 months from June 2018 to February 2019. The study is carried out on 100 patients who underwent HRCT temporal bone and relevant statistics are drawn from these cases. The subjects included were both male and females, in the age group of 1year to 60 year. The subjects referred from OPD or IPD with chief complaints and clinical outcomes relating to temporal bone disorder for examination by high resolution CT were enrolled in the study. Inclusion

criteria was suspected unsafe chronic serous otitis media (CSOM), known or suspected deformities of inner, middle or external ear, suspected temporal bone fracture, suspected tumors of temporal bone evaluation of congenitally deaf child and evaluation of tinnitus or vertigo. Patients aged <1 and >70 years, patient requiring contrast study but were clinically unfit for contrast workup, pregnant women and patients who cannot give a valid consent were excluded from the study. Relevant clinical evaluation was carried out at the presentation. X-ray of mastoid was also reviewed if taken. After relevant examination and informed consent, C.T scan was performed as follows; The examination of patients was done using Brilliance 64 Philips CT scanner and after eliminating all the artefacts from the scanning area. It was done with 0.625 mm thick sections at slice gap of 0.625mm. 140 kV and 300 mAs were used as voltage and current. The cycle duration was 2 seconds. Scanning was done in axial plane. Scan plane was kept parallel to infraorbitomeatal line to prevent radiation to lens. Scanning was done so as to include temporal bone anteroposteriorly on both sides Entire petrous temporal bone was scanned anteroposteriorly in accordance with the topogram. Intravenous contrast was used only in cases that needed assessment of vascular lesions, soft tissue changes and breakdown of blood brain barrier, suspected either clinically or on plain scan. The images were reconstructed and visualized in special bone algorithm. Multiplanar reconstructions were done whenever required in sagittal and coronal planes. Documentation was done on 14 x 17" films. Images were magnified and recognized on separate sheets to enable comparison.

Follow up of patients was done for confirmation with operative and/or histopathological findings whenever possible. All the data thus obtained was recorded in a tabulated form and analysed.

RESULTS

The present study found that among 100 cases of temporal bone diseases (table 1), 61 cases were of infective etiology, out of which 16 were of chronic otomastoiditis, 4 were of

chronic mastoiditis, 38 were of chronic otomastoiditis with cholesteatomas formation and 3 were of otitis externa. Out of 100 cases, 6 were of congenital pathology, 22 were of traumatic, 1 was of dysplasia, 4 were of neoplastic and 6 were normal. Among congenital etiology 1 was of ossicular abnormalities, 1 was of facial nerve involvement, 2 were of microrotia, 1 was of inner ear dysplasia and 1 was of congenital cholesteatoma. Among 22 cases of traumatic etiology, 6 cases were of transverse type, 11 were of longitudinal and 5 were of mixed type.

Table 2 shows structures involved due to cholesteatomas, facial nerve was involved in 26 cases, ossicles in 23 cases, tegmen tympaniin 19 cases, sinus plate in 21 cases, intracranial structures in 10 cases and inner ear in 12 cases.

Among trauma cases of temporal bone, HRCT showed hemotympanum involvement in 11 cases, facial nerve involvement in 6 cases, labyrinthine involvementin 2 cases, ossicular involvement in 1 case and intracranial involvement in 5 cases (table 3).

DISCUSSION

The present study found that among 100 cases of temporal bone diseases, 61 cases were of infective etiology, out of which 16 were of chronic otomastoiditis, 4 were of chronic mastoiditis, 38 were of chronic otomastoiditis with cholesteatomas formation and 3 were of otitis externa. Figure 1 shows image of cholesteatoma by high resolution computed tomography The role of X-rays in evaluation of a cholesteatoma is very less. Minute alterations like erosion of ossicules, participation of concealed areas and destruction of facial canal and the LSSC are tremendously difficult to evaluate with X-ray.[4] The aptitude of high-resolution CT to portray the station of structure of temporal bone presents a major advancement in defining pathology before surgical exploration in patients with cholesteatoma.[5] The diagnosis of cholesteatoma is normally made on otological findings in situations where diagnosis is not clear. HRCT temporal bone may show a soft-tissue mass with distinguishing displacement of ossicles and erosion of bone. Cholesteatoma in hidden areas could be revealed by radiological evaluation even if it is not visualized clinically. High-resolution computed tomography scanning of the temporal bone is the imaging modalities of choice to evaluate the extension of cholesteatoma before surgery.[6] Erosion occurs chiefly due to the substances released by mononuclear cells of inflammation and osteoclasts. An expanding cholesteatoma can erode the antrum and mastoid spaces, even additional structures like the bony facial canal, tegmen and the lateral semi-circular canal[4] Out of 26 patients with facial canal involvement that were included in current study, 19 were confirmed by surgery. The results of the present study were in agreement with the study by Fuse T et al[7] who found that in 75% HRCT image based evaluation of facial nerve canal erosion coincided with surgical results. There were 97% subjects HRCT results of semicircular canal fistula concurred with surgical results. As per the study by Thukral CL et al[1] amongst 50 patients with clinically suspected temporal bone or ear pathologies found that the imaging results related to the surgical findings wherever possible. HRCT delivers a good sensitivity of approximately 80.65% in the documentation of variations to the ossicular chain regardless of the presence of soft tissue. Sreedhar S et al[4] compared findings of HRCT scan of 25 patients clinically diagnosed to have CSOM attico-antral type of disease with the intraoperative findings. HRCT scan was found to have a high sensitivity for identification of the disease at most of the sites within the temporal bone except for the sinus tympani and the stapes region. Fritz P et al[8] carried a radiological evaluation of temporal bone diseases and reported that high-resolution CT allows for a clearer diagnosis amongst 80% of cases, conventional radiology enables the same amongst 63%; which is 1.6-times more than the bone information recorded by high-resolution CT, clearly indicating superior features in imaging of cholesteatomas and inflammatory processes and for evaluation of bony destruction. High-resolution CT is the most delicate technique for imaging and classification of the fractures of temporal bone, like labyrinthine injury and ossicular chain damages.

Typical complications occurring from cholesteatoma like ossicular destruction, facial nerve canal, attical wall damage etc can be clearly demonstrated with this technique. As per the study by Koster O et al[9] it was found that the degree of the soft tissue diseased process is clearly shown; however, the differentiation from associated inflammatory alterations is not possible.

In the present study, among cases of congenital etiology, 1 case was of ossicular abnormalities, 1 was of facial nerve involvement, 2 were of microrotia (figure 2), 1 was of inner ear dysplasia and 1 was of congenital cholesteatoma. These findings are in agreement with the findings of Meyer TE et al[10] amongst 184 cases of congenital auricular dysplasia concluded that the extent of the auricular irregularities resembled to the severity of vicissitudes in the external auditory canal.

As regards trauma mechanisms and main complications of each type of temporal fracture, they may be summarized as follows: a) longitudinal fractures generally occur in cases of temporoparietal trauma, commonly affecting the extra labyrinthine segment, and presenting as main complications ossicular lesion and hemotympanum; b) on the other hand,

ISSN (Online): 2565-4810; (Print): 2565-4802 | ICV 2017: 69.52 |

transverse fractures generally occur in cases of frontal/ occipital traumas, with translabyrinthine involvement, whose main complication is facial nerve weakness.[11] In the present study, among 22 cases of traumatic etiology, 6 cases were of transverse type, 11 were of longitudinal and 5 were of mixed type. HRCT showed Hemotympanum involvement in 11 cases, Facial nerve involvement in 6 cases, Labyrinthine involvementin 2 cases, Ossicular involvement in 1 case and Intracranial involvement in 5 cases. Twemlow S[12] amongst 205 cases of temporal bone and found that it can precisely diagnose middle ear disease. He also contingent that it delivers efficient usage of resources with low risk to the subjects. The improved contrast and soft tissue definition possible with HRCT produced excellent images of soft tissue in air spaces. Therefore, HRCT seems to be the diagnostic modality of high-quality for cholesteatomas and different soft tissue lesions in ear. HRCT also clearly demonstrates various complications of cholesteatomas and provides a detailed preview of the temporal bone prior to surgery thus enabling the surgeon to operate without any surprises.

CONCLUSION

In patients with temporal bone trauma, HRCT accurately evaluates the fracture lines, ossicular disruptions and facial nerve canal injury. Hence it determines the management of trauma patients. A HRCT helps to explain the possible outcomes to the patient as well as assist the otologist to predict disease during the surgery

ABSTRACT

Background: Evaluating patients who have sustained blunt abdominal trauma (BAT) remains one of the most challenging and resource-intensive aspects of acute trauma care. Missed intra-abdominal injuries continue to cause preventable deaths. **Aims & Objective:** To analyse spectrum of MDCT findings in cases of blunt abdominal trauma presenting to the emergency radiology department. **Materials and Methods:** 92 cases of blunt abdominal injury admitted in during the period of June 2018 to Dec 2018 were included in the study after taking written informed consent. All these patients were thoroughly investigated. CT Scan was done for all hemodynamically stable patients. Recorded data included age, sex, type of injuries and scan results. Organ injuries were graded using the OIS (Organ Injury Scale) guidelines. **Results:** The study comprised of 92 patients having blunt abdominal injury. Majority of the patients were in the age group of 21-40 years. Most common organ injured was liver (34.78%), kidney (15.22%), spleen (10.87%), bowel injuries (8.70%) and pancreatic injuries (6.52%). **Conclusion:** In this study CT scan was highly useful in diagnosis of blunt abdominal trauma. OIS (organ injury scale) grading, quantification of hemoperitoneum and anatomical site of organ injury predict the management protocols in the majority of our patients.

KEYWORDS: Blunt Abdominal Trauma; CT Scan; liver; Hemoperitoneum.

INTRODUCTION

The care of trauma patients is demanding and requires speed and efficiency. Blunt Abdominal Trauma usually results from motor vehicle collisions, assaults, recreational accidents, or falls. Men tend to be affected slightly more often than women. Evaluating patients who have sustained blunt abdominal trauma remains one of the most challenging and resource-intensive aspects of acute trauma care. Missed intra-abdominal injuries continue to cause preventable deaths. Neurological impairment due to the traumatic event itself or to concomitant factors such as intoxication markedly limits the usefulness of the clinical examination.

The most commonly injured organs are the liver, kidney, spleen, retroperitoneum, small bowel, bladder, colon, diaphragm, and pancreas. Computed tomography (CT) scan remains the criterion standard for the detection of solid organ injuries. CT scan of the abdomen can reveal other associated injuries, notably vertebral and pelvic fractures and injuries in the thoracic cavity. CT scans, unlike diagnostic peritoneal lavage (DPL) or Focused Assessment with Sonography for Trauma (FAST) examinations, have the capability to determine the source of haemorrhage. Over the last decade, Computed Tomography (CT) has gained widespread clinical acceptance in evaluation of haemodynamically stable patients with blunt abdominal trauma. CT not only allows comprehensive evaluation of presence and extent of injuries to solid organ, retroperitonium, bowel, mesentery and associated haemorrhage but also allows surgeons to reach vital decisions regarding the need of surgery. Accurate diagnosis with CT has played a key role in the increasing trend towards non-operative management of many visceral injuries.

Moreover, routine use of CT has substantially reduced the number of additional radiographic studies as well as the need of Diagnostic peritoneal lavage.[1] CT also plays major role in follow up of the patients with blunt abdominal trauma, determining injury resolution or progression and development of associated complications.[2] The advent of Multi Detector Computed Tomography (MDCT) is a major advancement in evaluation of patients of abdominal trauma by offering decreased scanning time, increased resolution owing to

thinner collimation and reduced partial volume and motion artifacts. MDCT scans rapidly during vascular, parenchymal, excretory phases with optimal contrast enhancement. The volumetric data acquired can be used to obtain high resolution multiplanar reformations (MPR), maximum intensity projection (MIP) and three-dimensional (3-D) reconstruction images. These views help in displaying complex injuries and also increasing diagnostic capability, accuracy and confidence of the radiologist immensely. MDCT has major role on number of patients with solid organ injury and non-operative management.[3]

AIM

To analyse spectrum of MDCT findings in cases of blunt abdominal trauma presenting to the emergency radiology department.

MATERIALS AND METHODS

The prospective study was conducted in Ananta institute of medical science and research centre Udaipur Rajasthan from june 2018 to Dec 2018. Patients reporting to the emergency, with suspected abdominal injuries and evaluated for the same by CT abdomen and pelvis were included in the study.

Inclusion criteria

- Patients with clinically suspected abdominal trauma with uncertain abdominal signs reporting to casualty department.
- Patients with pelvic fractures.
- Hemodynamically unstable patients who later become stable following fluid/blood replacement and other resuscitative measures were also taken up.

Exclusion criteria

- Patients who were haemodynamically unstable and were directly taken up for surgery.
- Patients with penetrating trauma.
- Cases where the intra venous contrast was contraindicated.

Out of 100 patients 92 full filled the inclusion criteria and rest of the 8 patients were excluded from the study.

All the eligible 92 subjects were included in the study, hence no sampling was done. All the patients included in the study underwent CT imaging using 64 slice multidetector (brilliance 64 philips). CT Images were acquired in arterial phase (25 - 30 secs), Porto-venous phase (60-70 secs) following intravenous contrast administration of 80 - 100 ml. Delayed excretory images were acquired at 10 - 15 minutes for evaluation of the urinary tract. Descriptive analysis of various abdominal injuries was presented as frequencies and percentages.

OBSERVATIONS AND RESULTS

Ninety-two (92) hemodynamically stable patients sustaining blunt abdominal trauma referred form the casualty were included in the study. Each patient underwent contrast enhanced MDCT examination of the whole abdomen. The data for this prospective study was collected and was subjected for analysis and clinical correlation. The study group comprised of patients ranging from 10 to 70 years of age. Majority of the patients were in the age group of 21 to 40 years accounting for 54% (50/92) of cases. The mean age in the study was 33.13 ± 14.48 years. Out of 92 patients 74 were males and remaining 18 were females. The male to female ratio in the study group was around 4:1.Pattern of different organ injuries on MDCT is summarized in Table 1.

Hepatic Injury

The liver was the most commonly injured organ accounting for 34.78% (32/92) of injuries. More than 50% of hepatic injuries were grade II and grade III injuries. Hepatic injuries were associated with; injuries to other abdominal organs in 18.75% (6/32) of cases, rib fractures in 50% (16/32) patients more commonly on right side and injury to lungs either in form of lung contusion, pneumothorax, atelectasis or pleural effusion in 31.25% (10/32) patients (Table 2).

Splenic Injury

The spleen was the third most commonly injured organ after liver and kidney accounting for around 10.8% (10/92) of injuries. Grade II injuries constituted around 80 % of splenic injuries.

The splenic injuries were associated with injuries to other intra-abdominal organs in 40% (4/10) of cases, injuries to lungs either in form of lung contusion, atelectasis, or pleural effusion in 20% (2/10) of patients. None of the case was associated with rib fracture (Table 3).

Renal Injury

The kidneys were second most commonly injured solid organ 15.2% (14/92). Cases with right renal injury occurred in 57% (8/14) and left renal injury in remaining 43% (6/14) of patients with renal trauma. Renal injuries were associated with injuries to other intra-abdominal organs in 57% (8/14) of cases, most commonly liver in cases of right renal injury and spleen in cases of left renal injury. Grade III and grade IV injury was seen in 43% and 57% of cases respectively. There was no case with grade I and II injury (Table 4 and 5).

Pancreatic Injury

The pancreatic injuries were observed in around 6.52% (6/92) cases. Sixty six (66%) percent of pancreatic injuries were grade II injuries and 33.3% were grade I. The pancreatic injuries were associated with injuries to; liver in 66.6% (4/6) of cases, injuries to kidneys in 66.6% (4/6) of cases involving right and left kidney

separately and injuries to spleen in 33.3% (2/6) of cases (Table 6).

Bowel and mesenteric injuries

Bowel and mesenteric injuries were seen in around 13.04% (12/92) of cases. Four (8/12) patients had bowel injury, whereas only two (4/12) patients had mesenteric injury. The mesenteric hematomas were associated with hemoperitoneum without solid organ injuries in 100% (4/4) patients. One case was operated and was found to have mesenteric injury preoperatively, which was not detected by MDCT (Table 7).

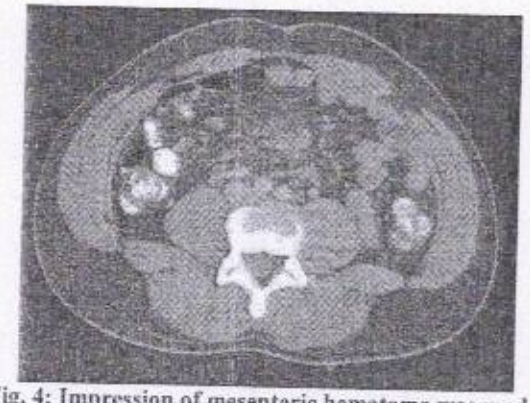

Fig. 4: Impression of mesenteric hematoma was made on basis of MDCT findings.

DISCUSSION

The present study was undertaken to evaluate the role of Multi detector computed tomography (MDCT) in management of clinically stable patients with blunt abdominal trauma by comparing management plan prior to MDCT scan with management plan after MDCT scan and to correlate CT findings with surgical findings in operated cases of blunt abdominal trauma and clinical outcome in conservatively managed cases. In the present study, comprising (92) clinically stable patients with blunt abdominal trauma, more than 54% of the patients were in the age group of 21 to 40 years. The male tonfemale ratio was 4:1. The most common mode of injury was road traffic accident (69.5%) followed by fall from height (17.3%). Bony injuries (including ribs, pelvis and spine) were the most common associated injury (80%) followed by chest injury (atelectasis, pleural effusion, contusion, and pneumothorax) which was seen in 23.9% of cases.

In a study by *Mohapatra et al.*,[4] blunt abdominal trauma accounted for 44% of all abdominal injuries. More than three fourth (3/4th) of the victims were in the first four decades of their lives. Male-Female ratio was 7:1. Road traffic accidents (RTA) were the most common etiology (62%) mostly involving pedestrians or two wheeler riders (combined, 47%). Chest injury was the most common associated extra-abdominal injury (26%) followed by head injury and other bony injuries (21% each).

In the present prospective study, a statistically significant difference (p=0.052) was found between the management plan decided before and after MDCT scan (guided by CT scan findings). The use of MDCT in initial triage of patients with blunt abdominal trauma results in decrease in number of unnecessary laparotomies and helps guiding management plan in virtually every patient with high success rate. In a study by *Wing and associates*[5] evaluating clinical impact of CT for blunt abdominal trauma, it was concluded that the use of computed tomography (CT) had a tremendous impact on the evaluation and management of blunt abdominal trauma. It is non-invasive, easy to perform, and has been shown to be highly sensitive (100%), specific (96.8%), and accurate (97.6%). The use of CT has helped decrease the total number of laparotomies performed for abdominal trauma as well as the number of negative and non-therapeutic laparotomies. In a retrospective study performed by *Udekwu et al.*,[6] to evaluate the use of computed tomography in the initial evaluation of hemodynamically stable blunt trauma patients, the sensitivity of CT for patients with visceral injury was 92.4%, specificity was 99.5%, and overall accuracy was 97.6%. False negative scans occurred in 1.9% of patients, with no deaths or major complications attributable to delay in diagnosis. Non-operative management was possible in 72% of patients with solid organ injuries. In the present study, among (68) patients with solid organ injuries, 76.4% (52/68) were managed conservatively All patients of grade I injury were managed conservatively.

Out of 20 patients with grade II injuries 70% (14/20) were managed conservatively. All patients with grade III injuries were managed conservatively. Out of 18 patients with grade IV injuries 55.5% (10/18) were managed conservatively. 2 patients with grade V injury were operated. *Hackam et al.*,[7] and *Shapiro et al*[8] in their studies regarding correlation between solid organ injury grading and management plan concluded that although useful for epidemiologic studies, CT grading of liver and spleen injuries based on morphology of wounds does not reliably predict the specific outcome in individual cases. In the present study, the liver was the most commonly injured organ accounting for 34.78% (32/92) of injuries, whereas in a study by *Boone et al*,[9] liver was the second most commonly injured organ in the abdomen with damage occurring in 20-30% of blunt trauma overall. More than 50% of hepatihepatic injuries were grade II and grade III injuries. Around 18.75% (6/32) of liver injuries were associated with injuries to other organs, most commonly right kidney 50% (6/12). One patient with liver injury had injury to right adrenal gland. There were associated rib fractures in 50% patients (16/32) with liver injuries, more commonly on right side which was seen in 83.3% cases (10/12). The associated rib fractures have also been reported by *Boone et al* who

found rib fractures in 33% of cases with hepatic injuries.[9] Five out of six i.e. 31.25% patients with liver injury had concomitant injury to chest either in form of lung contusion, atelectasis or pleural effusion. More than 50% of hepatic injuries were grade II and grade III injuries. The spleen was the third most commonly injured organ accounting for around 10.8% (10/92) of injuries whereas in a study by *Mirvis et al*,[10] the spleen was the most frequently injured organ accounting for around 40% of all solid organ injuries. Around 40% (4/10) of splenic injuries were associated with injuries to other organs. There were no associated rib fractures. Associated chest injuries were present in 20% (2/10) of patients, either in form of lung contusion, atelectasis, or pleural effusion. Grade II injuries accounted for around 80 % of splenic injuries. In the present study 60% (6/10) patients with splenic injuries were managed non-operatively. The non-operative management was successful in 100% of patients with blunt splenic trauma i.e. none of the patients who were managed conservatively required delayed laparotomy.

In the present study, multiple organ injuries were seen in around 17.39% (16/92) of cases with liver and right kidney injured simultaneously in 37.5% (6/16) cases. Around 62.5% (10/16) patients with multiple organ injuries were managed conservatively unlike the study performed by *Pieper et al* who found that the patients in whom CT detects multi-organ "package" injuries (e.g. spleen and left kidney; left lobe of the liver; and pancreas) are more likely to undergo surgical intervention.[11]

In the present study, the kidney was second most common injured organ. Renal injuries were seen in 15.2% (14/92) of cases with right renal injury occurring in 57% (8/14) and left renal injury in remaining 43% (6/14). Around 57% (8/14) of renal injuries were associated with injuries to other organs, most commonly liver in cases of right renal injury and spleen in cases of left renal injury. In a study by *Smith et al*,[12] the kidneys were injured in 10% of patients with blunt abdominal trauma and were the most frequent urinary tract organ to suffer injury.

In the present study, grade III and grade IV renal injury was seen in 43% and 57% of cases respectively. There was no case with grade I and II injury. Among the 14 patients with renal injury 71.4% (10/14) were managed conservatively. Out of 8 patients with grade IV injuries 50% (4/8) were managed conservatively. All cases of grade III injury were managed conservatively. With the help of multi detector CT it was possible to accurately characterize the renal injuries and to rule out other associated injuries requiring urgent intervention as a result of which unnecessary laparotomy was avoided in a number of patients sustaining blunt renal trauma. Similar conclusions were drawn in a study by *Quinlan et al*[13] i.e. CT is recommended for detection and characterization of the grade of injury, for qualitative assessment of renal function, and to rule out associated intraabdominal injury that may warrant immediate surgery.

In the present study, pancreatic injuries were observed in around 6.52% (6/92) cases, in contrast to a study by *Wong et al*[14] who found pancreatic injury to be relatively uncommon, occurring in less than 2% of blunt abdominal trauma patients. Sixty six (66%) percent of pancreatic injuries were grade II injuries and 33.3% were grade I. The pancreatic injuries were associated with injuries to liver in 66.6% (4/6) of cases, injuries to kidneys in 66.6% (4/6) of cases involving right and left kidney separately and injuries to spleen in 33.3% (2/6) of cases. In a study by *Bradley et al*[15] it was observed that isolated pancreatic injuries are rare, and associated injuries, especially to the liver, stomach, duodenum, and spleen, occur in over 90% of cases. In the present study, out of 6 patients with pancreatic injuries 66.6% (4/6) were managed conservatively. Out of 4 patients with grade II injuries 50% (2/4) were managed conservatively. Two (2) cases of grade I injury were managed conservatively.

In the present study, bowel and mesenteric injuries were seen in around 13.04% (12/92) of cases. The most common sign of bowel injury in this study was bowel wall thickening, extraluminal air, extravasation of oral contrast, mesenteric thrombosis and evidence of bowel ischemia. Eight (8/12) patients had bowel injury, whereas only four (4/12) patients had mesenteric injury. The mesenteric hematomas were associated with hemoperitoneum without solid organ injuries in 100% (4/4) patients.

CONCLUSION

In this study CT scan was highly useful in diagnosis of blunt abdominal trauma. OIS (organ injury scale) grading, quantification of hemoperitoneum and anatomical site of organ injury predict the management protocols in the majority of our patients. Result of this study shows that CT scan is a superior diagnostic modality in the diagnosis and management of blunt abdominal trauma. The use of multi detector CT in initial triage of clinically stable patients with blunt abdominal trauma results in reduction in number of unnecessary laparotomies and helps guiding initial management in emergency department in virtually every patient with high success rate.

ABSTRACT

Background: Diffusion weighted imaging (DWI) has a wide range of applications in the evaluation of intracranial pathological conditions. It provides a specific diagnosis in few situations, and adds to the information provided by conventional sequence in many others.
Methods: The present study was conducted in the Department of Radiology, Dr. S. N. Medical College, Jodhpur, Rajasthan. Participants after understanding the study protocol and procedure, were asked to give their written consent for the study.
Results: In the study group of 115 patients (41%) were females and (59%) males. Infarcts comprised 45.2% of the total cases out of these acute infarcts constituted 30 cases (57.7%); 18 (34.6%) chronic infarcts and 4 (7.6%) were subacute infarcts. All cases of acute infarcts and 50% of subacute infarcts showed diffusion restriction. None of the chronic infarcts showed true restriction of diffusion. Among intra axial tumours true restriction was noted in 6 cases. 40% of glioblastoma multiforme showed true diffusion restriction. None of the low-grade gliomas or anaplastic astrocytomas showed diffusion restriction. 75% of medulloblastomas and 50% of lymphomas showed diffusion restriction. All cases of intracerebral abscesses showed true diffusion restriction. The cystic or necrotic component of none of the brain tumours included in this study showed diffusion restriction. All cases of arachnoid cysts seen in this study had low signal on DWI. 33% of meningiomas showed restricted diffusion in this study likely reflecting their high cellularity. All cases of HII showed true diffusion restriction. 25% of these cases showed no signal change on T2WI. Also, the extent of abnormality was noted to be more on DWI than on T2WI. Two cases of extradural empyema seen in this study showed restricted diffusion similar to abscesses. Hypertensive encephalopathy and demyelination did not show restricted diffusion reflecting absence of cytotoxic oedema in these conditions.
Conclusions: DW MRI helps in differentiating and characterizing intracranial lesions.

Keywords: ADC (Apparent diffusion coefficient), DWI, Intracranial lesions, MRI (Magnetic resonance imaging), T1W (T1 weighted), T2W (T2 weighted)

INTRODUCTION

Diffusion weighted imaging (DWI) is a technique that assesses local environment at the cellular level to determine changes in the random movement of water protons. Whereas DWI is most often used to identify acute arterial ischemia, other processes that interfere with or restrict the movement of water can cause notable changes on DWI, including neoplastic lesions, encephalitis, pyogenic abscesses and occasional

demyelinating diseases. Reduced diffusion can be seen in highly cellular tumors such as lymphoma, meningioma and glioblastoma. Several reports have suggested an inverse correlation between ADC value and glioma grade 2 to grade 4 astrocytoma.[1]

The signal intensity of gliomas on DWI is variable (hyper, iso or hypo intense), and a subtle hyper intensity is a common nonspecific finding. Tumor cellularity is probably a major determinant of ADC values of brain tumors, although probably not the only one. ADC values cannot be used in individual cases to differentiate glioma types reliably (the ADC values of patients with grade 2 astrocytoma and glioblastoma overlap). The ADC values of solid gliomas, metastasis and meningioma were in the same range. In cases of lymphomas, however there was a good contrast with the white matter, with strongly reduced ADC values. Further studies are needed to define clearly the ability of DWI to help differentiate various brain tumors and to help grade gliomas.[2]

DWI is useful in providing a greater degree of confidence in distinguishing brain abscesses from cystic or necrotic brain tumors than conventional MRI.[3] Thus, it may increase the diagnostic accuracy when combined with other sequences. Likewise, in Creutzfeldt-Jakob disease, DW imaging helps differentiate from infarct by showing persistent restricted diffusion.[4]

Thus, diffusion weighted imaging (DWI) has a wide range of applications in the evaluation of intracranial pathological conditions. It provides a specific diagnosis in few situations, and adds to the information provided by conventional sequence in many others.

METHODS

The study was conducted in the Department of Radio diagnosis, Dr. S. N. Medical College and associated group of hospitals, Jodhpur. Imaging was done with Philips 1.5 tesla magnetic resonance imaging equipment for one year from 2013 to 2014.

Inclusion criteria

All patients with diffusion weighted magnetic resonance imaging reference for infarction, hypoxic ischemic injury, infective condition, tumors, demyelination, metabolic and toxic insult to brain, Degenerative disorder irrespective of age and sex were included in the study.

Exclusion criteria

Patients who are detected to have intracranial bleed were excluded from the study.

Patients underwent the examination after contraindications for MRI were excluded and consent was taken. All the MRI scans in this study were performed using 1.5T MRI scanner. MRI Protocol consisted of the following:

- A head coil was used
- Axial diffusion weighted images of the brain
- Sagittal T1W images of the brain
- Axial T2W FLAIR images of the brain
- ADC images were reconstructed from the diffusion weighted images.

Table 1: MRI protocols.

	DWI	T2-FLAIR axial	T1-FLAIR sagittal
TE	5000	8002	2060
TE	80	86	20
TI		2000	650
Matrix	128*192	256*320	224*384
No. of excitations	2	1	1
Thickness	5 mm	5 mm	5 mm
Section spacing	1.5 mm	1.5 mm	1.5 mm
FOV	24*30	24*24	24*24
Imaging time	45 sec	1min 25 sec	1 min. 25 sec

Data evaluation

The observations of these patients were compiled and analyzed. All statistical analyses were conducted using the SPSS statistical package (version 16.0).

RESULTS

The present study was carried out to describe imaging characteristics of various intracranial lesions on DWI and to compare them with ADC and T2 FLAIR images.

Age wise distribution of patients

The age of the patients with intra cranial lesions ranged from 3 days to 78 years with a mean of 43.97±2.04. The patients involved in the study were divided into 7 age groups viz. 0-10 years, 11-20 years, 21-30 years, 31-40 years, 41-50 years, 51-60 years and 61-70 years. There were nine patients (7.8%) in 1-10-year age group, ten (8.6%) in 11-20-year age group, ten (8.6%) in 21-30-year age group, sixteen (13.9%) in 31-40-year age group, sixteen (13.9%) in 41-50 year age group, twenty three (20%) in 51-60 year age group, twenty five (21.7%) in 61-70 year age group, six (5.2%) in 71-80 year age group as given in Table 2.

In the present study 31 (41%) were females and 84 (59%) males. The mean age among females was 50 years and in males was 44 years. In the present study, majority were infarcts which constituted 52 cases (45.2%), 4 cases of hypoxic ischemic encephalopathy (3.4%) were also included. The other cases were tumors (31.3%) of which 19 (52.8%) were intra axial and 17 (47.2%) were extra

axial tumors, 15 infective conditions (13%), 4 cases of demyelination (3.4%) and 4 other miscellaneous conditions (3.4%). These included 1 case of adrenoleucodystrophy, 1 periventricular leukomalacia, and 2 posterior reversible encephalopathy syndrome (PRES) cases.

Table 2: Age wise distribution.

Intra cranial lesion	Age (years) range								Total
	0-10	11-20	21-30	31-40	41-50	51-60	61-70	71-80	
Abscess		1	1	1					3
ADEM	1								1
Acute infarct					4	11	14	1	30
Adrenoleucodystropy	1								1
Anaplastic astrocytomas				1	1				2
Arachnoid cyst		2	2	1					5
Chronic infarct					1	5	7	5	18
Demyelination toxic				1					1
Epidermoid cyst				1					1
Extradural empyema			1	1					2
GBM						2	3		5
Hemangioblastoma					1				1
HSV encephalitis			1						1
Low grade glioma		1		3					4
Lymphoma						1	1		2
Medulloblastoma		4							4
Meningioma			1	2	5	1			9
Multiple sclerosis				1	1				2
NCC granuloma			1	2					3
PVL	1								1
Pilocytic astrocytoma	1								1
PRES		1	1						2
Preterm HII	3								3
Profound term HII	1								1
Schwannoma				1		1			2
Subacute infarct					2	2			4
TB granuloma	1	1	2	1	1				6
TOTAL	9	10	10	16	16	23	25	6	115

In present cohort, 82 cases (71.2%) showed hyper intensity on DWI of which true restriction (hyper intense on DWI and hypo intense on ADC) was noted in 52 patients (45.2%). This constituted 63.4% of the cases showing diffusion restriction. T2 shine through was noted in 30 patients (26%). This constituted 36.6% of the cases showing diffusion restriction. 52 cases (45.2%) showed hypo intensity on ADC images. All of these were hyper intense on DW images. 13 patients (11.3%) showed T2 washout (hyper intense on T2WI and isointense on DWI). 5 patients (0.43%) showed no signal change on DWI or ADC images. 51 patients (44.3%) had lesions that showed increased diffusivity (hyper intense signal on ADC image). Of these 15 (13%) were hypo intense on DWI. This constituted 29.4% of the cases showing increased diffusivity. 13 of these showed T2 washout, and 23 showed T2 shine through.

Infarcts constituted 52 cases (45.2%) of the total cases in this study. Of this 30 (57.7%) were acute infarcts, 18 (34.6%) were chronic infarcts and 4 (7.6%) were subacute infarcts. The age group of patients with infarcts ranged from 43 to 78 years with a mean age of 60 years. There were 13 (25%) females and 39 (75%) males among these cases. In 30 cases (58%) the infarcts were in MCA territory, in 4 cases (8%) they were in ACA territory, in 11 cases (21%) the infarcts were in PCA territory and in 7 cases (13%) they were in basilar artery and vertebral artery territory. All 30 cases (100%) of acute infarcts showed true diffusion restriction with hyper intensity on DWI and hypo intensity on ADC images. Of these, 26 cases (86.66%) showed hyper intensity on T2W images. The remaining 4 cases (13%) showed no signal change on T2W images.

Of the 18 cases of chronic infarcts, ADC signal was increased in all, suggesting increased water diffusivity. In 8 cases (44.44%), there was hypo intensity on DWI and T2 FLAIR images with hyper intensity on ADC images indicating encephalomalacia. T2 shine through was noted in 10 cases (55.55%). None of the cases showed T2 washout. Out of 4 cases of subacute infarcts, 2 (50%) showed true restriction and 2 (50%) showed T2 shine through.

Four cases of hypoxic ischemic injury were included in this study, age range of 3 days to 15 days. Three cases were preterm neonates and one was a term neonate. All four cases showed true diffusion restriction. 3 of four cases (75%) showed hyper intensity on T2 FLAIR images, and 1 (25%) did not show any change on T2 FLAIR images. The extent of abnormality was noted to be more on DW and ADC images than on T2 FLAIR images.

In study major, infective conditions (15 in total) were tubercular granulomas 6 (40%), Neurocysticercosis (NCC) granulomas 3 (20%), abscesses 3 (20%), extradural empyemas 2 (13.3%) and HSV encephalitis 1 (6.7%). True restriction of diffusion was noted in 7 (46.66%) cases. This included 2 tubercular granulomas 3 abscesses and 2 extradural empyemas. Thus 33.33% of tubercular granulomas, 100% of abscesses and 100% of extradural empyemas showed true diffusion restriction. T2 washout was seen in all 3 cases (100%) of NCC granulomas and 3 cases (50%) of tubercular granulomas. T2 shine through was seen in 1 case of tubercular granuloma and one case of HSV encephalitis.

There were 19 cases of intra axial tumors with age ranging from 10 to 68 years with 5 females and 14 males. This included 2 cases of anaplastic astrocytoma, 5 cases of glioblastoma multiforme, 1 hemangioblastoma, 4 low grade gliomas, 4 medulloblastomas, 1 pilocytic astrocytoma, and two cases of lymphomas. 6 cases (31.6%) showed true diffusion restriction. Of these 2 were GBM, 3 were medulloblastomas, and one was lymphoma. Thus 40% of GBM, 75% of medulloblastomas, and 50% of lymphomas showed true restriction of diffusion.

T2 shine through was noted in 8 cases (42.1%). This included all 2 cases of anaplastic astrocytomas, 3 cases (60%) of GBM, 2 cases (50%) of low grade gliomas and 1 (50%) case of lymphoma. T2 washout was seen in one case of hemangioblastoma and 2 cases (50%) of low grade gliomas.

17 cases of extra axial tumors with an age range of 14 to 52 years, mean 36 years were included in this study. Of these 6 were females and 11 were males. These were 5 cases of arachnoid cysts, 1 epidermoid cyst, 9 cases of meningiomas and 2 cases of schwannomas. True restricted diffusion was noted in 4 cases (23.52%). This included the single case of epidermoid cyst and 3 cases (33.3%) of meningiomas. In one case of meningioma, T2 shine through was noted. In 6 (66.6%) cases of meningiomas, T2 FLAIR showed iso to hypo intense signal probably due to high cellularity and presence of calcification. 1 case (50%) of schwannoma showed T2 washout.

Out of four cases of demyelination, two (50%) were multiple sclerosis, one was a case of toxic demyelination and one was a case of ADEM. All the lesions showed hyper intensity on T2 FLAIR images. True restriction of diffusion was not noted in any of the cases. T2 washout was seen in one case of multiple sclerosis (50%) and in toxic demyelination. No change was noted on DWI or ADC images in one case (50%) of multiple sclerosis and in ADEM.

Miscellaneous other lesions like 1 case of adrenoleucodystrophy, 1 case of periventricular leukomalacia and 2 cases of posterior reversible encephalopathy syndrome were detected. All the lesions showed hyper intensity on T2 FLAIR images. True restriction of diffusion was not noted in any of the cases. T2 washout was seen in one case of PRES. No change was noted on DWI or ADC images in one case of PRES. T2 shine through was noted in adrenoleucodystrophy.

DISCUSSION

Diffusion weighted MRI provides image contrast that is different from that provided by conventional MRI sequences. It provides a technique for mapping proton contrast that reflects the microvascular environment. This imaging technique is sensitive to early ischemic insult. DWI is performed with a pulse sequence capable of measuring water translation over short distances. This water diffusion is much slower in certain pathological conditions as compared with normal brain.[5] In this study, 115 patients with intracranial lesions detected on DW MRI of the brain were included.

The sensitivity and specificity of DWI in the detection of acute ischemia is 100%. The difference in sensitivity of DWI and conventional MRI sequences is more in the initial time period and decreases as time progresses. Results of our study are similar with a study done by Gonzalez et al who concluded that DWI is superior to conventional MRI in the diagnosis and characterization of acute infarct.[6] In 13% of acute infarcts, no change was noted on T2WI. Thus, DWI was noted to be superior to T2WI in detection of acute infarcts. In subacute infarcts and chronic infarcts, abnormal signal was noted on T2WI and on DWI in all patients.

Thus, there was no difference in their sensitivity for later stages of infarcts. Rima K et al showed that restricted diffusion is present in all patients on DWMR studies obtained within 24 hours of the onset of symptoms, and in 94% of patients scanned after 2 weeks after ictus.[5] In this study, subacute infarcts were defined as patients in

whom imaging was performed between 2 and 14 days after symptom onset. Schwartz R et al, true diffusion restriction was noted in 50% of patients with subacute infarcts. The other 50% showed T2 shine through. In this study, 58% of infarcts were noted to be in MCA territory, 21% in PCA territory, 8% in ACA territory and 13% in vertebral artery and basilar artery territory. This is comparable to a study done by Zwan VD et al, which showed that MCA territory is the most common site for infarcts and ACA territory is the least common among major arterial territories.[8]

In chronic infarcts, the signal on DWI and ADC images is variable and depends on a combination of T2 signal and increased ADC values. The T2 signal is also affected by the onset of cystic encephalomalacia Schaefer PW et al.[9] In the present study T2 shine through was noted in 55.5% of chronic infarcts and cystic encephalomalacia was noted in 44.4%.

Hypoxic ischemic injury

Fu JH et al, compared conventional MRI sequences to DWI in the evaluation of HII and found that DWI showed abnormal high signal intensity in the brain in patients in whom the conventional MR sequences were initially normal.[10] Schaefer et al, concluded that HII lesions not seen on routine MR images are identified on DW MR Images.[9] When lesions are identified on conventional images, lesion conspicuity is increased and lesion extent is seen to be larger on DW MR Images. All cases of neonatal HII included in this study showed true diffusion restriction. In 25% of cases there was no abnormality on T2 FLAIR images. The extent of abnormal signal was much more in the remaining 75% of cases on DWI, than that showed by T2W images.

Infections

Chang et al, have showed that abscess cavity shows high signal intensity on DWI and a low signal on ADC image. This is not seen in the necrotic component of brain tumors. They concluded that DWI may enable one to distinguish brain tumors from necrotic tumors. Also, it helps in the evaluation of partially treated abscesses and to look for their recurrence. In the present study 100% of cases of abscess showed true diffusion restriction. The cystic or necrotic component of none of the tumors included in this study showed restricted diffusion. In 33.3% of the tubercular granulomas observed in this study, diffusion restriction was noted, probably denoting presence of necrosis. 50% of tubercular granulomas and 100% of NCC granulomas could not be detected on DWI alone and needed ADC and T2W images for lesion detection probably due to the poor spatial resolution of diffusion weighted imaging. All two cases (100%) of extradural empyemas noted in this study showed true diffusion restriction. The thick nature of this collection causes reduced water diffusivity similar to abscesses.

Tumors

Intra axial tumors

In the present study, 40% of GBM, 75% of medulloblastomas and 50% of lymphomas showed true diffusion restriction. None of the low-grade gliomas or anaplastic astrocytomas showed restricted diffusion. The single case of hemangioblastoma seen in this study showed high signal on ADC images in its solid component suggesting high water diffusivity. DWI can differentiate between tumor and infection and can provide information about the cellularity of tumors thereby helping in characterization and grading of tumors. Cruz CH et al, showed that highly cellular tumors such as high-grade gliomas and lymphomas can have low ADC values and show restricted diffusion.[11] It was also shown that medulloblastomas may be differentiated from other pediatric brain tumors by presence of diffusion restriction. The solid portion of hemangioblastomas has high ADC values due to their rich vascular spaces. The findings of this study were similar.

Extra axial tumors

Schaefer et al, showed that conventional MR cannot be reliably used to differentiate these two lesions as both have CSF like signal intensity on conventional MR sequences.[9] This was also demonstrated in a study by Cruz et al, in which epidermoid cysts had ADC values similar to brain parenchyma while arachnoid cysts had ADC values similar to CSF.[11] In the present study all 5 cases of arachnoid cysts had signal similar to CSF on DWI and ADC images. The single case of epidermoid cyst noted in this study had restricted diffusion. Tadeusz et al and Cruz et al concluded that most meningiomas are isointense on DWI.[11,12] Only few may show restricted diffusion depending on their cellularity. In their study 23% of meningiomas showed restricted diffusion. This study had similar results with 33% of meningiomas showing true diffusion restriction. Schwannomas show high signal on ADC images with no restricted diffusion reflecting lack of high cellularity.

Demyelination

Four cases of demyelination seen in this study did not show restricted diffusion and had increased signal on T2 FLAIR images. Studies done by Christiansen P et al and Larsson H et al, have shown that most foci of demyelination do not show restricted diffusion.[13-14]

Others

Schwartz et al, showed that the edema of hypertensive encephalopathy is of vasogenic type.[7] The results of this study are similar. None of the cases of PRES seen in this study had features of restricted diffusion. No signal change was noted in periventricular leukomalacia seen in

this study, while the single case of adrenoleucodystrophy showed features of vasogenic edema.

CONCLUSION

Diffusion weighted MRI is a valuable technique that provides unique information about the physiological state of brain tissue. By using a combination of various MR sequences coupled with DWI and ADC images a valuable diagnosis may be provided to the clinicians. In this study the signal characteristics of various lesions on DWI, ADC, T2FLAIR and T1W images were studied. Diffusion weighted MRI has been proven to be of excellent use in the characterization of infarcts and in the detection of acute infarcts. It is especially useful in the initial few hours of the ischemic insult when conventional MR sequences may be inconclusive and may not detect the infarct. Thus, DW MRI helps in differentiating and characterizing various intracranial lesions.

ACKNOWLEDGMENTS

Authors would like to thank all his colleagues in department of Radiology for their supports. Furthermore, author wishes to give his special thanks to all those patients enrolled in study and their relatives for their outstanding support and cooperation to conduct this study.

Abstract

Background: It has been postulated that two clinical subtypes of psoriasis, namely the "early onset" and the "late onset" can be characterized based upon the age of onset. However precise data to differentiate the two clinical subtypes of psoriasis are not available. **Objective:** To investigate the clinical characteristics of early and late onset psoriasis in the Mauritian patient. **Methodology**: A cross-sectional study of consecutive 55 patients of psoriasis was carried out at the Skin Outpatient department of a regional hospital in Mauritius. The Case study method was used to collect the clinical data and was recorded in a comprehensive Case Record Form. The data was statistically analyzed using SPSS 22 (Statistical Package for the Social Sciences) software. **Results:** A bimodal distribution of onset of psoriasis was observed with peak between 20-30 years age in 12 (21.8%) of patients, and between 49-59 years age in 24 (43.6%); 27 (49.1%) patients had onset < 40 years ; 28(50.9%) patients had onset ≥ 40 years. In Early onset psoriasis co-morbidities were present in 22/27 (66.7%) of which was significant. In Late onset psoriasis 22/28 (78.6%) were male and nail involvement was seen in 26 (78.8%) male patients as compared to 7(21.2%) female patients, which was statistically significantly. Total Body Surface Area larger than 10% was observed in 12 (44.4%) in early onset as compared to 6 (21.4%)in late onset psoriasis but this was statistically not significant. **Conclusions:** The psoriasis had a bimodal distribution of onset. The psoriasis of Late onset showed a male preponderance, frequent nail involvement and psoriatic arthritis of axial joints. The clinical features validated existence of two clinical subtypes of the disease separated by the age of onset.
Key words: Clinical subtypes, age of onset, Total Body Surface Area (TBSA), psoriatic arthritis.

INTRODUCTION

Worldwide prevalence rates of psoriasis range from 0.6 to 4.8%.[1, 2]The disease tends to have a bimodal distribution of onsetwith major peak occurring at age of 20-30 years, and later a smaller peak occurring at age of 50-60 years.[3, 4]Two sub-populations of patients of psoriasis, early onset and late onset type, with distinct clinical and immuno-genetic characteristics have been identified. The two types show different evolutionary features.[5] Patients with early age onset of psoriasis are more likely to have a family history of psoriasis and more unstable with frequent remissions and relapses. The disease tends to be more severe as measured by involvement of Total Body Surface Area (TBSA) and is more resistant to treatment.[3, 4]. There is a higher incidence of obesity, diabetes, dyslipidaemia, hypertension and major cardiovascular events (MACE). HLA Cw6, B13 and B17 are the specific markers of the early onset type of psoriasis.[6, 7]

Late onset typepsoriasis involves less TBSA, is a milder disease and is more likely to be associated with psoriatic arthritis, nail involvement and palmoplantarpustular involvement.[3, 4]Family history is less frequent and HLAB27, Cw2, B44 and Cw5 seem to be associated with the late onset type of psoriasis.[6, 7] The purpose of our study was to study the clinical features of early age and late onset psoriasis in the Mauritian patient.

How to site this article: Yogesh M Shah, Alka D Gore, Bibi Kaushur D Khodaboccus. Early and late onsetpsoriasis: A clinical study. *MedPulse – International Medical Journal* October 2015; 2(10): 668-671. http://www.medpulse.in (accessed 16 October 2015).

MATERIALS AND METHODS

The study was carried out at the Skin outpatient department of a regional hospital in Mauritius from February 2011 to October 2012. A cross-sectional study of consecutive 55 patients of psoriasis of either sex was carried out. The permission of the Regional Health Director of the Hospital and an informed consent of the patient were obtained for the study. A clinicaldiagnosis of 'psoriasis vulgaris' was made, when typical well circumscribed, erythematous, scaly, chronic plaques were observed on the scalp and the extensors, 'guttate psoriasis' if there was an abrupt eruption of typical psoriatic lesions of papular type, 'pustular psoriasis' if tiny sterile pustules were found on the surface of a psoriatic plaque and 'psoriatic erythroderma' if extensive erythema and superficial scaling of more than 90% of the body surface occurred in a known case of psoriasis.[8, 9] Patient in remission of skin lesions of psoriasis or guttate psoriasis found to be serologically positive for VDRL or TPHA test were excluded from the study. The Case study method was used to collect the clinical data like age of onset, clinical type of psoriasis, the Body sites and the TBSA affected, involvement of the nail and the joints and presence of co-morbidities like obesity, hypertension, diabetes mellitus and cardiovascular diseases. Severity of the disease was assessed, by using percentage of the TBSA affected due to psoriasis. As per Finlay's concept of 'Rule of Tens', area covering more than 10 hand prints, indicating BSA more than 10%, was considered as severe psoriasis.[10] All the data was recorded in a comprehensive Case Record Form (CRF). The data collected was statistically analyzed using SPSS 22 software (Statistical Package for the Social Sciences). The continuous data was described as mean and standard deviation. The categorical data was expressed as frequencies and percentages. Analysis of categorical data was done by chi-square test or Fisher's Exact test. A p value of <0.05 was considered as statistically significant.

RESULT

Out of 55 patients registered in the study, men accounted for 36 (65.5%) and women 19 (34.5%). Male to female ratio was approximately 2:1.The age of patient varied from 20 to 76 years with mean age being 48.85 years, ± SD 13.49. Majority of patients, 51 (92.7%) were of age 30 years and above; 19 (34.5%) of patients were in their sixth decade. Least number of patient, 2 (3.6%) and 4 (7.3%), were recorded in the two extreme age groups (70-79 and 20-29 years, respectively). The number of patients with family history of psoriasis were 23(41.8%) out of which19 (34.7%) patients reported a first degree relative with psoriasis, 2 patients had a second degree relative and in 2 cases third degree relatives were suffering from psoriasis.

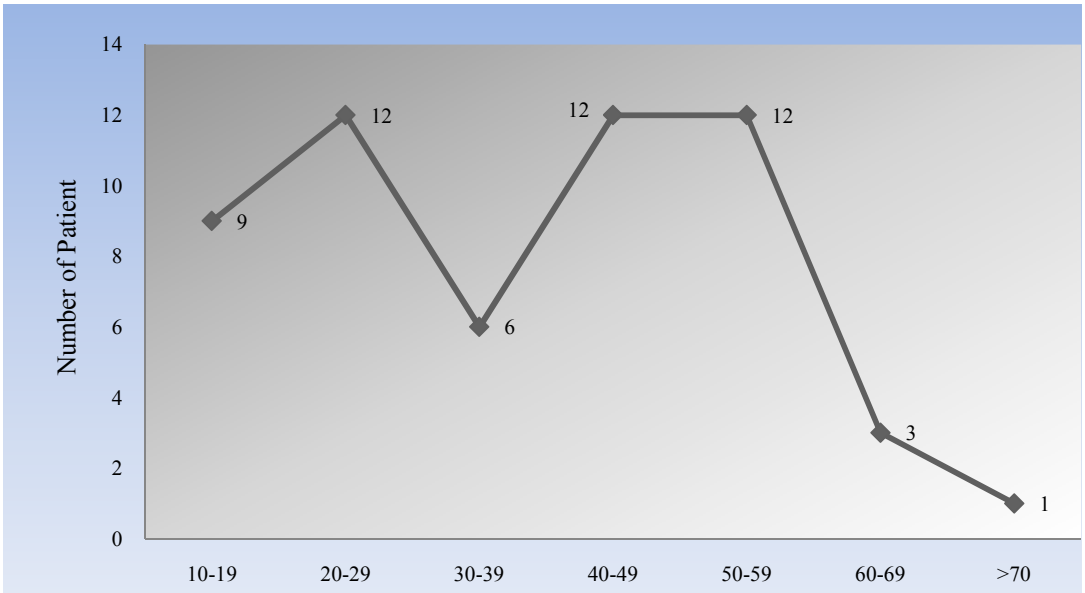

Figure 1: Bimodaldistribution

The age at onset of psoriasis of the skin was12 to70 years; mean being 37.7 years ± SD 16.0. Two peaks were observed, first during the third decade in 12(21.8%) patients, second during the fifth and sixth decades in 24(43.6%) subjects;27(49.1%) patients had onset of psoriasis below 40 years (early onset);28(50.9%) patients reported onset of psoriasis ≥ 40 years (late onset).

Table 1: Gender distribution, family history and TBSA**in 2 subtypes ofpsoriasis.

Variables		Psoriasis		p value
		Early onset (n=27)	Late onset (n=28)	
Gender	Male	14 (51.9%)	22 (78.6%)	p = 0.037*
	Female	13 (48.1%)	6 (21.4%)	
Family History	Yes	11 (40.7%)	12 (42.9%)	p = 0.874
	No	16 (59.3%)	16 (57.1%)	
Co-morbidities	Yes	22 (66.7%)	11 (33.3%)	p = 0.002*
	No	5 (22.7%)	17 (77.3%)	
TBSA	<10%	15 (55.6%)	22 (78.6%)	p = 0.069
	>10%	12 (44.4%)	6 (21.4%)	

*Statistically significant **Total Body Surface Area

Gender distribution in Early onset psoriasisis almost equal, butin Late onset psoriasis a male preponderance, almost 4: 1, was observed. Co-morbidities were present in 22/27 (66.7%) of Early onset psoriasis. Total Body Surface Area (TBSA) involvement larger than 10% was observed inalmost twice the number of patients in Early onsetas compared toLate onset psoriasis.Chi-square test was performed, and there is statistically significant association between gender and co-morbidities withsubtype of psoriasis; but no significant association was found between family history and disease severity (BSA). Late onset psoriasis was found more in male patients. Nail psoriasis was more common in Late onset psoriasis, 19 (67.9%) patients as compared to 14 (51.9%) patients in Early age onsetpsoriasis. In contrast, Joint involvementwas more frequent in patients of Early age onset, 9 (29.6%) as compared to Late onset psoriasis5 (14.3%) patients.Differences between the two groups having nail or joint involvement were statistically not significant.

Table 2: Nail involvement as per gender and type of psoriasis.

Variables		Nail involvement	p value
Gender	Male	26 (78.8%)	p = 0.000*
	Female	7 (21.2%)	
Psoriasis	Early onset	14 (42.4%)	p = 0.298
	Late onset	19 (57.6%)	

*Statistical significance

Nail involvement was more among male patients, 26 (78.8%) patients compared to female patients, 7(21.2%). Male to female ratio was approximately, 4:1. Proportion of male patients with nail involvement was significantly more ($p < 0.05$). No statistical significance was found in the Early and Late onset psoriasis patients.

Table 3: Joint involvement as per gender, subtype of psoriasis and family history.

Variables		Joint involvement	p value
Gender	Male	4(28.6%)	p = 0.085
	Female	10(71.4%)	
Psoriasis	Early onset	9(64.3%)	p = 0.254
	Late onset	5(35.7%)	
Family History	Positive	5(35.7%)	p = 0.254
	No	9(64.3%)	

Joint involvement was predominantly within the female population 10(71.4%), compared to males 4(28.6%). Male to female ratio was 2:5.On performing the z-test (Standard error of difference between two proportions) this finding was statistically not significant ($p > 0.05$).Majority of patients, 9(64.3%) with joint involvement had early age onset disease; From among patients with joint involvement 5/14(35.7%) had a positive family history of skin psoriasis; but this is not statistically significant.

Table 4: Type of joints involvedas pertype of psoriasis and family history

Variable		Types of joint involved in psoriasis		P value
		Non Axial joints	Axial joints	
Psoriasis	Early onset	6(75.0%)	3(50.0%)	P = 0.580
	Late onset	2(25.0%)	3(50.0%)	
Family History	Yes	4(50.0%)	1(16.7%)	P = 0.3
	No	4(50.0%)	5(83.3%)	

Non axial joints were mostly involved in Early onset psoriasis. Majority of patients 5(83.3%) with axial joints involvement did not have a positive family history. Associations of axial and non-axial joints to the Early or Late onset and family history were not statistically significant.

DISCUSSION

Plaque psoriasis was the predominant clinical type in this study. Relation of Early onset and Late onset psoriasis to gender,involvement of Total Body Surface Area (TBSA), nail and the joints were studied. A bimodal age of onset was observed with first peak during 20-30 years and second peak between 49-59 years of age was observed confirming the observations of Ferrándiz C *et al*[3] and Henseler T *et al*.[4] Early onset psoriasis revealed co-morbidities in 22/27 (66.7%) which was significant. A larger percentage of patients with family history and TBSA involvement was seen in almost twice the number of patients as compared to the Late onset psoriasis but the figures were statistically not significant to confirm similar findings of Ferrándiz C *et al*[3]and Youn JI *et al*.[11] In Late

onset psoriasis a significant male preponderance, almost 4: 1, was observed. There was also a significant association ofLate onset psoriasis and nail involvement. Joint involvement was predominantly in the female with more frequent involvement of axial joints. The study revealed a bimodal age of distribution of onset of psoriasis, higher co-morbidities in the Early onset psoriasis and male preponderance with a higher incidence of nail involvement in the Late onset psoriasis.

CONCLUSION

The Early onset psoriasis revealed significantly higher co-morbidities. The late onset psoriasisshowed a male preponderance, frequent nail involvement and psoriatic arthritis involving axial joints.The clinical features of psoriasis studied confirmed the existence of two clinical subtypes of psoriasis however a more extensive study is required.

ACKNOWLEDGEMENT

We are thankful to the Director, the Dean, the Head of Department, Dept. of Dermatology, Dr D Y Patil Medical College, Mauritius, the Regional Health Director of J. N. Hospital, Rosebelle, Mauritius and the Ministry of Health and Quality of Life, Government of Mauritius for facilitating the above study.

Abstract

Background: The impact of psoriasis on QOL of the individual may vary considerably depending on various factors such as gender, age of onset and the type of disease. However no study of the same had been carried out in Mauritius. **Objective:** Aim was to study the impact of clinical and epidemiological features of psoriasis on the Quality of Life of the psoriatic patient. **Methodology:** The study was carried out in the Outpatient department of a regional general government hospital in Mauritius. It was a cross sectional study of consecutive 55 patients of psoriasis using the case study method. The clinical features of psoriasis were correlated to the impact of psoriasis on the Quality of Life of the patient. The data was analyzed using SPSS 22 software. **Results:** Out of a total of 55 patients of psoriasis 36 (65.5%) patients were men and 19 (34.5%) women; Association between gender and the PDI score was a statistically significant (p value=0.024). Larger percentage of female patients was seen with greater PDI score. PDI was significantly dependent on stress (p value = 0.003). The patients with stress had a PDI score > 20. Involvement of the Body surface area less than 10% was observed in 37 (67.3%) and >10% BSA in 18 (32.7 %); 16 (83.3%) patients with involvement of Body surface area >10% had PDI score >20. Psoriatic arthritis was observed in 14/55 (24.5%) patients and 13/14 (92.8%) patients of psoriatic arthritis had PDI score > 20. **Conclusion:** There was a significant association between the gender, stress, severity of the disease, psoriatic arthritis and the total PDI score. The disability due to psoriasis was more in females, when a larger Body surface area was affected and in cases of joint involvement.

Key words: Quality of Life, Psoriasis Disability Index (PDI) score, Psoriatic arthritis, Body surface area.

INTRODUCTION

Psoriasis is a recurrent and chronic systemic inflammatory disease with a wide spectrum of clinical patterns of skin, nail and joint involvement.[1,2] It is the most prevalent autoimmune disease in the United States, affecting approximately 7.5 million, or 2.2%, of the US population.[3] The most common type of psoriasis is Psoriasis vulgaris or plaque psoriasis. Symptoms of plaque psoriasis include erythematous plaques with silvery, micaceous scales. In most cases, the symptoms are mild and cover less than 3% of the body. However, for a small subset of individuals (8% of psoriasis patients), psoriasis can cover over 10% of the skin and is classified as severe.[4] Severe psoriasis can have a major impact on quality of life (QOL) of the patient. The impact of psoriasis on QOL of the individual may vary considerably depending on gender, the age, clinical type, the severity of the disease and involvement of the joints. Psoriasis is reported to have a greater impact on the quality of life of patients in the age 18 years to 45 years, with men subjected to a greater work-related stress as compared to women.[5] QOL was observed to be significantly more impaired in the older age group, particularly women, in another study.[6]

Symptoms, particularly itching, and severity of the disease as indicated by the total Body surface area (BSA) are reported to have negative impact on the QOL.[7] Psoriatic arthritis has a marked negative impact on the

How to site this article: Yogesh M Shah, Bibi Kaushur D Khodaboccus, Alka D Gore. Determinants of quality of life in psoriasis. *International Journal of Recent Trends in Science and Technology* November 2015; 17(1): 105-108 http://www.statperson.com (accessed 16 November 2015).

QOL and is an indication for treatment with immunosuppressant and or the Biologicals.[8] Various co-morbidities such as obesity, hypertension and cardiovascular disease may also influence the QOL of the psoriatic.

The chronic nature and course of the disease contribute to a lifelong burden.[9] Aim was to study various factors of the disease determining Quality of Life in psoriasis.

MATERIALS AND METHODS

It was an exploratory cross sectional study of consecutive 55 patients of psoriasis in the Skin Outpatient department of a regional government hospital in Mauritius. The study was carried out using the case study method. A permission of the Regional Health Director of the Hospital and an informed written consent of patient were obtained for the study. Only classical cases of psoriasis were included in the study. A clinical diagnosis of 'psoriasis vulgaris' was made when typical, well circumscribed, erythematous, scaly, chronic plaques were observed on the scalp and the extensors, and that of 'guttate psoriasis' was made when abrupt eruption of typical psoriatic lesions of papular type were observed. The diagnosis of 'pustular psoriasis' was made if tiny sterile pustules were found on the surface of a psoriatic plaque and with extensive erythema and superficial scaling of more than 90% of the body surface in a known case of psoriasis the diagnosis of 'psoriatic erythroderma' was made.[1,2] Patient of psoriasis who were in remission of skin lesions of psoriasis or those found to be serologically positive for VDRL or TPHA test were excluded from the study. The clinical data such as gender, age, duration of the disease, clinical type of psoriasis, the body sites and the Body surface area (BSA) affected, involvement of joints and presence of co-morbidities like obesity, hypertension, diabetes mellitus and cardiovascular diseases were recorded in a comprehensive Case Record Form (CRF). Severity of psoriasis was assessed by percentage of the total BSA affected due to the disease. As per Finlay's concept of 'Rule of Tens', area covering more than 10 hand prints, indicating BSA more than 10%, was considered as severe psoriasis.[10] A quantitative assessment of impact of psoriasis on QOL was done by the Psoriasis Disability Index (PDI) Questionnaire of A Y Finlay designed 30 years ago.[11] Since its introduction the PDI has been used widely as a tool for assessment of quality of life in psoriasis. It has been translated into at least 16 languages and has been used in published research in 20 countries.[12] A written permission for the use of PDI Questionnaire was obtained from Prof. A Y Finlay.

The PDI Questionnaire contained a total of fifteen questions, covering difficulties encountered under five different sections such as 'daily activities', 'at work', 'personal relationships', 'leisure activities' and 'treatment'. The patient assessed the impact of psoriasis on his QOL by selecting one answer from the choice of four answers; the answer 'very much' (scored 3), 'a lot' (scored 2), 'a little' (scored 1), 'not at all' or no answer (scored 0). The maximum score for the whole questionnaire could be 45 and minimum 0. The total PDI scores were put in two categories: patients with total PDI score of less than (<) 20 and patients with total PDI score of greater than or equal to (≥) 20.

The data collected was statistically analyzed using SPSS 22 software (Statistical Package for the Social Sciences). The continuous data was described as mean and standard deviation. The categorical data was expressed as frequencies and percentages. Analysis of contingency tables was done by Fisher's Exact test. The categorical data was analyzed by Chi-squared test. A p value of < 0.05 was considered as statistically significant.

RESULT

A total of 55 patients of psoriasis were studied. Age of patients ranged from 20 to 76 years with a mean age 48.85 years, ± SD 13.49; 36 (65.5%) patients were men and 19 (34.5%) women; 25 (45.5%) were employed and 18 (32.7%) unemployed.

Pruritus was noted in 32 (58.2%) patients. No statistically significant association between pruritus, episodes of exacerbation, disease severity (as indicated by BSA) and total Psoriasis Disability Index scores could be established.

Episodes of exacerbation of lesions within a year were observed in all 55 patients; 23 (41.8%) patients reported 1 to 2 exacerbation, 12 (21.8%) patients had more than 2 episodes of exacerbations of the disease.

Co-morbidities were present in 12 (40%) patients. They were Overweight (38.2%), Diabetes Mellitus Type II (32.7%), Hypertension (25.4%), Obesity (16.4%) and Cardiovascular disorders (12.7%).

Table 1: PDI (Psoriasis Disability Index) score as per gender, age of onset and stress

Variable	Number of Patients	PDI score groups		p value
		< = 20	> 20	
Gender				
Male	36	21 (58.30%)	15 (41.70%)	0.024
Female	19	5 (26.30%)	14 (73.70%)	
Age of onset				
< 40 years	27	9 (36.0%)	18 (60.0%)	NS
> 40 years	28	16 (64.0%)	12 (40.0%)	
Stress				
"No"	15	12 (80.00%)	3 (20.00%)	0.003
"Yes"	40	14 (35.00%)	26 (65.00%)	

NS: Not Significant Statistically

The gender and the PDI score were associated significantly (p value=0.024). A larger percentage of female patients were seen with greater PDI score. PDI was significantly dependent on stress (p value = 0.003). The patients with stress had a larger (>20) PDI score. Morphologically 53 (96.4%) patients were of Psoriasis vulgaris and1(1.8%) patient had Guttate psoriasis.

Table 2: PDI score as per Body site involved

Body site involved	Total Psoriasis Disability Index scores			p value
	≤20	>20	Total	
Limbs	25 (47.2%)	28 (52.8%)	53	NS
Trunk	16 (37.2%)	27 (62.8%)	43	0.02
Scalp	10 (40.0%)	15 (60.0%)	25	NS
Face	2 (28.6%)	5 (71.4%)	7	NS
Flexures	4 (26.7%)	11 (73.3%)	15	NS
Palms and soles	2 (50.0%)	2 (50.0%)	4	NS

NS: Not Significant statistically

A larger number of patients with psoriasis on the trunk had total PDI scores >20 which was statistically significant. Areas like the flexures, face and the scalp had more patients with high total PDI scores (>20) but were statistically not significant.

Table 3: PDI score as per Body surface area (BSA) and psoriatic arthritis

	Total number of patients	PDI groups		p value
		< = 20	> 20	
BSA				
< 10%	37	24 (64.90%)	13 (35.10%)	0.001
> 10%	18	2 (16.70%)	16 (83.30%)	
Psoriatic arthritis	14	1 (4.0%)	13 (92.8%)	0.001

16 (53.3%) patients with total body surface area (BSA) > 10% had a total PDI score o > 20 while 2 (8.0%) patients had total PDI score < 20, ($p<0.05$). A significant correlation was established between disease severity (BSA) and the total PDI scores. A significant proportion of variance of the PDI, was found to be dependent on BSA (23.1%) on performing a regression analysis.

Most of the patients 13 (43.3%) with joint involvement had higher total PDI score except for one patients who had a total PDI score of less than 20. On performing the Fisher's Exact test, a statistical significant association was found between the total PDI scores and Joint involvement ($p < 0.05$).

DISCUSSION

The study examined the relation of age, gender, pruritus, body site affected, clinical type and the severity of psoriasis to the total Psoriasis disability index (PDI) score. The PDI score is a quantitative measure of the impact on QOL.

Gupta MA *et al* has reported that Psoriasis has a greater impact upon the quality of life of patients in the range of age 18 years to 45 years, with men facing a greater work-related stress.[5] Samogna F *et al* reported that elderly people specially women were more adversely affected.[6] In this study also the female gender was associated with a larger PDI score. A larger percentage of female patients were seen with greater PDI score but age did not seem to have a significant negative impact on the QOL.

Patient-reported symptoms particularly itching, pain and scaling are reported to negatively affect work productivity.[7] No significant association between pruritus and total Psoriasis Disability Index scores could be established in this study. Stress had a negative impact on QOL.

Patients in the study were predominantly those of Psoriasis vulgaris. Most of the patients had lesions on limbs and the trunk. A larger number of patients with psoriasis on the trunk had high total PDI score. Areas like the flexures, the face and the scalp had more patients with a high total PDI score but were statistically not significant.

BSA involvement larger than 10% was considered to be a severe disease. This study noted an association between BSA and the total PDI score. BSA greater than 10% was observed in 18 (32.7%) patients; 16/18 patients had a PDI total score greater than 20. Horn *et al* also found a negative impact on QOL in moderate-to-severe psoriasis.[13] In contrast, a study from Kwa Zulu Natal, South Africa, reported a weak correlation of Psoriasis area severity index (PASI) with PDI.[14] The authors found that body sites like face, groin or genitalia when involved resulted in higher PDI score and these areas consisted of a smaller percentage of BSA.[14]

Almost all patients with joint involvement had higher total PDI score. Literature reports that patients with PsA have more bodily pain, decreased mental health, social functioning and a poorer quality of life compared to those with psoriasis alone.[15,16]

CONCLUSION

There was a significant association between the gender, stress, severity of the disease, psoriatic arthritis and the total PDI score. The disability due to psoriasis was more in females, at the time of stress and exacerbations, when a larger Body surface area was affected and in cases of associated Psoriatic arhritis. Areas like the flexures, the face and the scalp had more patients with a high total PDI score but were statistically not significant.

Abstract

Background: Psoriasis may be associated with Psoriatic arthritis in 6% to 42% of cases. Psoriatic arthritis can cause serious disability. No data about incidence of Psoriatic arthritis in patients of Psoriasis was available in Mauritius. **Objective:** To determine the prevalence of Psoriatic arthritis and its clinical types in Mauritian patients of psoriasis. **Methodology**: A cross-sectional study of consecutive 55 patients of Psoriasis was carried out by the case study method at a tertiary medical centre in Mauritius. The diagnostic criteria of Moll and Wright were used for the diagnosis and the classification of Psoriatic arthritis. The data collected was statistically analysed using SPSS16 (Statistical Package for the Social Sciences) software. A p value of < 0.05 was considered as statistically significant. **Results:** Psoriatic arthritis was observed in 14 (25.4%) of patients of Psoriasis. Female to Male ratio was 5:2. Clinical types of Psoriatic arthritis observed were Polyarthritis in 5 (35 %), a Combination of Spondylitis and Symmetric polyarthritis in 3 (29%), Oligoarthritis in 3 (29%) and Classical Isolated Distal interphalangeal joint involvement in 1 (7%) patient. The Proximal interphalangeal joints of the fingers were involved in 10 (71%), followed by the knee joint in 7 (50%) and the ankle joint in 7 (50%) of patients. **Conclusion:** Psoriatic arthritis affected female more frequently than male and the Polyarthritis type of psoriatic arthritis was predominant. The proximal-inter-phalangeal joints were most frequently involved.
Key words: Psoriatic arthritis, polyarthritis, spondylitis, oligoarthritis.

INTRODUCTION

Psoriasis is a recurrent and chronic systemic inflammatory condition predominantly involving the skin, the nails and the joints.[1,2] Worldwide prevalence rates of psoriasis range from 0.6 to 4.8%[3,4] out of which 6% to 42% are reported to develop psoriatic arthritis[5], a painful and potentially debilitating type of arthritis. Patients with moderate to severe psoriatic arthritis are candidates for systemic treatment with immunosuppressant and biologicals.[6] However prevalence of psoriatic arthritis in Mauritian patients of psoriasis is not known.

Psoriatic arthritis (PsA) is the inflammation of the joints and the musculoskeletal system, in a patient of psoriasis with negative serology for rheumatoid factor.[1,2] No universally accepted gold standard exists for diagnosing PsA.[7] The criteria first proposed by Moll and Wright are currently the most frequently used, and includes an inflammatory arthritis, the presence of psoriasis and negative serology for rheumatoid factor.[8] Moll and Wright criteria for the diagnosis of Psoriatic arthritis does not include radiological findings. Using the criteria, PsA has been subdivided into five types, including oligoarticular, spondylitic, asymmetric polyarticular, distal interphalangeal and arthritis mutilans.

MATERIALS AND METHODS

An exploratory clinical research was carried out at the Skin Outpatient Department of a tertiary medical centre in Mauritius. A cross-sectional study of consecutive 55 patients of psoriasis of either sex was carried out by the

How to site this article: Yogesh M Shah, Bibi Kaushur D Khodaboccus. Psoriasis with psoriatic arthritis: A clinical study. *International Journal of Recent Trends in Science and Technology* November 2015; 17(1): 114-117 http://www.statperson.com (accessed 16 November 2015).

case study method from February 2011 to October 2012. A convenience sample of patients of psoriasis attending Skin Outpatient Department was taken, as source list of patients in the region, was not available.

Only patients of classical psoriasis of the skin were included in the study and the diagnosis of psoriasis was made on the following clinical criteria: 'Psoriasis vulgaris' if there was a typical clinical picture of well circumscribed, erythematous, scaly, chronic plaques on the scalp and the extensors, the 'Guttate psoriasis' if there was an abrupt eruption of typical psoriatic lesions of papular type; the 'Pustular psoriasis' if tiny sterile pustules were found on the surface of psoriatic plaques and the 'Psoriatic erythroderma' if extensive erythema and superficial scaling of more than 90% of the body surface occurred in a known case of psoriasis.[1,2]

The diagnostic criteria of Moll and Wright were used for the diagnosis of Psoriatic arthritis[8] which include the presence of inflammatory arthritis with psoriasis and with negative serological tests for rheumatoid factor. Joint swelling, redness, and deformity with restriction of movement of the joint, were recorded. Joints were categorized as distal interphalangeal joint (DIP), small joints of the hands, small joints of the feet, large joints and axial joints. Clinical types of psoriatic arthritis were divided in to five clinical types, as per the classification of Moll and Wright[8] : Isolated Distal interphalangeal joint (DIP) without any other peripheral joint involvement, Asymmetrical oligoarthritis (four or less joints involved), Polyarthritis (more than four joints involved), Spondylitis and Arthritis mutilans.

Patient of psoriasis in remission of skin lesions of psoriasis or a patient with isolated nail psoriasis or a patient of guttate psoriasis found to be serologically positive for VDRL or TPHA test were excluded from the study.

Following a detailed medical history and a clinical examination of each patient, the data was recorded in a comprehensive Case Record Form (CRF). Clinical photographs of selected cases and X-rays of hands, wrists, feet, cervical spine and lumbosacral spine were taken as per complaint of the patient and clinical findings.

The data collected was statistically analysed using SPSS16.0 (Statistical Package for the Social Sciences) software. The continuous data was described as mean and standard deviation. The categorical data was expressed as frequencies and percentages. Analysis of contingency tables was done by Fisher's Exact test. The categorical data was analyzed by Chi-squared test. A p value of < 0.05 was considered as statistically significant.

OBSERVATIONS AND RESULTS

A total of 55 patients were studied. Ethnically 52 (94.6%) patients were Mauritians of Indian origin and 3 (5.4%) patients were Mauritians of African origin. The age of patient ranged from 20 to 76 years and mean age was 48.9 years, SD is 13.5. Men were 36 (65.5%) and women 19 (34.5%). Male to female ratio was approximately 2:1.

A total of 14/55 (25.4%) patients of psoriasis were diagnosed to have Psoriatic arthritis.

Table 1: Gender and Psoriatic arthritis

Gender	Psoriatic arthritis	p value
Male	4 (28.6%)	p =0.002*
Female	10 (71.4%)	

* p< 0.05, Significant statistically

Psoriatic arthritis affected male to female in the ratio of 2:5. On performing the Fisher's Exact test, this finding was statistically significant ($p < 0.05$). Patients with scalp psoriasis were 22 (40%), flexural psoriasis 15 (27.2%), palmo-plantar psoriasis 4 (7.3%), nail psoriasis, 33 (60.0%) and psoriatic arthritis 14 (40.0%). Psoriasis vulgaris 53 (96.4%) and Guttate psoriasis 1 (1.8%). Limbs and the trunk were the commonest involved sites. Palms and soles were the least affected body sites. The duration of the skin psoriasis was 1-43 years, mean duration being 11.2 years ±SD 10.4. The duration of joint complaints was 1-25 years, mean duration being 7.3 years ±SD 7.1.

Table 2: Duration of Psoriasis of skin and that of joint involvement

	Duration of psoriasis of the skin				
	0-5 years	5-10 years	>10 years	TOTAL	p value
Psoriasis of skin	19 (34.5%)	14 (25.5%)	22 (40.0%)	55 (100.0%)	NS
Psoriatic arthritis	\3 (15.8%)	4 (28.6%)	7 (31.8%)	14 (25.5%)	NS

NS: Not Significant statistically

On comparing duration of psoriasis of the skin and joint involvement equal number of patients, 7 (50%) had joint involvement within 10 years or after 10 years duration of psoriasis of the skin.

Table 3: Clinical types of psoriatic arthritis. (n=14)

Type of Psoriatic arthritis	Patients
Symmetric Polyarthritis	3 (21%)
Asymmetric Polyarthritis	2 (14%)
Combination of Spondylitis and symmetric polyarthritis	4 (29%)
Oligoarthritis	4 (29%)
Classical Isolated distal inter-phalangeal joint of fingers	1 (7%)

Polyarthritis type of psoriatic arthritis occurred most frequently while Isolated Distal-inter-phalangeal joint type of Psoriatic arthritis was least frequent.

Table 4: Joints involved in Psoriatic Arthritis. (n=14)

Type of joints	Upper Limb	Lower Limb
Small Joints	(%)	(%)
▪ Distal inter-phalangeal	35.7	14.2
▪ Proximal inter-phalangeal	71	-
▪ Metacarpo-phalangeal and Metatarso-phalangeal jnts.	21.4	-
Large Joints		
▪ Wrist/Ankle	28.5	50
▪ Elbow/Knee	42.8	50
▪ Shoulder/Hip	35.7	7.1

Small joints of the upper limb were involved most frequently.

DISCUSSION

The estimated prevalence of psoriatic arthritis among psoriasis patients in the world literature ranges from 6% to 42%.[3,4] In this study the incidence of psoriatic arthritis among patients of psoriasis at a tertiary medical centre in Mauritius was observed to be 18.2%.

Table 5: Percentage of patients with Psoriatic arthritis in various studies

	This study	Bedi[9]	Saeed *et al.*[10]	Prasad *et al.*[11]
Number of patients	55	530	104	472
Joint involvement	18.2%	10.3 %	35%	8.5%

This wide range of prevalence of psoriatic arthritis could be due to influence of several factors such as environment, ethnicity, absence of standardized validated criteria and methodology in the studies.

In this study the Polyarthritis type of PsA was predominant, followed by Oligoarthritis and Spondilytis in equal frequency. The least frequent joint involvement was isolated DIP. Polyarthritis was also reported to be the commonest type of psoriatic arthritis, in an Indian study by Rajendran *et al*[12], and an Iranian study by Shariati *et al*.[13] Sadek *et al* from Egypt observed Spondylitis (64.4%) as being the most common type.[14] The Malaysian Annual report recorded more frequently the Oligoarthritis type.[15] Moll and Wright's paper also identified the Oligoarthritis type of joint pattern, as the commonest type.[8] Gladman *et al* inferred that more joints became involved as psoriasis progressed, hence polyarthritis pattern was more prominent.[16]

Half of patients in this study developed psoriatic arthritis within 10 years, and the remaining half, after more than 10 years of skin lesions. The association of psoriatic arthritis and duration of psoriasis of skin was statistically not significant. Psoriatic arthritis has been reported to occur within 10 years of duration of skin psoriasis.[8] One of the patients enrolled in the study had concurrent onset of joint involvement and skin lesions, while another patient reported having joint involvement 4 years prior to onset of skin lesions. Psoriasis arthritis can precede or appear simultaneously with skin psoriasis.[1]

The proximal-inter-phalangeal joints (PIP) of the fingers (71%) were observed to be most frequently involved, followed by the knee (50%) and the ankle joint (50%) in the study (Table 4). The report of joint most commonly affected by psoriatic arthritis differs: Rajendran *et al* reported the knee joint, Baker *et al*, the shoulder joint and Robert *et al*, the metatarsophalangeal joint (MTP).[11]

CONCLUSION

Among patients of psoriasis, Psoriatic arthritis was observed in about 1 out of 5 patients. It predominantly affected the female population as compared to males. The Polyarthritis type of Psoriatic arthritis was predominant. The proximal-inter-phalangeal joints (PIP) of the fingers were most frequently involved.

ABSTRACT

Background: The Quality of Life of a patient of psoriasis is similar to or worse than a patient of chronic diseases like ischemic heart disease, hypertension, diabetes and cancer, however no assessment of the same was available in Mauritius. Aim was to do a quantitative study of impact of psoriasis on the Quality of Life of the psoriatic.

Methods: A cross-sectional study of consecutive 55 patients of psoriasis was carried out at the Skin Outpatient department of a regional hospital in Mauritius. An assessment of impact of psoriasis on the Quality of Life of each patient of psoriasis was carried out using the Psoriasis Disability Index Questionnaire of A Y Finlay.

Results: Out of total 55 patients of psoriasis 30 (54.6%) had PDI score ≥ 20 and 25 (45.4%) patients < 20; 14/19 (73.70%) women had PDI score >20. (p value=0.024). The impact of psoriasis on the 'daily activities' of the psoriatic scored highest with (62.3%), followed by 'leisure' (39.2%), 'at work' (33.3%), 'treatment' (29.3%) and 'personal relationships' (8.1%).

Conclusions: The majority of the psoriatic had a severe negative impact on their Quality of Life which was most obvious in their 'daily activities' and in women.

Key words: Impact, Quality of Life, Psoriasis Disability Index, 'daily activities', women.

INTRODUCTION

Psoriasis is a disease characterized by systemic chronic inflammation with prominent involvement of skin, joints and the skeletal system. Emerging evidences demonstrate association of psoriasis with obesity, dyslipidaemia, hypertension, Diabetes mellitus Type 2, cardiovascular disease and the stroke.[1-4]

A psoriatic is also at an increased risk of psychiatric illness. National Psoriasis Foundation patient-membership survey of 6,194 patients with severe psoriasis revealed that 79% considered psoriasis had a negative impact on their quality of life.[5] The severity of the negative impact on QOL can be gauged from another study of 138 patients in which 7.2% reported thoughts of suicidal ideation.[6]

Quality of Life (QOL) is the term used to describe a person's emotional, social and physical well-being.[7] Among psoriatic, QOL is found to be similar to or worse than chronic diseases like ischemic heart disease, hypertension, diabetes and cancer.[8,9] During the past decade, dermatologists have taken much

interest in quantification of Quality of Life among skin patients to the benefit of patients, clinicians and ultimately decision makers.

Psoriasis affects the individual in all spheres of his life. For a psoriatic 'daily activities' like sleeping, walking, sitting and doing household chores or shopping might become difficult.[10,11] A psoriatic may dress differently to conceal the lesions of psoriasis, may change dress and bathe more frequently.[10] A psoriatic may be denied use of public facilities like swimming pools, health clubs and hair salons.[12]

The disabling nature of the disease restricts a psoriatic from practicing sports[10] and in selection of the career.[13] The work life and career of a psoriatic is affected as one has to take leave due to the disease and its treatment; earning capacity and productivity of the individual may also be reduced.[13]

Disease perception by spouse, family members, relatives and friends could make a psoriatic feel embarrassed or humiliated affecting the relationships and this may lead to depression and suicidal ideation.[6,8]

Psoriasis Area and Severity Index, is a measure of severity of psoriasis and is not directly related to the QOL. The Psoriasis Disability Index (PDI) and the Dermatology Life Quality Index Questionnaire are commonly used quantitative measures of impact on QOL of a psoriatic.[14] The PDI has been used in 20 different countries during the past two decades and is composed of 15 questions covering the disability in 'daily activities', 'at work', 'personal relationship', 'leisure' and 'treatment'.[15]

Aim was to make a quantitative study of the impact of psoriasis on Quality of life of the psoriatic.

METHODS

A cross-sectional study of consecutive 55 patients of psoriasis was carried out at the Skin outpatient department of a Regional Hospital in Mauritius from February 2011 to October 2012. An approval of the Regional director of the hospital and an informed consent of the patient were obtained for the study. A convenience sample of patients of psoriasis attending Skin Outpatient Department was taken as source list of patients in the region was not available.

A clinical diagnosis of 'psoriasis vulgaris' was made on the basis of a typical clinical picture of well circumscribed, erythematous, scaly, chronic plaques on the scalp and the extensors. A diagnosis of the 'guttate psoriasis' was made in case of abrupt eruptions of typical psoriatic lesions of papular type, 'pustular psoriasis' if tiny sterile pustules were found on the surface of a psoriatic plaque and 'psoriatic erythroderma' if extensive erythema and superficial scaling of more than 90% of the body surface occurred in a known case of psoriasis.[16,17] The clinical data about psoriasis and co-morbidities like obesity, hypertension, diabetes mellitus and cardiovascular diseases were collected.

Patient of psoriasis in remission of skin lesions of psoriasis or with isolated nail psoriasis or the guttate psoriasis found to be serologically positive for VDRL or TPHA test were excluded from the study.

The impact of psoriasis on Quality of Life of the psoriatic was studied using a disease specific 'Psoriasis Disability Index (PDI) Questionnaire' of A.Y.Finlay[15]. A written permission for the use of the said 'Psoriasis Disability Index questionnaire (PDI)' was obtained from Prof. A.Y. Finlay. A tick box system was used in the questionnaire for simplicity and clarity in the scoring.[10,15]

The questionnaire contained a total of fifteen questions, covering difficulty encountered under five different subsections during the previous 4 weeks. The five subsections were: daily activities, at work, personal relationships, leisure activities and treatment. A score from 0 to 3 was given in response to every question. The choice for each question was 'very much' (scored 3), 'a lot' (scored 2), 'a little' (scored 1), 'not at all' or no answer (scored 0).

The 'daily activities' section had 5 questions with a maximum score of 15, 'at work' 3 questions with a maximum score of 9, 'at leisure' 4 questions with a maximum score of 12, 'personal relationship' 2 questions with a maximum score of 6 and 'treatment' 1 question with a maximum score of 3. The maximum score for the whole questionnaire could be 45 and minimum 0. The total PDI scores were put in two categories: patients with total PDI score of < 20 and patients with total PDI score of ≥ 20.

Data Analysis: The data obtained was recorded in a comprehensive Case Record Form (CRF) and statistically analysed using SPSS 22 (Statistical Package for the Social Sciences) software. The continuous data was described as mean and standard deviation. The categorical data was expressed as frequencies and percentages. Analysis of contingency tables was done by Fisher's Exact test. The categorical data was analyzed by Chi-squared test. A p value of < 0.05 was considered as statistically significant.

RESULTS

A total of 55 patients of psoriasis were subjected to the 'Psoriasis Disability Index' Questionnaire. The age of patients of psoriasis ranged from 20 to 76 years and the mean age was 48.85 years, ± SD 13.49;

36 (65.5%) patients were men and 19 (34.5%) patients women; 34 (61.8%) married, 11(20%) single, 7 (12.7%) widowed and 3 (5.5%) divorced; 25 (45.5%) employed and 18 (32.7%) patients unemployed. A total of 14 (25.4%) patients had psoriatic arthritis.

The minimum Psoriasis Disability Index (PDI) score recorded was 0 and maximum 39, the mean PDI score was 21.25 ± SD 10.5.

The PDI score was greater than or equal to 20 in 30 (54.6%) patients and less than 20 in 25 (45.4%) patients.

PDI score and the gender were associated significantly. (p value=0.024) Larger percentage of Female patients was seen with greater PDI score.

The highest PDI score (indicating the greatest disability) was recorded in 'Daily activities', followed by 'Leisure activities', 'At work' and 'Treatment'. "Personal relationship" scored the least. The maximum score in the 'Daily activities' subsection in the PDI questionnaire was 15/15 and minimum 0. The mean score was was 9.35 with SD 4.4. The maximum score in 'At work' subsection was 9/9 and minimum 0. The mean score was 3.95 with SD 3.6. No significant statistical association was found between patients who were unemployed and those who had a job.

Table 1: PDI* score and frequency

PDI score	Patients (%)
<10	8 (14.5)
10 -19	17 (30.9)
20 - 29	14 (25.5)
>=30	16 (29.1)
Total	55 (100)

*Psoriasis Disability Index

Table 2: PDI score in male and female.

Gender	PDI score groups		Total
	< = 20	> 20	
Male	21 (58.30)	15 (41.70)	36 (100)
Female	5 (26.30)	14 (73.70)	19 (100)
Total	26 (47.30)	29 (52.70)	55 (100)

Table 3: Total score in each subsection of the PDI questionnaire

PDI score	Patients (%)
Daily activities	62.3
At work	33.3
Personal Relationship	8.1
Leisure	39.2
Treatment	29.3

*Psoriasis Disability Index

Table 4: Details of responses to questions pertaining to the impact on 'Daily activities', 'Work' and 'Leisure activities' subsections of the PDI Questionnaire

	No answer	Very much	A lot	A little	Not at all	Total
Daily Activities						
Work around the house or garden	0 (0)	27 (49.1)	8 (14.5)	6 (10.9)	14 (25.5)	55 (100)
Types or colors of clothes	0 (0)	45 (81.8)	1 (1.8)	4 (7.3)	5 (9.1)	55 (100)
Change or wash clothes	0 (0)	39 (70.9)	3 (5.5)	3 (5.5)	10 (18.2)	55 (100)
Problem at hairdresser	4 (7.3)	18 (32.7)	2 (3.6)	5 (9.1)	26 (47.3)	55 (100)
More Baths	0 (0)	29 (52.7)	4 (7.3)	4 (7.3)	18 (32.7)	55 (100)
At work						
Time off work	0 (0)	22 (40)	4 (7.3)	5 (9.1)	24 (43.6)	55 (100)
Problem at work	0 (0)	24 (43.6)	5 (9.1)	3 (5.5)	23 (41.8)	55 (100)
Career affected	0 (0)	19 (34.5)	2 (3.6)	0 (0)	34 (61.8)	55 (100)
Leisure activities						
Stopped going out socially	1 (1.8)	22 (40)	6 (10.9)	6 (10.9)	20 (36.4)	55 (100)
Difficulty in doing sports	1 (1.8)	14 (25.5)	5 (9.1)	5 (9.1)	30 (54.5)	55 (100)
Stopped using communal facilities	5 (9.1)	28 (50.9)	3 (5.5)	4 (7.3)	15 (27.3)	55 (100)
Smoking and Drinking alcohol	3 (5.5)	7 (12.7)	1 (1.8)	0 (0)	44 (80)	55 (100)

Figure in parenthesis indicate percentage

The maximum score in 'Leisure activities' subsection in the PDI questionnaire was 12/12 and minimum 0. The mean score was 4.7 with SD 3.5. Only 8 (22.2%) male patients had reported that they were not at all affected by psoriasis; rest of the male patients and all the female patients were affected (that is answered as either 'very much', 'a lot' or 'a little').

The maximum score in the 'personal relationships' subsection in the PDI questionnaire was 6/6 and minimum 0. The mean score was 0.56 with SD 1.1. This subset had the least scores. Only 7% of patient had responded to 'very much' for the two questions; 24 % of patient did not respond to the question on sexual difficulties. No statistical significant association could be seen between divorced, single patients with patients who were married.

The maximum score in 'Problem with Treatment' section in the PDI questionnaire was 3/3 and minimum 0.The mean score was 2.25 with SD 1.1; 34 patients (61.8%) were very much affected by the treatments and about 10 patients (18.5%) marked the 'a lot' tick box.

In this study among male patients 20/36 (55.6%) had PDI scores ≤ 20, and among female patients 14/19 (73.6%) had PDI scores > 20. The association between PDI and gender was statistically significant. (p value 0.024). The complaint of pruritus was present in 32 (58.2%). No statistically significant association between pruritus and episodes of exacerbation, severity of disease (BSA) and total PDI score could be established.

The most frequent co-morbidities reported were Obesity 28 (54.6%), Diabetes Mellitus Type II 18 (32.7%) followed by Hypertension 14 (25.4%), and Cardiovascular disorders 7 (12.7%). Following diseases were reported in 41 (74.5%) patients. They were Vitiligo, Bronchial asthma, Hepatitis C, Diabetes mellitus Type I, Transient ischaemic accident, Adenocarcinoma of colon and Depression. Limbs and the trunk were the commonest involved body sites. Psoriasis vulgaris was the clinical type observed in 53 (96.4%), guttate psoriasis in 1 (1.8%) and psoriatic arthritis in 14 (40.0%).

DISCUSSION

The mean PDI (Psoriasis disability index) score of a patient of psoriasis in the study, was 20.84 ± SD 10.4 with a maximum 39. The score in this study was twice than that of an Indian study and a European-survey.[18,19] In a cluster analysis of 50 patients in India, the authors recorded a mean total PDI score of 9.38 with a maximum score of 48.[18] A modified scoring was adopted by the author and the questionnaire had 16 questions with a maximum score of 48.[18]

The impact on QOL in this study, was highest in subset "daily activities" (score 62.3%), followed by "leisure activities", "at work", "treatment" and least in the "personal relationship".

A study in Kerala observed that QOL was most affected in the subset "daily activities" (90.6%), followed by work (84.4%), leisure (71.9%), problems with treatment (68.7%) and the personal relations (62.5%).[20] According to the EUROPSO survey, 48% of reported problems were related to activities of 'daily living' and less disability was reported in employment, personal relationships, and behaviour (smoking or drinking).[19]

Patients paid particular importance to the type and colour of clothing to conceal psoriatic lesions, 81.8% patients had responded as affected "very much" to this question. Patients reported wearing long sleeved clothes and preferred trousers or long dresses or skirts while going out. The psoriatic patients also reported using pale colours, as the scales were more prominent on dark coloured clothes. Rakhesh et al[21] and the EUROPSO survey[19] also reported a high response rate for the questions on clothes and baths. It was observed that questions pertaining to the impact on choice of clothing and need for frequent change or washing were mostly answered by 'a lot' or 'very much' like other studies and surveys.[11,20,21] Problems at the hair dresser scored least in this study. Patients reported that they usually did not visit the hairdresser but preferred to do the haircut themselves at their home.

The impact on the QOL of the psoriatic in the "daily activities" is unanimously confirmed.[11,18,20,21]

In this study, 45.5% of patients were employed. Nearly half of the patients found psoriasis to be a problem 'at work' and lost time off work, 38% of patient reported their career to be affected. Few patients had to change their jobs due to the disease. They opted for careers where they were not in direct contact with the public; 32.7% of psoriasis patients were unemployed and they related psoriasis as the cause of unemployment, this was statistically not significant. Manjula et al[20] reported that 84.4 % of patients psoriasis were affected 'at work'. The career seemed to be less affected as per Dubertret et al and Rakhesh et al.[19, 21]

It should be noted that 24% of patients did not respond to the question on 'sexual difficulties', hence scored 0 for the unanswered question. Cultural reluctance to answer this question or merely the fact that 42.7% of patients were single, widowed or divorced could be the reason for the poor response rate to this question. The survey carried out in European countries has reported that more than a quarter of respondents were significantly affected within sexual relationships.[19]

In the Mauritian context, the communal facilities commonly used are the public beaches. More than half of the patients responded to the question pertaining to it by answering affected "very much". Few reported going to beaches early morning when the visitors would be scarce. More than half of the patients avoided social events; 40% had responded by answering affected "very much" and 10.9% "a lot". Similar findings were noted by Rakhesh et al.[21]

In this study 25.5% of the patients found it "very much" difficult to practice any sports mainly due to pain and disability due to the disease. In contrast, Rakhesh et al reported a much lower impact on sports activities and related their findings to the cultural differences and the life style.[21]

Majority of the patients in the study (61%), found the treatment very messy; consistent with findings by Manjula et al. from Kerala.[20]

CONCLUSION

Psoriasis caused a severe negative impact on the Quality of Life in majority of the patients. The majority of women had a severe disability unlike men. The negative impact due to psoriasis was greatest on "daily activities', followed by "leisure activities", "at work", and the "personal relationship" of the patient. Majority of the patients of psoriasis had "problems with treatment" as it was "very messy."

ACKNOWLEDGEMENTS

We are thankful to the Regional Health Director of J. N. Hospital, Rosebelle, Mauritius, the Ministry of Health and Quality of Life, Government of Mauritius and the Director, the Dean, the Head of Department, Dept. of Dermatology, Dr D Y Patil Medical College, Mauritius, for facilitating the above study.

A Prospective Study on Bacteriological Profile of Skin and Soft Tissue Infections with it`s Antimicrobial Sensitivity Pattern in a Tertiary Care Hospital

Ajit Singh

Assistant Professor, Department of Skin & VD, AIMS & RC, Udaipur.

ABSTRACT

Background: *SSTIs are the most common cause of morbidity in community and hospital.1 the most common examples of SSTIs are cellulitis, abscesses, impetigo, folliculitis, furuncle, carbuncle, necrotizing fasciitis , diabetic foot infections and surgical site infections .*
Methods: *In this study we were included 207 cases of skin & soft tissue infection. Among all 134 cases have positive bacterial growth which we were considered. This study conducted in Department of skin with collaboration of Department of Microbiology.*
Results: *We seen 47.1% growth of Staphylococcus aureus followed by Enterococcus spp. While in gram negative bacteria we seen 24.6% growth of Klebseilla followed by Pseudomonas aeruginosa & Escherichia coli.*
Conclusions*: Local antibiotic policy can be adopted which will prevent resistance among organisms and help in early recovery from infection.*

INTRODUCTION

It is well known that skin and soft tissue infections (SSTIs) are a common type of infection. It may contribute to longer hospital stays, increase the cost of medical care. It also plays an important role in development of antimicrobial resistance. SSTIs are the most common cause of morbidity in community and hospital.1 the most common examples of SSTIs are cellulitis, abscesses, impetigo, folliculitis, furuncle, carbuncle, necrotizing fasciitis, diabetic foot infections and surgical site infections. Some infections can be treated by oral antibiotics. Complicated SSTI may require hospitalization, intravenous antibiotic and or surgery. An SSTI is categorized as complicated if the infection has spread to the deeper soft tissue, if surgical intervention is necessary or if the patient has comorbid conditions hindering treatment response.[1,2] SSTIs may be caused by many pathogens. Staphylococcus aureus is salvaged from maximum number of SSTIs. Other organisms recovered are Pseudomonas aeruginosa, Escherichia coli, Enterococcus, Klebsiella and Enterobacter species.[2,3-6] It is crucial to monitor the changing trends in bacterial infection and their antimicrobial susceptibility pattern to provide adequate antimicrobial therapy for controlling infection, preventing morbidity and improve the quality of life.

Though, the most common organism causing wound infections was Staphylococcus aureus followed by other Gram-negative bacilli,[7] but in India Gram negative bacilli was predominantly isolated compared to Gram-positive pathogens.[8,9] These infections are difficult to treat due to increasing antibiotic resistance.[8] The arbitrary use of

antibiotics has also lead to the increase in multidrug resistant organisms (MDRO).[9] Now a days, infections are the leading cause of morbidity in patients of surgery, trauma etc.[10] For proper management of the patients, it is important to know the pathogens causing the infections and its antibiotic susceptibility.[11]

Previous studies provided very limited data on soft tissue infection, mortality rate and antibiotic susceptibility of Gram negative bacilli in our hospital settings. Therefore, the present study was undertaken to determine the aerobic bacteriological profile from various type of wound infections and the susceptibility pattern of the isolates.

METHODS

Study population:- In this study we were included 207 cases of skin & soft tissue infection. Among all 134 cases have positive bacterial growth which we were considered.

Study area:-This study conducted in Department of skin with collaboration of Department of Microbiology.

Study duration:- The duration of this study was over a period of one year.

Data collection:- First samples were inoculated on to Blood agar and MacConkey agar . Then samples were subjected to gram stain of direct smear to examine for the presence of pus cells and any bacteria. Culture plates were incubated at 37degree Celsius for 24hrs to 48hrs in aerobic condition. If there was no growth it was considered sterile. After incubation ,identification of bacterium from positive cultures was done with a standard microbiological technique which includes motility testing by hanging drop preparation ,gram staining and biochemical reactions such as catalase, coagulase, indole, methylred, Voges-Proskauer, citrate, urease, Phenyl pyruvic acid test and oxidase test(6).Further biochemical tests done were carbohydrate fermentation test using Lactose, sucrose, mannitol & Maltose, Triple sugar Iron test, Nitrate reduction test, Arginine dihydrolase production, lysine and ornithine decarboxylase test, Hugh and leifson test. The antimicrobial susceptibility testing was done by Kirby Bauer Disk Diffusion method and interpreted as per Clinical Laboratory Standard Institution (CLSI) guidelines

Data analysis:-Data were analysed by using Microsoft excel.

RESULTS

In this study we were screened 207 cases. Among all cases 134 cases have got positive culture & rest were no growth. In our study we found that 50.7% growth of gram-positive bacteria & 49.3% growth of gram negative. Among gram positive growth we seen 47.1% growth of Staphylococcus aureus followed by Enterococcus spp. While in gram negative bacteria we seen 24.6% growth of *Klebseilla* followed by Pseudomonas aeruginosa & Escherichia coli. Antimicrobial susceptibility pattern we also observed in this study which showed in chart:1,2,3,4.

Table 1: Distribution of cases according to culture growth

Culture growth	No. of cases	Percentage
Negative	73	35.2
Positive	134	64.8
Total	207	100

DISCUSSION

In the present study, the prevalence of culture positive samples is 64.73%. Similar results were found by Hanumanthappa P et al[12] and Sah P et al.[13] This study observed the domination of Gram-positive organisms which comprises 50.75%. These findings were supported by Sah P et al.[13] Though studies done by Afroz Z et al,[14] Najotra K et al,[15] Madhavi S et al[16] showed domination of Gram-negative isolate. The most common organism isolated in our study is Staphylococcus aureus. Similar findings were found by Najotra K et al,[15] Hanumanthappa P et al[12], Sah P et al[13] and Madhavi S et al.[16] Results also showed that among the Gram-negative organisms, the most common isolate is Klebsiella species. Hanumanthappa P et al[12] also reported the similar findings. However, in Afroz Z et al[14], Najotra K et al.[15]

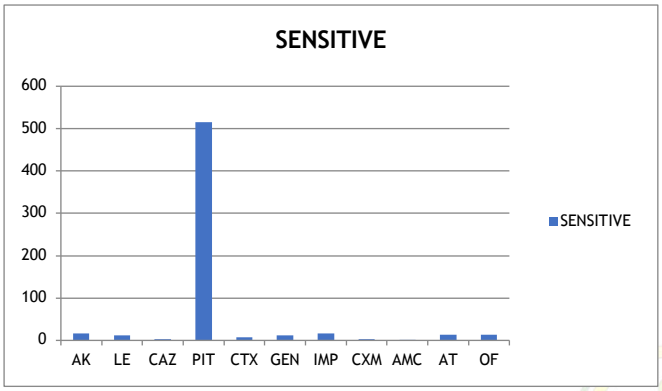

Chart:-4 Sensitivity pattern of Pseudomonas aeruginosa

Mishra D et al[17] studies, the most common isolate is Pseudomonas and in Sah P et al the most common isolate is Escherichia coli.

Staphylococcus aureus is 100% sensitive to Vancomycin and Linezolid in this study. Similar finding was found in Mishra D et al**,** Najotra K et al**.** While Sah P et al found only 5.56% Vancomycin resistance in their study. Staphylococcus aureus is least sensitive to Amoxycillin/ Clavulanic acid in our study. In contrary, a study conducted by Madhavi S et al[16] Staphylococcus aureus showed maximum resistance towards Ampicillin. The prevalence of MRSA is 28.57% in this study. Similar finding was found by Mishra D et al. However, Rani S et al,[18] Shetty J et al[19] showed low prevalence of MRSA in their study.

In the present study, the most common organism among Gram negative isolates is Klebsiella species. Klebsiella showed highest susceptibility towards Imipenem and maximum resistance towards Amoxyclav. Mohanty S et al[20] found Klebsiella has the maximum sensitivity towards Piperacillin/ Tazobactum and maximum resistance towards Piperacillin. While Sah P et al observed Klebsiella has maximum susceptibility towards Ciprofloxacin and maximum resistance towards Cefepime and Amoxycillin. Therefore, the antibiotic susceptibility pattern of Klebsiella changed in different studies.

It can be concluded that the most common organism causing skin and soft tissue infections is Staphylococcus aureus followed by Klebsiella.

The study also observes a rise in prevalence of MRSA. Though, a changing pattern were observed among the organisms isolated as well as their antibiotic sensitivity pattern in several studies from different geographical locations.

CONCLUSION

This study concludes that it is important to conduct repeated monitoring of antibiotic susceptibility pattern to reduce the increasing trend of antimicrobial resistance. Additionally, a local antibiotic policy can be adopted which will prevent resistance among organisms and help in early recovery from infection. The study stresses on appropriate and judicious use of antibiotics.

A Prospective Study on Dermatological Manifestations in Type 2 Diabetes Mellitus Patients

Ajit Singh
Assistant Professor, Department of Skin & VD, AIMS & RC, Udaipur.

ABSTRACT

Background: *Diabetes mellitus is a major health problem with increasing numbers. Globally, it has been estimated that the prevalence of DM among all age groups is about 2.8% in the year 2000 and will reach up to 4.4% by the year 2030. In developing and underdeveloped countries, the prevalence will rise from 4.2% to 5.6%.*
Methods*: Total 200 cases were included in this study. Among all 118 cases were infective and rest were non-infective. This study was conducted in Department of Dermatology. The duration of study was over of period of one year.*
Results*: Among 200 cases 56% cases were male rest were female. Out of 200 cases 118 cases are infective and 82 cases are non-infective. In this study we studied 61.1% cases of fungal infection followed by 30.5% bacterial cases, 6.7% of viral cases & 1.6% cases of parasitic infection.*
Conclusions*: The manifestations should be actively sought in all diabetic patients because early diagnosis and management can reduce morbidity.*

Key words*: Diabetes mellitus, Bacterial infection, fungal infection*

INTRODUCTION

Diabetes mellitus is a metabolic disease. It is characterized by hyperglycaemia. It occurs due to defects in insulin secretion or insulin action or a combination of both.[1] Infections occur frequently in diabetes mellitus patients and their presence can trigger acute metabolic complications.[2] The long-term complications of diabetes mellitus have adverse effects on both the cellular and humoral immune systems. For example, the chemotactic function of polymorphonuclear leucocytes is weakened in patients with diabetes.[3] In diabetic patients, many abnormalities might contribute to the higher susceptibility and severity of infections for example, reduced mastocyte function, lower neutrophil chemotactic activity, reduced leucocyte numbers in inflammatory lesions, low oxidant molecule production, decreased lymph node retention capacity and reduced cytokine release.[4-7] Diabetes mellitus is a major health problem with increasing numbers. Globally, it has been estimated that the prevalence of DM among all age groups is about 2.8% in the year 2000 and will reach up to 4.4% by the year 2030. In developing and underdeveloped countries, the prevalence will rise from 4.2% to 5.6%.1 Skin being the largest organ of the body also gets badly affected by both acute metabolic derangements and chronic degenerative complication of DM.[8,9] Several factors are involved in manifestation of dermatological signs of DM. Derangement

DOI: 10.21276/iabcr.2017.3.3.32	

in carbohydrate metabolism, changes metabolic pathways in the patients which leads to display of the disease in various forms involving all the systems of the body. The incidence of cutaneous disorders is mostly observed than the manifestations of the disease in other systems of the body. Dermatological signs of DM are generally seen once the disease develops; at times they may precede the development of the disease and can give a clue of the impending metabolic disorder. Some skin manifestations are caused by direct metabolic changes arising due to hyperglycaemia and lipid abnormalities. Whereas several other complications are caused by vasculopathies, neuropathy or immunological.[10,11] most of the subjects had a history of DM of over 10 years, and all these subjects had dermatological manifestations. It can be assumed that with increasing duration of illness the complications tend to rise. It is due to the development of advanced glycated products that are formed no enzymatically causing cutaneous damage.[12,13]

METHODS

Study population:- Total 200 cases were included in this study. Among all 118 cases were infective and rest were non-infective.

Study area:- This study was conducted in Department of Dermatology.

Study duration:- The duration of study was over of period of one year.

Data collection:- Informed consent was obtained. A detailed history was elicited with particular reference to cutaneous complaints and including details regarding duration, history of evolution, progression and treatment modalities. Clinical examination included general physical examination followed by a meticulous examination of the lesion done to make a diagnosis and investigations such as 10% KOH smear where required. Control of Diabetes was assessed by available HbA1c levels, FBS, PPBS levels.

Data analysis:- Data were analysed by using Microsoft excel.

RESULTS

In this study we were involved 200 cases. Among 200 cases 56% cases were male rest were female. Out of 200 cases 118 cases are infective and 82 cases are non-infective. In this study we studied 61.1% cases of fungal infection followed by 30.5% bacterial cases, 6.7% of viral cases & 1.6% cases of parasitic infection. In the fungal cases 46 cases of candida infection and rest were dematophytic infection found. Among the camndidal infection 65.2% were found of intertrigo ,26.6% cases of Candidal Balanophosthitis and 8.6% of Vulvovaginal Candidiasis. While in dematotophytic cases we found 30.7% cases of Tinea corporis followed by other cases. In 44.5% cases of Furunculosis we seen while 22.3% cases of Folliculitis & abscess, 5.5% cases of Carbuncle & Cellulitis were found.

Tinea pedis	2	7.6
Tinea corporis	8	30.7
Tinea incognito	6	23.1
Tinea cruris	6	23.1

DISCUSSION

In the present study, the most common age group of diabetic patients with cutaneous manifestations is between 46-55 years. While in Mashkoor ahmed et al study the age group

was 51- 60 years.[14,15] The female predominance was found in our study. Similar findings were found by Mashkoor ahmed et al Mahajan et al and Romano et al.[16,17] Ahmed et al also showed that skin diseases 19 were more common in women than in men. In contrast Binkley[18] and Danowsky et al observed a higher incidence of cutaneous diseases among male diabetics. Sargodha also conducted a study and found skin disorders more in men than women.[19]

Results of this study also showed that cutaneous infections were the most common cutaneous manifestations in 59% of the cases, Similarly, Nigam and Pande and Ahmed et al[16] found cutaneous infections to be the most common dermatoses in their studies. The reason behind higher incidence of cutaneous infections in diabetes may be related to abnormal microcirculation, hypohidrosis, peripheral vascular disease, diabetic neuropathy, decreased phagocytosis, impaired leukocyte adherence, and delayed chemotaxis.[20,21] This study also found the cutaneous fungal infections as the most common infection. It was observed in 61.01% of the cases[22], followed by bacterial infections in 30.5%[17] and viral 6.77%[23] and parasitic 25 1.69%.[24] These findings were supported by Dependra et al. Among the non-infective dermatosis Pruritus and xerosis were the second most common manifestation. It was seen in 17.07% patients. Generalized pruritus is not precisely related with diabetes mellitus, though pruritus vulvae and[21] balanitis may be the presenting symptoms of diabetes . In elderly diabetics, itching could be a manifestation of xerosis. Pruritus[15] was also the second most common finding in Mahajan et al's[25] study. Rao and Pai also showed that pruritus was the main presenting symptom and was seen in 60.23% patients in their series. Diabetic patients can present with array of cutaneous disorders. Cutaneous infections formed the largest group of dermatoses in our study. Higher incidence of cutaneous infections mainly fungal and bacterial was observed in majority of the uncontrolled diabetics, this condition emphasizes the need for more aggressive management of diabetes mellitus. Among infective dermatoses, fungal infections were the most common than dermatophytosis. Other commonly observed dermatoses were pruritus without any skin lesions, xerosis, prurigo, achrochordon, acanthosis nigricans, granuloma annulare, seborrhoic keratosis. There are multiple factors for cutaneous manifestations of diabetes mellitus. These are abnormal carbohydrate metabolism, microangiopathy, atherosclerosis, neuron degeneration and impaired host defense mechanisms.

Table 5: Distribution of cases according to bacterial infection

Bacterial infection	No. of cases	Percentage
Folliculitis	8	22.3
Furunculosis	16	44.5
Abscess	8	22.3
Carbuncle	2	5.5
Cellulitis	2	5.5

CONCLUSION

The manifestations should be actively sought in all diabetic patients because early diagnosis and management can reduce morbidity.

ABSTRACT

Background: Acne is a chronic inflammatory disease of the pilosebaceous unit, mainly affecting face and frequently followed by scarring. It is the most common skin disease in an urban dermatology clinic in India. Adult acne is more common in women and may be a marker of hyperandrogenism. The present study was carried out to study the clinical profile of acne vulgaris in semiurban patients.
Methods: The study was conducted for 1 year on all eligible patients of acne vulgaris attending dermatology OPD of a hospital catering to semiurban patients. Data including grade of acne, markers of androgenicity and post-acne scarring was collected. Statistical analysis was done using SPSS 15 software.
Results: Frequency of acne vulgaris patients in the dermatology OPD was 2.8% with 429 acne patients out of 15,322 new patients. Female to male ratio was 1.44:1. The mean age of onset in males was 16.24 and in females, 14.84 years. Grade 2 acne (66%) was commonest followed by grade 3 (5.1%) and grade 4 (3.7%). Associated conditions seen were seborrhea (60.8%), alopecia (18.9%), acanthosis (4.9%) and PCOD (2.3%). Markers of androgenicity were more frequently seen in grade 2 acne which was statistically significant. Atrophic scars were commonest including icepick scars (80.2%), rolling scars (67.4%) and box scars (57.8%).
Conclusions: In our study females had an earlier onset and closed comedones were the most common acne lesion. Grade 2 acne vulgaris formed majority of patients. Grade 4 acne vulgaris was more common in males.

Keywords: Acne vulgaris, Semiurban, Clinical profile, Markers of androgenicity, Scarring

INTRODUCTION

Acne is a chronic inflammatory disease of the pilosebaceous units; it is characterized by seborrhoea, the formation of open and closed comedones, erythematous papules and pustules and in more severe cases nodules, deep pustules and pseudocysts. Inflammatory lesions are followed by scarring.[1] It is stated that 90% of individuals, male and female, between puberty and age of 30 years, experience some degree of acne and is reported by Kubba et al to be the most common skin disease, in an urban dermatology clinic in India. There are estimated 200-300 million acne sufferers in the country.[2]

Acne vulgaris develops earlier in females than in males. Occasionally, it may start at age 7 or 8 years (adrenarche) and when it does, it portends severe acne. Less commonly, acne may make its first appearance in mature adults- after 25 years of age (adult acne). Adult acne is more common in women and is often, a part of cutaneous hyperandrogenism. Acne waxes and wanes through adolescent years and early adult life, rarely it may persist

well into the fifth and the sixth decade (persistent acne). The most severe forms of acne vulgaris occur more frequently in males, but the disease tends to be more persistent in females. Severity of the disease varies markedly from one individual to the other depending upon the interplay of various factors involved in the development of acne vulgaris.[1-4]

Acne may ruin beauty and it may result in scars for life. Sufferers often have significantly impaired psychological development. The patient develops reduced self- esteem, and reduced career prospects caused by perceived disfigurement. These effects can be less related to the severity of the disease than to the patient's own perception.[2,5]

The present study on acne vulgaris was carried out to study age of onset, gender predilection, body site involved, severity, association of seborrhea, alopecia, and markers of androgenicity in females.

METHODS

A cross sectional, observational study on acne vulgaris was conducted between January 2011 to December 2011 in the dermatology outpatient department of a medical college hospital at Lucknow, after obtaining permission of Institutional Ethics Committee. A total of 429 consecutive, eligible patients of either gender were included as subjects. Acneiform eruptions, drug and cosmetic induced acne were excluded.

The data was collected in a predesigned case record form which included age, gender, marital status, age of onset, duration of acne, body site involved, number and severity of acne lesions, relation to menstrual cycle, markers of androgenicity, post-acne hyperpigmentation and scarring. The severity of acne vulgaris was graded into four grades using a simple grading system, taking into account the predominant lesion.[6]

- Grade 1: Comedones, occasional papules
- Grade 2: Papules, comedones, few pustules
- Grade 3: Predominant pustules, nodules, abscesses
- Grade 4: Mainly cysts, abscesses, widespread scarring

Statistical analysis was done using SPSS 15 software (SPSS, Chicago, IL, USA).

RESULTS

A total of 15,322 new patients attended the dermatology OPD, during the study period of one year, 429 patients presented for acne vulgaris, giving a frequency of 2.8%.

A total of 253 (59%) were females and 176 (41%) were males, giving female to male ratio of 1.44:1. Mean age of male patient was 19.20 (±3.16) years and female 21.68 (±4.29) years (Table 1). All male and 90.9% of female patients were unmarried.

Table 1: Age wise distribution.

Age in years	Male	Female
	No.	**No.**
10-15	21	16
16-20	101	100
21-25	47	85
26-30	7	47
>30	0	5
Total	176	253

X^2=33.1; p<0.001

Table 2: Age of onset of acne vulgaris.

Age onset	Male (n=176) (%)	Female (n=253) (%)
10-15	64 (36.4)	176 (69.6)
16-20	105 (59.6)	76 (30.0)
21-25	7 (4.0)	1 (0.4)
Mean±SD	16.24±2.05	14.84±1.58

X^2=49.18; p<0.0001.

Age of onset in 240 (55.9%) patients was between 10 to 15 years of age, with a mean of 15.41 (±1) years. Age of onset in males 105 (59.6%) was between 16 to 20 years of age, with a mean of 16.24 (±2.05) years; age of onset in females was 176 (69.6%) between 10-15 years of age, at the mean age of 14.84 (±1.58) years (Table 2). Family history of acne was observed in 225 (52.5%) patients.

In a majority (40.3%) of patients, the total duration of acne, was more than 60 months. The duration of acne ranged from 1 week to 24 years, with an average duration of 39.81 months. Out of a total of 286 (66.7%) patients, 186 (43.4%) patients complained of itching and post inflammatory hyper pigmentation. A total of 204 (80.6%) female patients gave history of habitual picking of acne, as compared to 122 (69.3%) male.

The mean age of menarche was 13.99 (±1.80) years. Menstrual cycle was regular in 73 (28.9%) patients. History of premenstrual flare was present in 159 (37.2%) patients.

Table 3: Body site affected.

Site of acne lesions	No (n=429) (%)
Face	429 (100)
Arms	83 (19.3)
Back	110 (25.6)
Chest	75 (17.5)
Neck	32 (7.5)

A total of 288 (67.1%) patients presented with acne of 'face alone.' As such face was involved in all (100%) patients, followed by back 110 (25.6%), arms in 83

(19.3%), chest 75 (17.5%) and neck in 32 (7.5%) patients (Table 3).

Table 4: Morphology of lesions.

Types of lesions	No (n=429) (%)
Open comedones	223 (52)
Closed comedones	416 (97)
Papules	321 (74.8)
Pustules	112 (26.1)
Nodules	38 (8.9)
Abscesses	29 (6.8)
Pseudocyst	16 (3.7)

Closed comedones were observed in 416 (97%) patients had, followed by papules in 321 (74.8%), open comedones in 223 (52%), pustules in 112 (26.1%), nodules in 38 (8.9%), abscesses in 29 (6.8%) and pseudocyst in 16 (3.7%) (Table 4).

Table 5: Grade of acne vulgaris.

Acne grade	Male (n=176) (%)	Female (n=253) (%)	No. (n=429) (%)
1	27 (15.3)	81(32)	108 (25.2)
2	122 (69.4)	161(63.6)	283 (66)
3	15 (8.5)	7 (2.8)	22 (5.1)
4	12 (6.8)	4 (1.6)	16 (3.7)

X^2=26.31; p<0.0001.

Grade 2 acne was observed in 283 (66%) patients, followed by grade 1 in 108 (25.2%) patients, grade 3 in 22 (5.1%) patients and grade 4 in 16 (3.7%) patients (Table 5). Male 122 (69.4%) patients and female 161 (63.6%) patients had grade 2 acne vulgaris (Table 5). In our study, patients having acne more than 60 months duration had grade 3 or grade 4 acne.

Table 6: Markers of androgenicity in the female (n=253).

Marker	Present (%)	Absent (%)
Hirsutism	67 (26.5)	186 (73.5)
Acanthosis nigricans	13 (5.1)	240 (94.9)
Seborrhea	95 (37.5)	158(62.5)
Increased muscle mass	0	0
Deepening of voice	0	0

In the study, seborrhea was observed in 95 (37.5%) female patients, followed by hirsutism in 67 (26.5%) and acanthosis nigricans in 13 (5.1%). None of the patient had increased muscle mass or deepening of voice. In female subjects, markers of androgenicity – such as hirsutism, acanthosis nigricans and seborrhea were more frequently seen in grade 2 acne and the association between them was statistically significant (p=0.045, p<0.0001, p value<0.0001 respectively) (Table 6).

Table 7: Associated cutaneous and systemic conditions.

	No (n=429)	%
Seborrhoea	261	60.8
Alopecia	81	18.9
Folliculitis	32	7.5
Acanthosis nigricans	21	4.9
PCOD	10	2.3

Seborrhoea was the most common dermatological association as seen in 261 (60.8%) followed by folliculitis in 32 (7.5%), acanthosis nigricans in 21 (4.9%), melasma in 9 (2.1%) and alopecia in 81 (18.9%). Polycystic ovarian disease (PCOD) was seen in 10 (2.3%) patients. According to BMI, 8 out of 10 PCOD patients were overweight, and 2 were obese. USG findings in all 10 patients were suggestive of PCOD. Seven patients of PCOD had diabetes mellitus and none of them gave a positive family history of PCOD. Clinical findings were irregular menses and hirsutism in 10 patients, Seborrhea in 6 patients and acanthosis nigricans in 8 patients (Table 7).

Table 8: Types of acne scars.

Types of acne scars	No (n=429) (%)
Atropic scars	
Icepick	344 (80.2)
Rolling	289 (67.4)
Boxscar	248 (57.8)
Hypertrophic	5 (1.2)
Keloid	1 (0.23)

Atrophic scars were commonest: icepick scars in 344 (80.2%), rolling scars in 289 (67.4%) and boxcar scar in 248 (57.8%) patients. Hypertrophic scar were present in 5 (1.2%) and keloids in 1 (0.23%) patient (Table 8).

DISCUSSION

The present study was done to study the clinical profile of patients of acne vulgaris in the Dermatology OPD of a medical college hospital and a possible correlation between acne vulgaris and markers of androgenicity in females. Acne vulgaris constituted 2.8% of all new patients attending Dermatology OPD. Other hospital based studies done in Asian population have reported acne vulgaris patients to be 1.06% to 19.6%.[7,8] The mean age of a patient of acne vulgaris was 20.66 (±4.05) years confirming acne vulgaris to be a primarily, a problem of the adolescent.

In the present study, female patients (59%) outnumbered male (41%) in the ratio of 1.44:1 with a mean age 21.68 (±4.29) years, a marriageable age group. The majority (90.9%) female patients were unmarried. These observations confirm the report of Al-Ameer et al and Tallab.[8,9] However Adityan et al have reported a larger

number of male patients in their study.[7] Similar finding were observed by Kane et al indicating the greater concern of facial appearance in female patients, of younger and marriageable age group.[10]

In the present study the mean age of onset in was 15.41 (±1.92) years, confirming observations of Adityan et al.[7] The age of onset in female was about 1.5 years earlier than in males and the difference was statistically significant ($p<0.0001$). Association between age of onset and age of puberty in our study was significant ($p<0.0001$). The observations confirm reports that acne develop earlier in females as compared to males due to an earlier onset of puberty.[1,11,12]

In the present study, the average mean duration of acne vulgaris was 39.81 months and severe acne were associated with a longer duration. Adityan et al had reported mean duration of acne as 45.55 months and patients with longer duration of the disease had more severe acne vulgaris.[7]

History of itching was noted in 186 (43.4%) patients and post inflammatory hyperpigmentation (PIH) in 286 (66.7%) of patients. Reich et al in their study reported itching in 50% and Lim et al in 70% of their patients.[13,14] Post-inflammatory hyperpigmentation is a common sequel in acne patients.[15] History of picking was noted in 326 (76%) patients and it was more common in female 204 (80.6%) as compared to male 122 (69.3%) patients. On the contrary, Pandey observed picking of acne to be more common in males as compared to females.[16]

In our study, face was involved in all the patients of acne vulgaris (100%), back in 25.6%, arms in 19.3%, chest in 17.5% and neck 7.5%, whereas only face involvement was seen in 67.1%. These observations are in accordance with data from earlier literature.[1,7] The primary and the pathognomonic lesion of acne vulgaris is a comedone, which may be open or closed.[1,4,17] In the present study, closed comedones were observed in 97% of our patients whereas open comedones were seen in 52% of our patients. Similar results were noted by Adityan et al.[7]

Acne vulgaris is a disease with polymorphic eruptions.[1] In our study, the severity of acne vulgaris was graded using a simple and quick system of classification of four-grade system.[6] Grade 2 acne was seen in 283 (66%) patients followed by grade 1 in 108 (25.2%), grade 3 in 22 (5.1%) and grade 4 in 16 (3.7%) patients. Patients with grade 2 acne vulgaris outnumbered patients with more severe inflammatory forms of the disease. Similar findings were noticed by Kane et al.[10] However, Adityan et al observed grade 1 acne vulgaris to be 60.2% of patients.[7] In the present study, grade 4 acne vulgaris was observed in 6.8% male patient as compared to 1.6% female patients ($p<0.0001$). This observation is in accordance to studies of Tallab and Adityan et al.[7,9]

Although acne is not an inherited condition, there is an inherited predisposition.[18,19] We observed family history of acne in 52.5% of our patients; 62.5% patients of grade 4 acne vulgaris had a positive family history of acne. Cunliffe and Gollnick reported family history in 40% and Kubota et al in 56.8% of their patients of acne vulgaris.[20,21]

In our study, acne scarring was seen in 80.2% patients. Incidence of post acne scarring is observed to vary from 5.9% to 40.2%.[4,7,10,22] We observed that patients with longer duration of disease were more likely to have post-acne scarring and the association between them was statistically significant ($p<0.0001$) and this finding is in accordance with earlier studies.[7,23]

Whereas, ice-pick scar was the most common type of post-acne scar and it was universally present in all patients of post acne scaring. Similar findings were noticed by Layton et al.[23] However, we observed a higher percentage of post acne scarring as this may be a phenomenon in the North Indian race or may be due to longer duration of disease which was present in majority of patients and habit of picking might have played its important role.

In our study, premenstrual flare was noticed in 62.8% of female patients. Incidence of premenstrual flare is reported to vary from 39.1% to 57.7% by Adityan et al, Stoll et al, Ikaraoha et al, and Kubota et al.[7,24-26] In the present study, irregular menses was noted in 28.9% of female patients. Similarly, irregular menses noted in earlier studies varied from 10.2% to 48%.[7,27]

Markers of androgenicity in female patients such as hirsutism was observed in 26.5% of patients. Similarly, in earlier studies it varied from 0% to 21%.[7,27] Seborrhea was observed in 37.5% of female patients followed by acanthosis nigricans in 5.1% female patients. Seborrhea plays a central role in the pathogenesis of the disease.[7] In the present study, seborrhoea was observed in 60.8% of patient and it was associated with severe grades of acne ($p<0.0001$). Similar results were seen in Pandey study.[16]

Other associated conditions, seen in our study, were alopecia in 18.9% of patients, folliculitis in 7.5% of patients, acanthosis nigricans in 4.9% and melasma in 2.1% of patients. Most of the patients, having alopecia had traction alopecia and androgenic alopecia. Folliculitis is a known association of acne vulgaris. More over in our study, many of the patients were using hair oil which may be the underlying factor. Acanthosis nigricans was seen commonly in obese patients and polycystic ovarian disease patients. The only associated systemic disease was polycystic ovarian disease. Similarly, Adityan et al found polycystic ovarian disease as associated condition in 17 patients in their study.[7]

In our study, 10 patients were of PCOD, confirmed by USG of lower abdomen. However, 60% patients had

elevated luteinizing hormone (LH) level, 30% had normal and 10% had below normal level; 30% patients had elevated follicle stimulating hormone, 70% had normal; 90% patients had altered LH/FSH (that is above 2) and 10% patients had below 2; 40% patients had elevated testosterone level and 60% had normal level. Hormonal investigations were done as close to menses as possible. There may be some patients haven't had the exact idea of timing of their menses. Hence there may be slight variation in percentage as reported in earlier available literature.[28]

CONCLUSION

Female patients of acne vulgaris outnumbered male in the ratio of 1.44:1 and belonged to the age group 16 to 25 years. Mean age of onset of acne was 15.41 (±1.92) years with onset earlier in females. The average total duration of acne vulgaris was 39.81 months and those with longer duration of the disease had more severe form. Post-inflammatory hyperpigmentation was common and habitual picking is more frequent in females.

Face is the most common site and closed comedone the most common acne lesion (97%) followed by open comedone (52%). Patients with grade 2 acne vulgaris form the majority of patients. Grade 4 acne vulgaris is more common in males (6.8%) as compared to females (1.6%). Premenstrual flare of acne was seen in majority (62.8%) of female patients.

Seborrhoea (60.8% of patients) was the most common association followed by alopecia (18.9%), folliculitis (7.5% of patients) and acanthosis nigricans (4.9% of patients). Polycystic ovarian disease (2.3%) was the most common associated systemic disease. Common clinical markers of androgenicity in female patients; were hirsutism in (26.5%), acanthosis nigricans in (5.1%), seborrhea (37.5%). In female patients associated with PCOD, FSH, LH and testosterone level levels were normal but FSH-LH ratio was altered.

Diagonal Earlobe Crease: Prevalence and Association with Medical Ailments

Yugantara Ramesh Kadam, MD[1]; Yogesh M Shah, MD (DVL)[2]; Parth Kore, MBBS[1]

Departments of [1]Community Medicine, Bharati Vidyapeeth Deemed University Medical College and Hospital, Sangli, Maharashtra, [2]Department of DVL, Era's Lucknow Medical College and Hospital, Lucknow, Uttar Pradesh, India

Abstract

Context: It has been hypothesized that diagonal earlobe crease (DELC), "Frank's sign" is indicative of coronary artery disease (CAD) and/or diabetes mellitus (DM). Several studies have confirmed an association between DELC and cardiac morbidity, mortality, and hypertension (HTN). However, some studies have not found any significant association. **Aims:** This study aims to find out the prevalence of DELC and its association with CAD, DM, and HTN. **Settings and Design:** Sangli-Miraj-Kupwad Corporation area. This was a cross-sectional analytical study. **Subjects and Methods:** Study participants: Adults from 18 to 60 years age. Inclusion criteria: willing to participate in the study Exclusion criteria: Wearing heavy ear rings and excessive normal generalized wrinkling of the skin. Sample size: Sample size 6310, determined after a pilot study revealing DELC in 1.5%. Sampling technique: Two-stage cluster sampling. Duration of study: 6 months. Study tools: Predesigned, pilot tested pro forma. **Statistical Analysis:** Statistical analysis was done by using SPSS 22 software. Prevalence and percentages were calculated, and Chi-square test was applied. **Results:** Out of 6638 participants, 179 had DELC. The prevalence of bilateral DELC was 2.7%. The prevalence was significantly high among males (4.13%) and in the 51–60 years age group (5.29%). The prevalence of Grade 3 DELC was high and 91% of young adults had Grade 3 DELC. There were 408 (6.15%) participants who gave a history of CAD, 827 (12.46%) of DM, and 670 (10.09%) HTN. Significantly high association observed between DELC and CAD, DM, and HTN. CAD, DM, and HTN were significantly associated with Grade 3. **Conclusions:** The prevalence of bilateral DELC was 2.7% and is significantly associated with CAD, DM, and HTN.

Introduction

Bilateral diagonal earlobe crease (DELC), also called "Frank's sign," was first reported to be associated with risk factors for coronary artery disease (CAD) by Frank.[1]

Several reports thereafter have confirmed an association between earlobe crease and CAD.[2-8] It has been reported that DELC is associated with increased cardiac morbidity and mortality.[9] An association between DELC and systolic hypertension (HTN) is also reported.[10] However, some studies have not found any significant association between DELC and CAD.[10] Agouridis *et al*. mention that even though it is evident that there is an association between DELC and CAD, there are some limitations to say so.[11]

The pathophysiological link between DELC and CAD can be explained as both the earlobe and heart are supplied by "end arteries" without the possibility for collateral circulation.[9] The microvascular disease results into loss of elastin and elastic fibers in the earlobe causing DELC. The presence of DELC may reflect the presence of a similar microvascular disease in the coronary circulation in the individual.[9] Hence, DELC may be used as a sign for prediction of CAD.

The prevalence of DELC in general population is not available as all available studies are hospital based. Indians as a community are more prone to CAD, Diabetes Mellitus (DM), and HTN and at a much younger age. Hence, this study was planned to find out the prevalence of DELC and its association in known patients with CAD, DM, and HTN.

Subjects and Methods

A cross-sectional study was conducted in Sangli-Miraj-Kupwad Corporation (SM and KC) area, Maharashtra, India. Study participants were adults of both sexes and with age ranging from 18 to 60 years. Study participants wearing heavy ear rings or with excessive generalized wrinkling of the skin were

excluded. Sample size was calculated by using prevalence of DELC (1.5%) as obtained from a pilot study. Calculated sample size was 6310 (α = 5%, zα = 1.96, P = 1.5%, d = error 20%). Two-stage cluster sampling technique was used for selection of study participants. There are total 71 wards in SM and KC area. One ward from each area (Sangli, Miraj and Kupwad) was selected. House-to-house visit was paid to identify study participants. All participants willing to participate in the study were included till the desired sample size was achieved. All available and eligible participants from a house were included.

A well-designed questionnaire as per the need of study was developed to collect and record the data of the participant. The questionnaire was pretested and used for pilot study also. Four interns were identified and were trained by investigator with the help of power point presentation for identification, grading of DELC, and for data collection by using the questionnaire. Trained interns were provided with the photograph of DELC to help them in explaining about the study to participants.

The study participants were asked about history of three medical ailments – CAD, DM, and HTN, and the answer was recorded.

Definition and grading of the diagonal earlobe crease

The DELC is an earlobe crease extending diagonally from the tragus across the lobule to the rear edge of the auricle.[1] In the study, the participant is diagnosed to have DELC only when the said crease is bilateral. The severity of DELC is graded as follows:[12] Grade 1: A small amount of wrinkling on the earlobe [Figure 1], Grade 2a: Creased more than halfway across the earlobe [Figure 2], Grade 2b: A superficial crease across the earlobe [Figure 3], and Grade 3: A deep crease across the whole of the earlobe [Figure 4].

Statistical analysis

Statistical analysis was done by using SPSS 22 software (IBM Corp, Armonk, New York, USA). Prevalence and percentages were calculated. Chi-square test was applied to find out the association between DELC and diseases, namely, CAD, DM, and HTN.

Results

Total participants interviewed during survey were 6638, out of which 3035 were females and 3602 were males. Age of the participants ranged from 18 to 70 years, mean age being 43.80 years standard deviation (SD) ±13.51.

Out of 6638 individuals, 179 had bilateral DELC. Grade-wise distribution of DELC was as follows: Grade 1: 51 (28.49%), Grade 2a: 38 (21.23%), Grade 2b: 26 (14.53%), and Grade 3: 64 (35.75%).

The prevalence of bilateral DELC was 2.7%. The prevalence of Bilateral DELC in males was 4.13% (149) and in females, it was 0.99% (30). The prevalence of DELC was significantly more common in males (χ =37.32, P = 0.00) [Table 1].

Mean age of participants without bilateral DELC was 43.52 years with SD ± 13.42. In contrast, mean age of persons with bilateral DELC was 53.43 years with SD ± 13.47 (z = 9.71, P = 0.00). The prevalence of bilateral DELC was significantly high in the 51–60 years age group (5.29%, χ^2 = 94.73, P = 0.00). Interestingly, 91% of

Figure 1: Grade 1 – A small amount of wrinkling on the earlobe

Figure 2: Grade 2a – Creased more than halfway across the earlobe

Figure 3: Grade 2b – A superficial crease across the earlobe

young adults of age between 18 and 35 years having DELC had DELC of Grade3 [Table 2].

History of CAD was present in 408 (6.15%) participants, history of DM in 827 (12.46%), and history of HTN in 670 (10.09%).

Out of 179 persons with DELC, 36 (20.1%) had history of CAD (χ^2 = 62.19, P = 0.00), 34 (19%) had DM (χ^2 = 7.20, P = 0.00), and 42 (23.5%) had HTN (χ^2 = 36.23, P = 0.00) [Table 3].

Maximum study participants with CAD had DELC of Grade 3 and 2a. DM was present mainly in participants with Grade 2b and Grade 3 DELC. Maximum study participants with HTN had Grade 3 DELC. Significant association was observed between grades of bilateral DELC and DM (χ^2 = 38.43, P = 0.00) and HTN (χ^2 = 16.18, P = 0.001).

Discussion

DELC has been suggested as a marker of generalized atherosclerosis. It has been already stated that both earlobes and heart are supplied by "end arteries" where possibility for development of collateral circulation is low. Histopathology studies of biopsies from earlobe in cases of DELC have reported loss of elastin fibers indicating a generalized microvascular disease and hinting at possibility of similar changes in coronary arteries in the affected individuals.[2]

Figure 4: Grade 3 – A deep crease across the whole of the earlobe

Majority of clinical, angiographic, and postmortem study reports support the proposition that DELC may be associated with CAD and can be used as a valuable indicator which can be observed/identified easily clinically.[2,3,4,13-17] Ramos *et al*. have studied and concluded that ear creases are independently associated with peripheral arterial disease and may be an external marker for risk identification.[18] In addition, Kang and Kang found association between earlobe crease and the metabolic syndrome.[19] Elliot and Karrison conducted a prospective cohort study and found a positive association between DELC and all cause morbidity and mortality including cardiac cause.[9] In another study, Elliot and Powell found earlobe creases to be associated in a graded fashion, with a higher rate of cardiac events.[20]

In "a review of the medical literature and dental implications," authors conclude that even though more research is needed in this area, it is advisable for a dentist to use DELC as a vital sign along with the medical history and other signs for risk assessment and medical evaluation.[21] A positive association between DELC and CAD was observed in the present study.

Most studies of "prevalence" of DELC are actually hospital-based studies while ours is a community-based study. The prevalence of DELC was found to be significantly higher in males. This finding of male preponderance is also noted by other studies, even though the studies were hospital based.[2,4] It was observed that prevalence of DELC was mainly present in the older age and similar findings are noted by other investigators.[2]

DELC was also observed to be significantly associated with DM and HTN in our study. DM and HTN are independent risk factors for CAD, and patients with DM and HTN are vulnerable to atherosclerosis. This fact may explain a significant association between DELC, DM, and HTN.

Telomeres shorten during the replication of somatic cells, leading to attrition in the length of telomere indicating progressing biological age. Telomere length in leukocytes reflects the cumulative burden of oxidative stress and inflammation in the circulation during an individual's lifetime and has been reported to be a useful marker of biological aging of the cardiovascular system.[22] Atherosclerosis, essential HTN, and noninsulin-dependent DM are age-related disorders, and telomere length is one of a number of biologic

Table 1: Age-wise distribution of persons with diagonal earlobe crease

indicators that may serve to assess the progression of biologic aging in humans.

A study conducted on male Japanese patients with metabolic syndrome found association between DELC with a shorter telomere. Hence, the researchers concluded that DELC might be a useful indirect marker of high-risk patients.[22]

Pasternac and Sami concluded in their study that "the ear-crease sign" could identify patients who are aging earlier than usual and are thus at risk of CAD prematurely and whose prognosis might be improved by early preventive measures.[23]

In the present study, only self-reported cases of CAD, DM, and HTN were considered. Therefore, many of the undiagnosed cases may have been missed. In spite of this limitation, on the basis of statistical results and results reported by several other studies, we can say that there is an association between DELC with CAD, DM, and HTN. Considering the pathophysiology of DELC, DELC may be said to be the external presentation of atherosclerosis. This atherosclerosis could be because of aging or accentuated by DM and HTN leading to CAD.

At present, the association between the time of onset of DELC and that of atherosclerosis is not known. Thus, considering all these aspects, we can conclude that whenever there is DELC, we should plan to evaluate the individual for CAD, DM, or HTN.

Conclusions

The prevalence of bilateral DELC was 2.7% and was significantly associated with CAD, DM, and HTN. Therefore, bilateral DELC, a visual cutaneous clinical marker, can be used as a screening tool for early diagnosis and prevention of CAD and other related diseases.

ABSTRACT

Background: Management of keloid is difficult as well as challenging. Intralesional triamcinolone acetonide (TAC) injections have remained a gold standard in non-surgical management of keloid. TAC is generally used in the concentration of 40mg/ml, which causes adverse effects such as local dermal atrophy and hypopigmentation. Aim was to study efficacy and adverse effects of TAC in treatment of keloid, in a lesser concentration of 20mg/ml.
Methods: An open label study was conducted from November 2015 to May 2017 on 25 subjects of either gender, in the age group 11-55 years, at a medical college hospital. Intralesional injection TAC 20 was administered in the keloid at an interval of 3 weeks, for a total of 6 sessions, over a period of 18 weeks. Vancouver scar scale (VSS) was used to assess the improvement and SPSS 21 for statistical analysis.
Results: Mean age of keloid subjects was 30.72 years and median duration of keloid was 8 months. The mean VSS score before treatment was 8.36 which reduced to 3.20 after treatment. Mean percentage change in VSS score was 62.79%, which was very highly significant ($p < 0.001$). Physician's assessment was 'Very Good' in 52.0% and 'Excellent' in 5 (20%). Adverse effect of atrophy was seen in 3 (12%), hypopigmentation in 11 (44%) and telangiectasia in 4 (16%).
Conclusions: Intralesional injection triamcinolone acetonide 20mg/ml gives very good to excellent improvement in the majority of patients of keloid. Local adverse effects seen were hypopigmentation, atrophy and telengiectasia.

Keywords: Adverse effects, Efficacy, Keloid, Triamcinolone (20mg/ml), Vancouver scar scale

INTRODUCTION

Keloids are characterized by firm, mildly tender, bosselated nodules or plaques occurring more frequently on shoulders, chest, neck, upper arms and face.[1] They are benign overgrowth of fibrous tissue that usually develops after healing of a skin injury and extends beyond the original defect.[2] The uncontrolled growth of keloid continues progressively, and the patients experience itch and pain. The fibrous keloid progresses to gain a larger size, leads to cosmetic disfigurement, functional impairment, and affects the quality of life adversely.[3]

It is supposed that corticosteroids owing to their anti-inflammatory properties are helpful in suppressing hypertrophic scars and the keloid.[4] The corticosteroids diminish collagen and glycosaminoglycan synthesis, inhibit fibroblast growth and enhance collagen and fibroblast degeneration.[5,6]

Triamcinolone acetonide (TAC) is the most commonly used intralesional corticosteroid for the treatment of keloids and is considered to be the first line therapy for the treatment of keloids.[7] TAC is used in different concentrations ranging from 10 to 40mg/ml. Different studies recommend different intervals between successive injections and the number of injections may vary from four to eight.[8]

Intralesional injection TAC 40mg/ml is more commonly used, as the concentration of 40mg/ml is very effective in controlling keloid. However Local side effects such as dermal atrophy, telengiectasia, hypopigmentation and pain at the site of injection due to TAC 40mg/ml are common. Pain can be avoided by use of topical anesthesia and/or regional injections of local anesthetic around the scars.[9] Hypopigmentation is not a problem in non-pigmented western skin but is significant in pigmented skin.

Aim was to study the efficacy and the adverse effect of intralesional injection triamcinolone acetonide in treatment of keloid, in concentration of 20mg/ml.

METHODS

The study was carried out on 25 patients in Dermatology OPD of a medical college hospital in North India from November 2015 to May 2017 (one year and six months). Patients of keloid of either gender, in the age group 11 to 55 years, were included in the study. Patients with local infection, immune-compromise, pregnancy or lactation and those who had received treatment for keloid during previous 6 months were excluded. Sample size was calculated on the basis of decrease in volume of the keloid.[10]

Injection Triamcinolone acetonide 20mg/ml (TAC 20) was injected intralesionally at an interval of 3 weeks, for a total of 6 sittings over a period of 18 weeks. Injection Triamcinolone acetonide 40mg/ml was diluted using lignocaine with adrenaline, in equal proportions, to get a final concentration of 20mg/ml. The lesion was infiltrated with the drug suspension, using a disposable insulin syringe and 26-gauge needle, till complete and uniform blanching of the lesion, was achieved. The subject was not administered any sedation or analgesia prior to the injection.

The details of the subject including the Fitzpatrick skin type, duration, site, number and parameters such as height, pliability, vascularity and pigmentation of the keloid assessed on Vancouver Scar Scale (VSS), were recorded in a predesigned "Case record form." VSS was assessed before treatment and three weeks after completion of the treatment.

VSS is a validated and widely used tool to document a change in appearance of the scar, in clinical practice and research.[11-13] Parameters of the keloid such as vascularity, pliability, pigmentation and height are assessed, in order to determine the score. The score allotted for pliability is from 0 to 5, score for height and vascularity from 0 to 3 and for pigmentation from 0 to 2, to give a maximum possible score of 13. The decreasing mean value of the total score indicates clinical improvement, in the scar.

Scar height was measured with calipers, and scar pliability assessed by palpation; scar vascularity rated by visual inspection, and the rate of refill, after blanching it. Blanching was achieved by a transparent plastic sheet with VSS score sheet, pasted on it. Scar pigmentation was assessed after blanching and comparing the scar color with the surrounding skin.[13] The percentage reduction in VSS was graded according to the Quartile score with ≤25% reduction in VSS graded as Poor, 26-50% reduction as Good, 51-75% reduction Very good and >75% reduction as Excellent response.

Data was analyzed using Statistical Package for Social Sciences (SPSS) version 21.0. Wilcoxon signed rank was used to assess the outcome and 'p' value less than 0.05 was considered to be a statistically significant change.

RESULTS

A total of 25 subjects of keloid of either gender, were treated with intralesional injection of triamcinolone acetonide 20mg/ml (TAC-20). All the 25 subjects completed the study. Male were 52%, female 48% and the mean age was 31.76±13.08 years. Family history of keloids was present in 4 (16.0%). The majority (60.0%) of the subjects had Fitzpatrick Skin type IV. Duration of keloid ranged from 1 to 36 months with a median duration of 7 months.

Table 1: Demographic data.

Keloid patients		Value
Gender	Male	13 (52%)
	Female	12 (48%)
Age (year)	11 to 55	Mean 31.76±13.08
Family history	Positive	4 (16.0%)
	Negative	21 (84%)
Skin Photo-type	Type IV	15 (60.0%)
	Type V	10 (40.0%)
Duration (months)	1 to 36	Median 7

The majority (92%) had one or two keloids and 2 (8%) of the subjects had more than three keloids.

Table 2: Number of keloids.

Patients	Number of Keloids
18 (72%)	1
5 (20%)	2
0 (0%)	3
1 (4%)	4
1 (4%)	5

The majority (90%) of keloids were either on the chest or shoulders.

Table 3: Location of keloids.

Location on the body	No. of keloids (30)
Chest	16 (52 %)
Shoulder and arm	11 (38 %)
Face and ear	3 (10 %)
Back	0 (%)
Thigh and leg	0 (%)

An assessment of Vancouver Scar Scale (VSS) score was carried out at the baseline i.e. before the treatment, and at 3 weeks after the last (sixth) injection, i.e. at 18 weeks from the first injection: Before starting the treatment, at the baseline, mean VSS score was 8.36±1.60 (Median 8.0), which reduced to 3.20±1.92 (Median 3.00) at final follow up, thus showing a mean change of -5.16±1.63 (62.79%). On evaluating the data, it was found to be statistically significant ($p<0.001$).

Table 4: VSS score following treatment with intralesional injection of triamcinolone acetonide.

VSS score (n=25)	Median	Mean	SD
At baseline	8.00	8.36	1.60
4.5 months (final follow up)	3.00	3.20	1.92

Mean±SD -5.16±1.63 % change -62.79%; z=4.401; $p<0.001$

Figure 1: Pretreatment photograph of keloid on back of shoulder.

Physician rated outcome was 'Very good' to 'Excellent' in 18 (72%) and 'Good' in 5 (20%) subjects. There were 2 (8%) cases in which outcome was evaluated as 'Poor'.

Table 5: Physician rated outcome.

Assessment	n = 25
Poor	2 (8%)
Good	5 (20%)
Very good	13 (52%)
Excellent	5 (20%)

Figure 2: Post-treatment photograph after TAC-20 (excellent response).

Figure 3: Pretreatment photograph of keloid.

Figure 4: Post-treatment photograph of keloid after TAC20 (very good response but with atrophy and telengiectasia).

Pain was the most common adverse effect as reported by 21 (84%) patients. Hypopigmentation was observed in 11 (44%), telengiectasia in 4 (16%), and dermal atrophy in 3 (12%) of the subjects (Table 6).

Table 6: Adverse effects.

Adverse Effects	n = 25
Pain	21(84%)
Hypopigmentation	11 (44%)
Telangiectasia	4 (16%)
Dermal atrophy	3 (12%)

DISCUSSION

Pathogenesis of the keloid is still not well understood.[14] A variety of treatment modalities such as silicone gel sheeting, intralesional injections, cryotherapy, surgical manipulation, laser and radiotherapy are used, but no particular treatment is suitable or effective in all cases and keloid it tends to recur, irrespective of the treatment used.[8] Drugs like bleomycin, interferon, 5-fluorouracil when used intralesionally, have a better efficacy, but are costly and cause severe drug reactions. Surgery and laser therapy have limitations and radiotherapy causes malignancy.[15]

Corticosteroids seem to be effective as they diminish collagen and glycosaminoglycan synthesis, inhibit fibroblast growth, enhance collagen and fibroblast degeneration and have powerful anti-inflammatory effect.[4-6] The anti-inflammatory effect of TAC in addition to inhibition of collagen and glycosaminoglycan synthesis, and degeneration of fibroblast/collagen might be giving it an edge, however the drug causes local adverse effects such as dermal atrophy, telengiectasia and hypopigmentation in large number of patients.

Inability to measure amount of drug used with respect to area as well as thickness of keloid, has been a major limitation in this study as in most other studies. Consequently, complete blanching of the keloid, was considered to be the end point, for the dose of the drug injected intralesionally.

TAC is cost effective and practical and has become first-line treatment for keloid, in spite of many limitations. Studies have reported that lower dose of TAC, i.e. 20mg/ml reduces the side effects of TAC without jeopardizing the efficacy.[16-18]

In this study, majority of the subjects were in the age group <30 years; males being slightly more than females. Uzair et al and Ahuja et al also observed predominance of keloid in the younger age group.[19,20] The duration of keloids in majority of subjects was less than 12 months. The majority showed a very good to excellent response conforming observations from studies.[21,22] The Keloid were found to be most common on the chest (60%), followed by shoulder (20%), arm (18%) and face (10%) similar to observations.[23]

In the present study following intralesional TAC 20, a majority (62.79%) of patients of keloids showed significant mean reduction in VSS. The observations were in conformity with that of Uzair et al.[19] The improvement observed was comparable to TAC 40mg/ml used by Chatterjee A and Shanthi M et al.[15,20] The improvement in keloid with TAC 20 mg/ml was observed to be similar to TAC 40mg/ml used in other studies.[15,19,20,23,24]

Immediate pain at the site of injection was the commonest side effect with TAC 20 as reported by 84% of the subjects. However, the pain was mild, transitory and resolved within few hours, which is attributed to dilution with lignocaine and adrenaline which causes a sustained hypoesthesia and therapeutic effect at the site, locally. Hypopigmentation was observed in 44%, atrophy in 12% and telengiectasia in 16% of the subjects treated by TAC 20; this was comparable to other studies.[25-27] Manuskiatti et al and Jannati et al using TAC-20, reported hypopigmentation in 20%, atrophy in 10% and telengiectasia in 20% of patients.[23,28] Bilal et al using TAC 40mg/ml reported hypopigmentation (29%), atrophy (4%) and telengiectasia (25%).[29] An occurrence of atrophy in 18% of cases was from studies.[20]

In the present study with TAC 20, hypopigmentation was observed in 44 % of the subjects. The incidence of hypopigmentation in the study was much higher as compared to other studies probably because all subjects in this study, were of Fitzpatrick skin type IV and V. Most other studies do not mention the skin phototype of the subjects.

Limitations of the study includes therapeutic effect of injection TAC was studied over a period of only 18 weeks for a patient, which may be inadequate. Post treatment follow up of patient should be of a longer period to judge the recurrence.

CONCLUSION

TAC 20mg/ml gives very good to excellent response in a majority of patients and the improvement is comparable to the result with TAC 40mg/ml as reported by other workers. TAC 20 also causes adverse effects such as hypopigmentation, telengiectasia and atrophy. However adverse effects with TAC 20 are less compared to TAC 40. Immediate postoperative pain occurs but is mild and transitory.

ABSTRACT

Background: Keloid is a common presentation in clinical practice. Symptoms due to keloid are mild, but disfigurement and functional impairment can be severe. It is difficult to treat. Intralesional, injection triamcinolone acetonide, has limited efficacy, causes adverse effects such as local dermal atrophy, telengiectasia and hypopigmentation. Injection verapamil is reported to have similar efficacy, but lesser side effects, and is cheaper. Aim was to study efficacy and adverse effects of intralesional verapamil in treatment of keloid.
Methods: An open label study on 25 patients of keloid, either gender, age 11 to 55 years at a medical college hospital. Injection verapamil 2.5 mg/ml was administered intralesionally, at an interval of 3 weeks, for a total of 6 sittings, over a period of 18 weeks. Vancouver scar scale (VSS) was used to assess the improvement. The statistical analysis was done using SPSS version 21.0.
Results: Median duration of keloids was 8 months. The mean VSS score before treatment was 7.68 which reduced to 4.28 after treatment. Mean percentage change in VSS score was 46.21%, very highly significant ($p<0.001$). Physician's assessment was 'very good' in 32.0% and 'excellent' in 8.0%. The complaint of post-procedure pain was present in almost all.
Conclusions: Intralesional injection verapamil, gives very good to excellent improvement in 40% of patients of keloid. Post injection pain persists for more than 24 hours. Drug does not cause local dermal atrophy or hypopigmentation.

Keywords: Keloids, Intralesional, Verapamil, Efficacy, Vancouver scar scale

INTRODUCTION

Keloid is an area of benign overgrowth of fibrous tissue that usually develops after healing of a skin injury, and extends beyond the original defect.[1] Keloids clinically manifest as raised, hyper-pigmented, erythematous nodules or plaques, with an irregular border, making them visible and distinct from the surrounding skin.[2] Patients with darker skin have a higher prevalence for keloid than lighter skin.[3] It is the fifth most common skin disease in adult black patients, in the United Kingdom.[4]

Symptoms of itch and pain due to keloid are mild, but the disfigurement and functional impairment can be severe. It leads to aesthetic and physical complaints, causing psychogenic turmoil and severe depression in affected individuals.[5-7] Intralesional triamcinolone acetonide (TAC) is considered to be the first line of treatment, however it is effective only against younger keloids, response rate varies from 50% to 100%, and a recurrence rate of 9% to 50% is reported.[8] Local side effects due to TAC include dermal atrophy, telengiectasia and pain at the site of injection.

Verapamil, a calcium channel blocker, and an antiarrhythmic agent, has emerged as a useful treatment modality in treatment of keloids.[9] It is reported to decrease IL-6 and vascular endothelial growth factor in the central keloid fibroblasts, reducing cell proliferation, increasing apoptosis and expression of decorin, thus inhibiting fibroblast proliferation and migration and reducing keloid.[10] It is reported that VPL has lesser side effects as compared to TAC, is cheaper and could be a suitable alternative to TAC.[11] Aim was to study efficacy and adverse effects of intralesional verapamil in treatment of keloids, by assessing clinical improvement using Vancouver scar scale (VSS).

METHODS

The study was carried out on 25 patients in Dermatology OPD of a medical college and hospital, Uttar Pradesh, India, over a period of one year and six months, with due permission of Institutional Ethics Committee. Keloid patients of either gender, in the age group 11 to 55 years, were included in the study. Patients with immuno-compromised status, local infection, pregnant or lactating mothers and those who had received any specific treatment for keloid within previous 6 months were excluded. Sample size was calculated on the basis of decrease in volume of keloid.[12]

Injection verapamil (VPL) 2.5 mg/ml was administered intralesionally at an interval of 3 weeks, for a total of 6 sittings, over a period of 18 weeks (4.5 months). Injection Verapamil needs no dilution as it is available in the required concentration of 2.5 mg/ml (vial: 5 mg/2 ml). The lesion was infiltrated with the drug solution, until complete and uniform blanching of the lesion was achieved, using a disposable insulin syringe, and 26 gauge needle. No sedation/analgesia was used prior to the injection.

The details of the subject were recorded in a predesigned "case record form" which included the Fitzpatrick skin type, duration, site, number and various other parameters of the keloid. Height, pliability, vascularity, pigmentation and size of the keloid were assessed on VSS. VSS was assessed before treatment with Injection VPL, and after completion of the treatment at 18 weeks.

VSS is a validated tool to document a change in appearance of the scar and is widely used in clinical practice and research.[13-15] It was first described by Sullivan in 1990.[16] Vascularity, pliability, pigmentation, and height of the scar are the parameters assessed to determine the score, in VSS. The score for pliability ranges from 0 to 5, height and vascularity from 0 to 3 and pigmentation from 0 to 2, to give a maximum score of 13. The decreasing mean value of the score indicates clinical improvement in the scar.

Scar height was measured with calipers, scar pliability subjectively assessed by palpation, scar vascularity was rated on visual inspection, and the rate of refill after blanching the keloid. Blanching was achieved by a transparent plastic sheet with VSS score sheet pasted on it, as suggested by Baryza and Baryza.[15] Scar pigmentation was assessed after blanching, and comparing the scar color with the surrounding skin.

The percentage reduction in VSS was graded according to the quartile score with ≤25% reduction in VSS, graded as poor, 26-50% reduction as good, 51-75% reduction very good and >75% as excellent response.

Statistical analysis

Data was analyzed using Statistical Package for Social Sciences (SPSS), version 21.0. Wilcoxon signed rank was used to assess the outcome. A 'p' value less than 0.05, indicated a statistically significant change.

RESULTS

A total of 25 patients of keloid, were treated with intralesional injection verapamil 2.5 mg/ml. All 25 patients completed the study. Male patients were 14 (56%) and female 11 (44%). Age of the patients varied from 12 years to 49 years, mean age was 30.72 (±11.23) years (Table 1). Family history of Keloid was present in 3 (12.0%) patients. The majority (64.0%) had Fitzpatrick skin type IV. Duration of Keloids ranged from 1 to 36 months with a median duration of 8 months (Table 1). The majority (92%) had one or two keloids; none of the patient had more than three keloids (Table 2). The majority (92%) of keloids were either on the chest or shoulders (Table 3).

Table 1: Demographic data.

Demographic characteistics		
Gender	Male 14 (56%), Female 11 (44%)	
	Ratio M:F- 1.27:1	
Age in years	12-49	Mean 30.72±11.23 yrs
Family history	+ve 3 (12.0%)	-ve 22 (88%)
Fitzpatrick skin type	Type IV (64.0%)	Type V skin (36.0%)
Duration	1 to 36 months	Median- 8 months

Table 2: Number of keloids.

Patients	Number of Keloids
15 (60%)	One
8 (32%)	Two
2 (8%)	Three

An assessment of VSS score was done at baseline and at 3 weeks, after the last injection, i.e. at 18 weeks from the first injection. At baseline, mean VSS score was 7.68±1.89 (median 8), which reduced to 4.28±2.21

(median 5) at final follow up, showing a mean change of 3.40±1.44 (46.21%). On evaluating the data statistically, it was found to be significant (p<0.001) (Table 4). Physician rated outcome was 'very good' to 'excellent' in 10 (40%) and 'good' in 11 (44%) cases. There were 4 (16%) cases in which outcome was evaluated as poor (Table 5).

Table 3: Location of keloids.

Location on the body	Number of keloids (%)
Chest	14 (56)
Shoulder and upper arm	9 (36)
Face and ear	4 (16)
Back	3 (12)
Thigh and leg	2 (8)

Table 4: Vancouver scar scale (VSS) score.

VSS score (n=25)	Median	Mean	SD
At baseline	8.00	7.68	1.89
At 4.5 months (final follow up)	5.00	4.28	2.21
Mean change±SD (% change)	3.40±1.44 (46.21%)		
Significance of change (Wilcoxon signed rank test)	z=4.401; p<0.001		

Table 5: Physician rated outcome.

Assessment	N=25 (%)
Poor	4 (16)
Good	11 (44)
Very good	8 (32)
Excellent	2 (8)

Table 6: Side effects.

Adverse effects	N=25 (%)
Pain	24 (96)
Hypopigmentation	0 (0)
Telangiectasia	0 (0)
Dermal atrophy	0 (0)

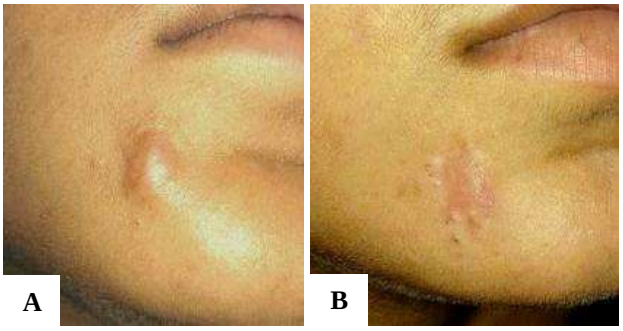

Figure 1: A= Before treatment; B= After 18 weeks of treatment (excellent improvement).

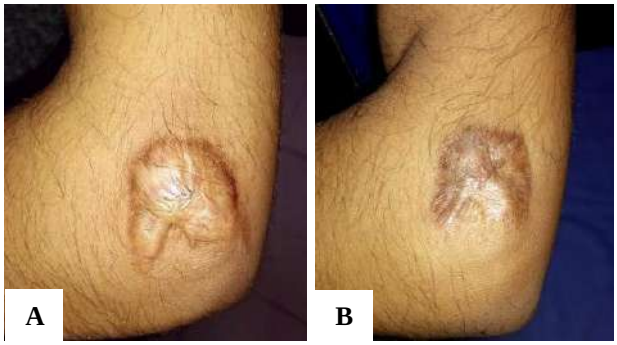

Figure 2: A= Before treatment; B= After 18 weeks of treatment (poor response).

Pain was the most common side effect as reported by 24 (96%) patients. None of the patients showed hypopigmentation, telengiectasia or atrophy (Table 6).

DISCUSSION

Keloids cause cosmetic disfigurement, functional impairment and a significant morbidity.[6,7] A variety of treatment such as pressure therapy, silicone gel sheeting, intralesional bleomycin or interferon or corticosteroid injections, cryotherapy, surgical manipulation, laser and radiotherapy are being used. No particular treatment is suitable or effective in all the cases of keloid.[17] Intralesional corticosteroids seem to be more effective, however they cause local adverse effects such as hypopigmentation, dermal atrophy and menstrual irregularities.

Among the emerging therapies, verapamil (VPL) is reported to be effective, relatively safer and much cheaper than TAC.[9] Verapamil inhibits the synthesis and secretion of extracellular matrix molecules, including collagen, glycosaminoglycans, fibronectin and increases collagenase by inducing procollagenase expression.[18] This study was done to evaluate efficacy of VPL in treatment of the keloid, in skin phototype IV and V. The drug VPL was used in the concentration of 2.5 mg/ml intralesionally, and VSS was used for assessment of the improvement.[19-21]

The actual amount of dose of the drug being injected, with respect to area and thickness of the keloid, cannot be measured as thickness of the keloid varies from lesion to lesion, and also within the lesion. Consequently in this study, complete blanching of the keloid at the time of intralesional injection, was considered to be the end point of the dose.

Majority of patients in this study, were in the age group ≤30 years; males being slightly more than females. Kant et al, Uzair et al, and Ahuja et al also observed predominance of keloid in the younger age group.[11,20,22] The presentation of the patient in the younger is more probably due to a greater esthetic concern in the young. The duration of keloids, in the majority of subjects was

less than 12 months. Keloids were observed to be commonest on the chest (60%), followed by shoulder (20%), arm (18%) and face (10%), similar to the findings of Jannati et al.[23]

In the present study, a mean reduction of 46.21% in all the parameters of the VSS, was observed at the end of 18 weeks. Uzair et al observed 36.75% reduction in VSS score, which was less than the improvement in the present study, however he had used only 3 injections of verapamil, one each at monthly interval.[20] In the present study, a total of 6 injections of VPL were administered, one each at 3 weeks interval, over a period of 18 weeks. Shanthi et al observed reduction in mean height of keloid from 4.33 mm to 0.15 mm, indicating an almost complete flattening, and maintenance of the improvement at 52 weeks.[19] Results obtained by Shanthi et al are markedly higher than the present study, but she used a total of 8 injections of VPL over a period of 6 months.

Danielsen et al compared efficacy of intralesional verapamil and triamcinolone acetonide (TAC) after surgical excision, to prevent recurrence of the keloid. They observed a recurrence of 20% in the verapamil group but none in TAC group.[21]

The commonest adverse effect was persistent pain at the injection site. The pain persisted for 24 to 48 hours and some required analgesics for relief. Hypopigmentation, dermal atrophy, profuse sweating and menstrual irregularities, which are common adverse effects due to administration of corticosteroids, were absent following intralesional VPL.[23-25]

Limitations of the study

Therapeutic effect of injection verapamil was observed over a period of only 18 weeks (4.5 months); ideal period of observation could be about 1 to 2 years.

CONCLUSION

Intralesional verapamil gives very good to excellent improvement in a large number of patients. The drug is available as a thin solution, and is easy to inject, using a fine gauge needle. It does not cause adverse effects such as local dermal atrophy or hypopigmentation, and is relatively safe. Pain following verapamil is severe and analgesics may be required.

ABSTRACT:

INTRODUCTION: About 60 per cent of TB cases and deaths occur among males, but the disease burden is also high among women also. In 2015 nearly 500,000 women died from TB, and among them, 28 per cent had human immunodeficiency virus (HIV) co-infection. Tuberculosis (TB) is a bacterial disease caused by *Mycobacterium tuberculosis (M. tuberculosis*), which mostly manifests as pulmonary TB but it can affect other organs called as extra-pulmonary Tuberculosis (ETB). TB is expanding public health issue amongst the developing countries, due to HIV pandemic, poverty, movement of displaced people and emergence of multidrug-resistant strains and it is evidenced that, in most of the developing countries, HIV pandemics, diabetes, malnutrition, alcoholism, smoking cigarette, active TB contact, extreme poverty, and homelessness are common identified risk factors pertaining to tuberculosis. **MATERIAL AND METHODS**: Patients who presented with cough lasting for 2 weeks, evening rise of temperature, weight loss or more were clinically suspected of having TB. Laboratory and radiological investigations were carried out. Laboratory investigation for TB was by sputum smear for acid-fast bacilli (AFB) and who had at least one smear positive for AFB were categorized as smear-positive pulmonary TB (PTB). Chest X-ray was done to detect radiological changes of PTB. Extra-pulmonary tuberculosis included tuberculosis of organs other than the lungs, such as the abdomen, genitourinary tract, lymph nodes, skin, bones, joints, and meninges. A diagnosis of extra pulmonary tuberculosis (EPTB) was made based on clinical findings suggestive of TB, radiology, cytology, and tissue histology. **RESULTS**: A total of 100 TB patients were included in the study. Age range was 15 to 59 years with mean age 37 ±15.9 years. HIV coinfection was found in 15 patients age range was 24 to 49 years with mean age 35 ±12.9 years. More than a half (*n*=10; 54.3%) of participants had CD4 count ranged between 200-500/µl and 21.6% (*n*=63) of respondents had CD4 count <200/µl. In addition, the study also showed that 29.2% (*n*=85) and 3.7% (*n*=11) . Of the 15 HIV positive diagnosed cases 5 were relapse case (33.33%) of which 2 were female and 3 were male . 10 cases (66.67%) were new cases of which 3 were female and 7 were male.MDR TB (multidrug resistant TB) was seen in 10 cases of HIV co infected patients as compared to HIV negative it was 15 cases. **CONCLUSION**: Drug-resistant TB is becoming a significant challenge to the control of the infection in the world especially in HIV-positive patients. Treatment should be targeted at treating the immune suppression associated with HIV which promotes development of active TB. Previous history of TB, CD4 count less than 200/µl were the possible risk factors.

KEYWORDS: TB, HIV, CD4 and ETB.

Introduction

Tuberculosis (TB) is a bacterial disease caused by *Mycobacterium tuberculosis (M. tuberculosis*), which mostly manifests as pulmonary TB but it can affect other organs called as extra-pulmonary Tuberculosis (ETB)[i]. Tuberculosis is a major health problem globally which affects millions of people every year. It has been ranked as the second leading cause of death from an infectious disease worldwide. The World Health Organization (WHO) estimated that there are over 9 million new active cases of tuberculosis resulting in 1.5 million TB deaths per year[ii]. Some epidemiological studies evinced that, co-infection with HIV can elevate the risk of latent TB reactivation by 20-fold and is the most potent risk factor known for the advancement of *M. tuberculosis* infection to active disease[iii]. TB is expanding public health issue amongst the developing countries, due to HIV pandemic, poverty, movement of displaced people and emergence of multidrug-resistant strains and it is evidenced that, in most of the developing countries, HIV pandemics, diabetes, malnutrition, alcoholism, smoking cigarette, active TB contact, extreme poverty, and homelessness are common identified risk factors pertaining to tuberculosis[iv] . The depressed immune system associated with HIV increases the risk of reactivation of latent tuberculosis and rapid progression to active infection. Therefore, areas with high HIV prevalence also have high TB incidence rate[v]. Generally pulmonary tuberculosis is the commonest TB manifestation and those who are HIV positive are more likely to have extra pulmonary TB. Extra pulmonary TB is seen in 40–80% of TB–HIV infection but in only 10–20% of patients without coinfection [vi],[vii]. Therefore HIV-related TB impacts negatively on the efforts to control tuberculosis. This study was carried out to determine the prevalence of TB–HIV coinfection among those being treated for TB, to compare the pattern of TB in HIV-infected and non-HIV-infected individuals.

MATERIAL AND METHODS

The present study was carried out in the Dept. of Pulmonary Medicine at Ananta Institute of Medical Sciences and Research centre, Rajsamand.

Patients who presented with cough lasting for 2 weeks, evening rise of temperature, weight loss or more were clinically suspected of having TB. Laboratory and radiological investigations were carried out. Laboratory investigation for TB was by sputum smear for acid-fast bacilli (AFB) and who had at least one smear positive for AFB were categorized as smear-positive pulmonary TB (PTB). Chest X-ray was done to detect radiological changes of PTB. Extra-pulmonary tuberculosis included tuberculosis of organs other than the lungs, such as the abdomen, genitourinary tract, lymph nodes, skin, bones, joints, and meanings. A diagnosis of extra pulmonary tuberculosis (EPTB) was made based on clinical findings suggestive of TB, radiology, cytology, and tissue histology. Patients with EPTB were treated using the directly observed treatment short course (DOTS) regimen of at least 6 months of anti-TB drugs which consists of 2 months of rifampicin, isoniazid, pyrazinamide, and ethambutol followed by 4 months of rifampicin and isoniazid.

After proper counselling and permission all patients were tested for HIV by an initial rapid test screening and confirmed by ELISA. Demographic and clinical information were retrieved from patients' records using a standardized questionnaire.

Data analysis was performed using the SPSS software. The Chi-squared test was used to test for association between categorical tables. The level of significance was set at $p \leq 0.05$.All data was entered on the EXCVEL sheet of Windows 2013.

Written informed consent was obtained from all the patients.

OBSERVATIONS AND RESULTS

A total of 100 TB patients were included in the study. Age range was 15 to 59 years with mean age 37 ±15.9 years. HIV coinfection was found in 15 patients age range was 24 to 49 years with mean age 35 ±12.9 years

Table 1: HIV and TB coinfection

	HIV positive	HIV negative	Total
Total	15	85	100
Male	10	42	52
Female	5	43	48

In the present study, more than a half (*n*=10; 54.3%) of participants had CD4 count ranged between 200-500/µl and 21.6% (*n*=63) of respondents had CD4 count <200/µl. In addition, the study also showed that 29.2% (*n*=85) and 3.7% (*n*=11)

Of the 15 HIV positive diagnosed cases 5 were relapse case (33.33%) of which 2 were female and 3 were male . 10 cases (66.67%) were new cases of which 3 were female and 7 were male.

MDR TB (multidrug resistant TB) was seen in 10 cases of HIV co infected patients as compared to HIV negative it was 15 cases

Table 2: New and relapse cases

Sex	Male	Female
New cases	7	3
Relapse or old case	3	2
Total	10	5

Out of 15 diagnosed cases of HIV 3 were on ART while 12 were not taking any drugs. 1 case (male) was having CD4 count less than 200 while 5 cases were having count 200 to 500

DISCUSSION AND CONCLUSION

WHO Tuberculosis report shows that prevalence of tuberculosis has been declining globally; we are far away from achieving TB free world even in 2050[viii]. Also people living with HIV are most prone to contracting active TB because of the deficiency of immune response. It is envisaged that TB can affect young people in a disproportionate manner[ix].

In our study the age distribution showed the mean age of TB–HIV infection to be of 35 ±12.9 years. This is in accordance to findings of several other studies where the peak age of coinfection ranged from 31–40 to 41–50[x,xi]. In Thanh et al. study in Vietnam[xii] lower age group was reported,

The WHO global report shows that more TB cases and deaths occur among men compared to women. [xiii]in our study same results were found in which 5 female (33.33%) were having co infection as compared to men having 10 (66.67%). Atypical presentations like extra pulmonary TB and sputum smear-negative TB and atypical radiologic manifestations have been said to hamper the diagnosis of TB, thus, affecting the prompt treatment and control of the infection. Suchindran S reported high multidrug resistant TB in HIV patients [xiv].MDR TB (multidrug resistant TB) was seen in 10 cases of HIV co infected patients as compared to HIV negative it was 15 cases. One study reports a similar contrasting picture in which, even though the prevalence of extra pulmonary TB was 11–38%, it was higher in areas with the lowest HIV prevalence [xv].

Drug-resistant TB is becoming a significant challenge to the control of the infection in the world especially in HIV-positive patients[xvi].Treatment should be targeted at treating the immune suppression associated with HIV which promotes development of active TB. Previous history of TB, CD4 count less than 200/µl were the possible risk factors. Large-scale studies on the trends in TB/HIV co-infection and associated factors should also be implemented across the country.

ABSTRACT

Introduction: COPD is a common, preventable and treatable disease with increased disease burden accounting for significant mortality. A hallmark feature of COPD is the increased numbers of pulmonary neutrophils that can secrete a wide range of pro-inflammatory cytokines and chemokines as well as proteases that play role in the development of emphysema. We aimed to find out a simple, accessible and economical biomarker to prevent morbidity & mortality associated with COPD. Induced sputum is a non-invasive method that allows evaluation of neutrophil numbers in the airway lumen. **Methods:** A longitudinal comparative study involving 50 COPD patients with age, sex, race matched individuals were categorized into treatment group (Group1) and control group (Group2) underwent sputum induction and analysis to look for sputum neutrophil and its relation to COPD exacerbation and management. Response to treatment was measured using spirometry (FEV1, FEV1/FVC). **Observation:** We found out that 76% of the COPD patients had >70 Sputum Neutrophil count which persisted among 28% of the COPD patients despite treatment with macrolide. Most of the group 1 patients improved with macrolide treatment in addition to usual bronchodilators as shown by improvement in pre and post FEV1(p=0.001); compared to group 2 patients where there was no significant changes in pre and post FEV1(p=0.516). Sputum Neutrophil was significantly associated with improvement in CAT Score (p=0.009) and reduction in exacerbation(p=0.002). **Conclusion:** The author strongly concludes that sputum neutrophil count could prove to be one of the Significant biomarker to predict and manage the exacerbation of COPD.

KEYWORDS: COPD, FEV1, FEV1/FVC.

INTRODUCTION

COPD is currently the fourth leading cause of death in the world but is projected to be the 3rd leading cause of death by 2020. More than 3 million people died of COPD in 2012 (up from 2.4 million deaths in 1990) accounting for 6% of all death globally. COPD affects 329 million people or nearly 5 percent of the global population. It typically occurs in people over the age of 40. More than 90% of these deaths occur in the developing world. The number of deaths is projected to increase further because of higher smoking rates and an aging population in many countries. In the European Union, the total direct costs of Respiratory diseases are estimated to be about 6% of the total health care budget, with COPD accounting for 56% (38.6 billion Euros) of the cost of respiratory diseases. In the United States, the estimated direct costs of COPD are $32billion and the indirect costs $20.4 billion. It resulted in an estimated economic cost of $2.1 trillion in 2010. d treatable. COPD is a major cause of chronic morbidity and mortality throughout the world. Many people suffer from this disease for years, and die prematurely from it or its complications. COPD develops slowly.

Spirometry is used to confirm the diagnosis. Spirometry measures the amount of airflow obstruction present and is generally carried out after the use of a bronchodilator, a medication to open up the airways. Two main components are measured to make the diagnosis: the forced expiratory volume in one second (FEV_1), which is the greatest volume of air that can be breathed out in the first second of a breath, and the forced vital capacity (FVC), which is the greatest volume of air that can be breathed out in a single large breath. Normally, 75–80% of the FVC comes out in the first second and a FEV_1/FVC ratio of less than 70% in someone with symptoms of COPD defines a person as having the disease. Based on these measurements, spirometry would lead to over-diagnosis of COPD in the elderly. The Excellence criteria additionally require a FEV_1 of less than 80% of predicted.

However, there is a need for biomarkers that are reflective of the inflammatory mechanisms involved in disease pathogenesis. Such biomarkers may be useful for monitoring disease progression, evaluating the effects of therapeutic interventions or identifying disease sub-phenotypes with different clinical characteristics.

A hallmark feature of COPD is the increased numbers of pulmonary neutrophils that can secrete a wide range of pro-inflammatory cytokines and chemokines as well as proteases that play a role in the development of emphysema. Induced sputum is a non-invasive method that allows evaluation of neutrophil numbers in the airway lumen. The measurement of induced sputum neutrophils fulfils some of the ideal characteristics of a biomarker in COPD; neutrophils are thought to be mechanistically involved in disease pathophysiology, can be easily measured in the target organ using a non-invasive method, and are increased in patients with COPD compared to controls. There is a need to conduct large cohort studies to further explore the potential utility of this biomarker in COPD patients.

The use of sputum in research has improved our understanding of airway diseases in many ways because it is noninvasive (in the case of spontaneous sputum) or relatively noninvasive (with induced sputum), and cell counts in sputum have the qualities of excellent and highly reproducible measurements that are accurate and sensitive and identify the presence, type, and severity of airway inflammation. These measurements can be obtained repeatedly and in exacerbations, as well as in all severities of disease. Induced sputum, in particular, has been shown to be a highly effective method for determining the inflammatory processes in the airways (Gibson et al 1989; Pizzichini et al 1996; Pizzichini et al 1997; Jayaram et al 2000). Increasingly, sputum induction has been used in clinical and research settings to study airway inflammation in both asthma and COPD (Fahy et al 1993; Keatings and Barnes 1997; Wielders and Dekhuijzen 1997; Rutgers et al 2001).

Sputum analysis can also be used to determine the inflammatory response to inhaled glucocorticosteroids. Indeed, a single large dose (2400 μg) of inhaled budesonide was shown to result in a reduction in sputum eosinophil numbers 6 hours after administration (Gibson et al 2001).

In COPD, the most common sputum change is neutrophilia and increased products of neutrophil activation, including proteases, myeloperoxidase, and elastase (Chung 2001; Williams and Jose 2001; Kim and Nadel 2004; O'Donnell RA et al 2004). In cigarette smokers with COPD, the degree of neutrophilia is loosely related to the degree of chronic airway obstruction (Stanescu et al 1996). This suggests that sputum neutrophils or their products may be used as early markers of the manifestation of COPD.

AIMS AND OBJECTIVES

Objectives

1. To study prevalence of Sputum Eosinophilia and Neutrophilia in Chronic Obstructive Pulmonary Disease (COPD)
2. To study prevalence of Sputum Eosinophilia and Neutrophilia in Different COPD GOLD groups
3. To study prevalence of Sputum Eosinophilia and Neutrophilia in Response to COPD Treatment

MATERIALS AND METHOD

Patient Selection

We performed a longitudinal comparative study to evaluate sputum analysis in all diagnosed COPD patients who attended the Department of TB and respiratory diseases, SS Hospital, IMS, BHU.

If not previously documented/tested, all such patients were documented for COPD with post bronchodilator pulmonary function test confirmation (FEV1 / FVC < 0.7) with irreversible airway obstruction and were screened for other causes of breathlessness like exacerbation of Bronchial Asthma, Interstitial lung diseases, worsening of Dyspnea due to heart failure etc., by channeling through detailed history, thorough physical examination and a battery of relevant investigations. Data on demographic characteristics, sleep, medical history, medication use, and habits were obtained with the use of a modified standardized questionnaire.

Inclusion criteria

- Patients with COPD.
- Age 41 to 85 year.
- Patients as well as attendants willing to give informed consent.
- Patients ready to undergo necessary investigation.

Exclusion criteria

- Patients with multiple organ failure.
- Clinical features and spirometry suggestive of disease other than COPD.
- Haemodynamic instability.
- Those patients who are not giving consent.
- Women who are pregnant or currently lactating.
- Mixed and restrictive pattern of lung function in spirometry.
- Could not perform spirometry correctly.

The institutional ethics committee was asked to approve the protocol, informed consent was obtained from the participants.

Study Size

We did Sputum analysis of 50 COPD patients which were attend outdoor or indoor of our department. All patients included in study underwent evaluation as per pre-standardized protocol**.**

RESULTS AND OBSERVATION

A total of 50 COPD patients with age, sex, race, BMI matched were enrolled into the study, between 40 to 85 years of age group which were chosen from the OPD and ward of TB & Respiratory Diseases of Sir Sunderlal Hospital, BHU Varanasi**.**

In our study, out of 50 subjects in group I, 6 (24%) had Eosinophilia and 18 (72%) had Neutrophilia and in group II, 5 (20%) had Eosiniphilia and 20 (80%) had Neutrophilia. Earlier studies by Singh et al. (2010), total 359 subjects produced an evaluable sample at baseline, and 297 subjects after 1 year.

The researcher also found out that most of the patient in Group 1 fell into GOLD 3(n=12) and GOLD 2 (n=6) prior to initiation of treatment with macrolide compared to post treatment in GOLD 3 (n=10) and GOLD 2(n=15). However in Group 2, most of the patient fell into GOLD 3(n=11) and GOLD 2 (n=10) compared to post treatment in GOLD 3 (n=7) and GOLD 2 (n=13). Our findings were similar to Singh et al. where half of the subjects were GOLD stage 2, with the remaining subjects being GOLD stage 3 or 4. Another study conducted by Stanescu et al. (1996) suggested In cigarette smokers with COPD, the degree of neutrophilia is loosely related to the degree of chronic airway obstruction. This suggests that **sputum neutrophils or their products may be used as early markers of the manifestation of COPD**

The researcher also showed that 22% (n=11 out of 50) of the COPD patients had ≥ 3% Sputum eosinophil count and 78% (n=39 out of 50) had < 3% sputum Eosinophil. The lower sputum eosinophil may be due to treatment with ICS/oral steroid.

The researcher found out that 22% of the participants had sputum Eosinophil ≥ 3% compared to most literatures which states that 40% of patients with COPD have eosinophilic airway inflammation.

The researcher also found out that **76% of the COPD patients had neutrophilic airway inflammation with sputum Neutrophil > 70**%. According to **Hoenderdos**, and **Condliffe** et al. Neutrophilic inflammation predominates in the COPD airway wall and lumen, but, despite the presence of abundant innate immune cells, the progressive clinical course of the disease is punctuated by recurrent infection-driven exacerbations.

The Researcher also found out that increased sputum Neutrophil was associated with decline in lung function (FEV1) which is similar to the finding by Singh et al, who concluded that Sputum neutrophil measurements in COPD are associated weakly with FEV_1 % predicted and health status.

Table 4-1a: Prevalence of Sputum Eosinophil in COPD Patients Prior to Treatment.

Eosinophil (PRE)	No. of patients	Percentage
≥3%	**11**	**22**
< 3%	**39**	**78**
Total	**50**	**100**

Table 4-1a, showed that 22% (n=11 out of 50) of the COPD patients had ≥ 3% Sputum eosinophil count and 78% (n=39 out of 50) had < 3% sputum Eosinophil. The lower sputum eosinophil may be due to treatment with ICS/oral steroid.

Table 4-1b: Prevalence of Sputum Neutrophil in COPD Patients Prior to Treatment.

Neutrophil (PRE)	No. of patients	Percentage
>70	**38**	**76**
≤70	**12**	**24**
Total	**50**	**100**

Table 4-1b, showed that 76% (n=38 out of 50) of the COPD patients had > 70 Sputum Neutrophil count and 24% (n=12 out of 50) had ≤ 70 sputum Neutrophil.

Table 4-2a: Prevalence of Sputum Neutrophil in COPD Patients Prior to Treatment.

Gold Stage Pre	No. of patients	Percentage
≥80	**3**	**6**
50-79	**16**	**32**
30-49	**23**	**46**
<30	**8**	**16**
Total	**50**	**100**

Table 4-2B: Prevalence of Sputum Neutrophil in COPD Patients Post Treatment.

Gold Stage Post	No. of patients	Percentage
≥80	**1**	**2**
50-79	**28**	**56**
30-49	**17**	**34**
<30	**4**	**8**
Total	**50**	**100**

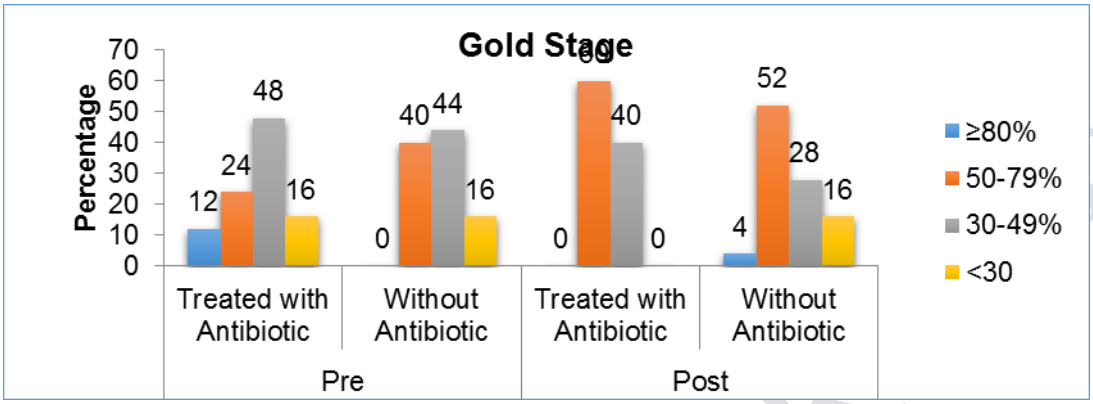

Figure 4-2a: Prevalence of Sputum Neutrophil in COPD Patients Pre and post Treatment.

Table 4-2a/4-2b and figure 4-2 showed maximum number of COPD patients in GOLD 3 (n=23 in pre treatment Vs n=17 aftertreatment) followed by G0LD 2(n=16 prior to treatment vs n=28 after treatment), followed by GOLD 4 (n=8 in pre treatment vs n=4 post treatment).

Table 4-3a: Prevalence of Sputum Eosinophil in COPD Patients after Treatment.

Eosinophil Post	No. of patients	Percentage
≥3%	**7**	**14**
< 3%	**43**	**86**
Total	**50**	**100**

Table 4-3a, showed that 14% (n=7 out of 50) of the COPD patients had ≥ 3% Sputum eosinophil count and 86% (n=43 out of 50) had < 3% sputum Eosinophil. The further decline in sputum eosinophil may be due to treatment with ICS/oral steroid.

Table 4-3b: Prevalence of Sputum Neutrophil in COPD Patients after Treatment.

Neutrophil Post	No. of patients	Percentage
>70	**14**	**28**
≤70	**36**	**72**
Total	**50**	**100**

Table 4-3b, showed that 28% (n=14 out of 50) of the COPD patients had > 70 Sputum Neutrophil count and 36% (n=36 out of 50) had ≤ 70 sputum Neutrophil. There is a significant decrease in Neutrophil count after treatment with Macrolide.

Table 4-4: Comparison of Severity of COPD in Group 1 Vs Group 2.

SUMMARY AND CONCLUSION

1. The author strongly concludes that sputum neutrophil count could prove to be one of the Significant biomarker to predict and manage the exacerbation of COPD.
2. The researcher found out that most of the patients with COPD (76%) had increased Sputum Neutrophil count.
3. COPD patients with increased Sputum Neutrophil count was associated with worsening of lung function and as well as CAT Score. Neutrophilic airways were less responsive to steroid compared to eosinophilic airway diseases.
4. After Treatment with macrolide in addition to LABA+LAMA+ICS, there was an improvement in lung function and sign and symptoms as revealed from CAT Score.
5. Sputum Neutrophil may be used as a biomarker for predicting future worsening and deteriorating lung function.
6. Sputum Eosinophil was increased in 22% of COPD patients and it could also be used as one of the biomarker for COPD progression, exacerbation.
7. The researcher also found out that number of exacerbation was significantly increased in patients with increased sputum Neutrophil and eosinophil count.
8. However, eosinophilic airway disease as evident from our study was associated with better lung function and improved responsiveness to therapy (ICS).
9. The Researcher also found positive correlation of Sputum Neutrophil with CAT Score in patients with COPD i.e. CAT score improved with improvement in Sputum Neutrophil count.

A Comparative Evaluation of Rapid Card Test with Enzyme- Linked Immunosorbent Assay for the Detection of HBsAg Among Pregnant Women in a Tertiary Care Hospital

Megha Sharma[1], Saroj Golia[2], S.K. Mehra[3], Manoj V Jani[4]*

[1]Assistant Professor; [2]Professor & Head, Department of Microbiology, [4]Assistant Professor, Department of TB & Chest, Ananta Institute of Medical Sciences Research Centre, Rajsamand [3]Ex- Professor & Head, Department of Microbiology, Geetanjali Medical College & Hospital, Udaipur

ABSTRACT

Background: *Hepatitis B virus infection is an important health problem and a leading cause of death worldwide. The most important marker for HBV infection is HBsAg. A proper identification of kit is required for proper diagnosis of infection, as well as disease management and prevention.* ***Aims& Objective****: - The aim of the present study was to compare rapid HBsAg detection ICT kits for the screening of HBV infection with gold standard ELISA method.*
Methods: *The study comprised 500 blood samples of pregnant women. These samples were tested with ICT kits of (Hepa Card Company) and ELISA (HEPLISA by J. Mitra.).* ***Results:*** *In present study we found 100% sensitivity, 99.59% specificity, 81.81% positive predictive value ,100%Negative predictive value and 99.60% diagnostic efficiency of rapid card test with comparison to ELISA for HBsAg detection.* ***Conclusion****: The present study concluded that the overall performance of the rapid ICT kit for HBsAg was equally sensitive to ELISA and yet they were cheap and quicker. It can be recommended that ELISA comparable rapid devices may be allowed to be used for preliminary screening of HBsAg especially in remote areas or where cost is an issue.*

Keywords: *HBsAg, Immunochromatographic kit ICT, ELISA, comparison for effectiveness.*

INTRODUCTION

Hepatitis B virus (HBV) infection has been one of the leading causes of hepatocellular carcinoma not only globally but in India also. India has an intermediate prevalence of Hepatitis B with a 4% to 5.4% HBsAg positive population.[1] In order to prevention of HBV transmission the Global Advisory Group to the world Health Organization (WHO) recommended that all countries integrate the Hepatitis B vaccine into national immunization programs. With respect to it the Hepatitis B vaccine has been introduced into national Immunization program in India. India has introduced the Hepatitis B vaccine into the routine childhood vaccination schedule. A recent report of Dwivedi et al[1] in India, suggested that there may be a significant role of vertical transmission in Hepatitis B infection.[2] Screening of HBV infection by detecting Hepatitis B virus surface antigen (HBsAg) in every pregnant woman has been practiced in India to prevent perinatal transmission. Also screening for HBsAg before vaccination and blood transmission has been practiced in India. It has been estimated that 350 million people worldwide are chronic carriers of Hepatitis B virus.[3] High risk of death form livers cirrhosis and hepatocellular carcinoma occur in these chronic carriers of Hepatitis B.[4,5] HBV infection is spreading rapidly in developing countries due to lack of health education, illiteracy, poverty, lack of awareness of the need of HBV vaccination.[6] It is therefore important for individuals to

undergo screening for HBV before blood donation, in pregnancy, high risk infants for ensuring prompt treatment and avoidance of transmission. Early and accurate detection of HBV infection using sensitive and specific methods allow investigators to evaluate the status of HBV infection and develop strategies to prevent transmission. Also, a highly infectious virus like HBV which causes silent infection, accurate detection of the virus marker is essential for controlling the transmission of the virus that is why it is required to validate detection methods prior to allowing their use in diagnostic laboratories. HBsAg rapid card test is a rapid screening test for the qualitative detection of HBsAg in whole blood, serum or plasma specimen. The test utilizes a combination of monoclonal and polyclonal antibodies to selectively detect elevated levels of HBsAg in whole blood, serum or plasma.[7] While ELISA is an enzymatic immunoassay technique of the "sandwich" type for the detection of HBV in human serum or plasma. The test uses monoclonal antibodies selected for their ability to bind themselves to the various subtypes of HBsAg now recognized by the World Health Organization (WHO)[8] and the most part of variant HBV strains.[9]

Different methods are used for the diagnosis of Hepatitis including ICT, ELISA, EIA and PCR. ELISA, EIA and PCR methods are expensive and are used in well equipped laboratories and major tertiary care hospitals. Rapid diagnostic kits are a good choice as they are less expensive and do not need high technical manpower or infrastructure[10]. In India, they are found useful in resource limited setting and as a point of screening tests, making them widely popular for HBsAg detection. The rapid card test is known to have less sensitivity and specificity than ELISA but some have sensitivity and specificity comparable to ELISA.[11] Ideal rapid screening tests should have a high degree of sensitivity and a reasonable level of specificity to minimize false positive and false negative results. The aim of present study is to check the sensitivity and specificity of rapid card test of HBsAg which are frequently used in different laboratories and hospitals, nursing homes, camps and to compare with gold standard method ELISA. Goal of this study is to recommend a reliable and cost effective test for diagnosis of HBV in a developing country like India where advance diagnostic facilities are not available everywhere.

METHODS

Collection of specimen- A prospective study was conducted from August 2015- Jan 2016 in a tertiary Care hospital at Udaipur, Rajasthan, India. A total of 500 pregnant women blood samples were collected after obtaining an informed consent and were tested for HBsAg in department of Microbiology at Hospital. Sample Processing- Each blood sample was tested for HBsAg using both rapid card test (Hepacard Diagnostic enterprises) and ELISA by Hepalisa-J.Mitra & Co. Pvt. Ltd method.)

Rapid card Test process

Hepacard is one step immunoassay based on antigen capture or sandwich principle. The method uses monoclonal antibodies conjugated to colloidal gold and polyclonal antibodies immobilized on a nitrocellulose strip in a thin line. The test sample is introduced to and flows laterally through an absorbent pad where it mixes with the signal reagents. If the sample contains HBsAg, the colloidal gold-antibody conjugate binds to the antigen, forming an antigen-antibody-colloidal gold complex. The complex then migrates through the nitrocellulose strip by capillary action. When the complex meets the line of immobilized antibody (test line) 'T', complex is trapped forming an antigen-antibody colloidal gold complex. This forms a pink band indicating the sample is reactive for HBsAg. To serve as a procedural control, an additional line of antimouse antibody (control line)'C', has been immobilised at a distance from the test line on the strip. If the test is performed from the test line on the strip then the test is performed correctly, this will result in the formation of a pink band upon contact with the conjugate.[12]

ELISA Method

Hepalisa is a solid phase enzyme linked immunosorbent Assay based on the direct sandwich ELISA principle. The microwells are coated with monoclonal antibodies with high reactivity for HBsAg. The samples are added in the wells followed by addition of enzyme conjugate (polyclonal antibodies) linked to horseradish peroxide (HRPO). A sandwich complex is formed in the well where in HBsAg (from serum complex is formed in the well wherein HBsAg (from serum sample) is "trapped" or "sandwich" between the antibody and antibody HRPO conjugate. Unbound conjugate is washed off with wash buffer. The amount of bound peroxidise is proportional to the concentration of HBsAg present in the samples. Upon addition of the substrate buffer and chromogen, a blue colour develops. The intensity of developed blue colour is proportional to the concentration of HBsAg in sample. To limit the enzyme –substrate reaction stop solution is added and a yellow colour develops which is finally read at 450nm spectrophotometrically.

RESULTS

Out of 500 blood samples tested on rapid card tests, 9 samples were positive, and 491 were negative for HBsAg by rapid card test. On further testing with ELISA, 2 false positive were detected. Using ELISA as a gold standard confirmatory method sensitivity of rapid card was 100%, specificity was 99.59%, positive predictive value was 81.81%, negative predictive value was 100%, and diagnostic accuracy was 99.60%.

Table 1: Comparison of rapid card test with ELISA, (n=500)

	Rapid card	ELISA
Positive	9	7
False Positive	2	0
Negative	489	493
False Negative	0	0

Table-2 Evaluation of Rapid test kits with ELISA

HBsAg test	Sensitivity	Specificity	Positive Predictive value	Negative Predictive value	Diagnostic efficiency
Rapid Card Test	100%	99.59%	81.81%	100%	99.60%
ELISA	100%	100%	100%	100%	100%

DISCUSSION

In the present study rapid kits were compared with gold standard ELISA for screening of HBsAg. ELISA and rapid test kits are equally sensitive yet rapid kits are cheaper than the prior one. Rapid tests enable early detection at sites

where laboratory facilities or trained manpower are not available. The high laboratory cost for screening of HBsAg among the poor population is also sought as the rapid card tests are cheaper in diagnosis of HBsAg. Ideally rapid devices should have a high degree of sensitivity and a reasonable specificity so as to minimize false positive and false negative results.

In our study, the sensitivity of rapid test kit was 100% and specificity was 99.56%. Yogendra K.Tiwari et al[13] reported sensitivity of rapid kit test as 95.12% and specificity 99.82%. Another study by Kaur et al[14] reported 100% specificity and 94.4% sensitivity of ELISA to pick up all false negative. A study by Akhtar et al [15] showed 100% sensitivity of rapid card test kit with specificity of 91.7% for HBsAg. Ansari et al[16] showed that rapid assays with strip or devices had sensitivity between 97.5% and 99.2% and specificity between 97.25% and 99.2%. A study conducted by Lin et al[17] by using two ICTs the sensitivity and specificity was 100% respectively. A study from Karachi, Pakistan showed comparable sensitivity and specificity of ICT kit and ELISA techniques[18], followed by another study from Seoul[19] showed 97% sensitivity and 100% specificity for detecting HBsAg. Few variance results were seen in a study conducted by Khanet al[20] found sensitivity 53% and specificity was 100% for HBsAg rapid card. Ideally rapid devices should have a high degree of sensitivity and a reasonable specificity to minimize false positive and false negative results. False positive in our study was 18.19% and false negative as nil. Tiwari et al[13] came with a result of 4.88% as false positive and 0.18% as false negative similar to Gul et al.[21] Rapid ICT kits giving more false positive result are better for diagnosis than those that give more false negative results.[22] A positive result can be followed by more accurate and advance method to confirm the infection presence unlike a negative result. Hence choosing a test with high sensitivity and Negative predictive value is more important than choosing a test with high specificity and positive predictive value for routine use. In a study conducted in India by Maity et al[23], a comparative study, 3 different HBsAg ICT kits Hepacard, Crystal and SD bioline, were evaluated, all of them showing 100% sensitivity and 100% specificity. Immunochromatography based rapid assays used for HBsAg detection may not have the same accuracy indices in every region due to the differences in the prevalence of HBV infection in a given population. The prevalent subtype of HBV infecting a population can be different. Some ICT kits may not detect certain subtype of HBV giving false negative results.[24,25.] ICT for HBsAg detection must be validated before being used in resource limited settings. Further failure of rapid test kit to detect HBV reactive samples may be due to inadequate coating of the antigen, different nature of antigen used and genetic heterogeneity of the virus prevalent in that area.

CONCLUSION

The present study demonstrate that ICT based rapid test devices are suitable to be used as a screening test for Hepatitis B surface antigen as at a point of care test and should be recommended only in resource limited poor settings, remote areas and peripheral health facilities for screening purpose. But threat of silent transmission and spreading of diseases among people create an urge for more accurate diagnostic method such as ELISA.

ABSTRACT

Background: *Hepatitis B virus infection is a major global health problem and India accounts for 10-15%of the entire pool of HBV carriers of the world. Prevalence of Hepatitis B in pregnant women worldwide is 2.5 to 1.5%, whereas in India it is 2 to 7%. Hepatitis B virus is a double stranded DNA virus. The study was undertaken to determine the seroprevalence of Hepatitis B among the pregnant women in southern part of Rajasthan at a rural based tertiary care teaching hospital.* ***Methods:*** *This is a prospective study conducted at a tertiary care hospital, Udaipur, Rajasthan, from August 2015 to December 2017.Blood samples were collected from 1011 pregnant women with age ranging from 15-45 years. Screening of HBsAg was done by RPHA method and positive HBsAg tests were confirmed by ELISA. The data of those , who were found to be positive for HBsAg was statistically analyzed with the chi square tests, and results were considered significant if the p value was <0.05.*

Results: *The overall HBsAg seroprevalence rate was 1.28%, among the total 1011 pregnant women included in this study. HBsAg seroprevalence was highest, (1.64%) in 15-25 years of age group, and 1.71% in the second trimester of pregnancy. The correlations of seroprevalence rate of HBsAg among selected age groups and according to second trimester of pregnancy were not found statistically significant. (p value>0.05)*

Conclusion*: In this study the seroprevalence of Hepatitis B surface antigen was 1.28%. To prevent vertical transmission in the pregnant women, they should be screened for HBsAg at the first antenatal visit for appropriate management.*

Keywords: *Hepatitis B surface antigen, pregnant women, Vertical Transmission*

INTRODUCTION

Hepatitis B Virus (HBV) infection is one of the most common public health problems. India has over 40 million hepatitis B virus carriers accounting for 10-15% of the entire pool of HBV carriers of the world.[1,2] However, the epidemiology and pattern and consequence of HBV infection varies greatly from one part of the world to another also changes with time. Hepatitis B is caused by double stranded DNA virus belonging to hepadnaviridae family. It leads to acute hepatitis and may also have serious complications like acute and chronic hepatitis, cirrhosis and hepatocellular carcinoma.[3-5] Hepatitis B Virus infection during pregnancy, is associated with a high risk of maternal complications. Prevalence of hepatitis B in pregnant women worldwide is 2.5 to 1.5%, whereas in India is 0.2 to 7.7%[6] Ten percent of infants born to women with acute HBV infection during the first trimester of pregnancy are HBsAg positive at birth, and 80 to 90% of neonates become HBsAg positive without prophylactic therapy, if acute maternal infection develops during the third trimester of pregnancy.[7,8] Screening and evaluation of hepatitis during the pregnancy is much more important to prevent mortality of mother and child. However there is a scarcity of systematic information on the prevalence of HBV infection among pregnant women in India including the study area. This will be useful to address the current prevalence status of hepatitis B during pregnancy, the present study aimed to determine the seroprevalence of hepatitis B surface antigen among pregnant women. The risk factors of Hepatitis B infection like IV drugs, previous Blood transfusion history, previous surgeries, tattooing, piercing etc were also

evaluated, which would provide information to institutional and public measures to reduce the transmission of infection.

METHODS

The present study was undertaken over a period of one and half year from August 2015 to December 2017, approved by the institutional Ethics Committee. The present study was conducted at a rural based tertiary care teaching hospital at Udaipur district of Rajasthan. A population of 1011 pregnant women age ranging from 15-45 years attending Antenatal clinic was involved in the study. Individuals were interviewed by structured questionnaire including data regarding obstetric history, previous HBV vaccination, HBsAg status of self and spouse and the associated risk factors of infection were also asked.

Laboratory Assay: About 2 ml of venous blood was collected from each individual after obtaining a written consent under strict aseptic precautions. Rapid immunochromatography test (HEPA card) was employed to detect the presence of HBsAg. For confirmation, blood samples tested positive for HBsAg were subjected to commercially available fourth generation ELISA (Enzyme Linked Immunosorbent Assay) Kit Hepalisa by J. Mitra & Co. Pvt. Ltd with antigen sensitivity 0.1ng/ml was used. Manufacturer's instructions were followed during the entire test procedure.

RESULTS

A total of 1011 pregnant women attending antenatal clinic in a tertiary care hospital, were studied. All the women were asymptomatic and were unaware of Hepatitis B status. The subject age ranges from 15-45 years. The seroprevalence of HBsAg positivity in this current study was 1.28% among 1011 participants 13 women tested positive for HBsAg. Age distribution and HBsAg screening tests were given in Table1. In statistical analysis, the p-value obtained was >0.05 (statistically insignificant). The distribution of trimester of pregnancy and HBsAg screening results were given in Table 2. The p value obtained was >0.05 which is statistically insignificant. Analysis of age distribution of HBsAg positive women revealed a high prevalence (1.71%) among 15-25 years majority of them were primigravidae in second trimester of pregnancy. Associated risk factors distribution among HBsAg positive women was shown in Table 3.

Table 1:- Age wise distribution and HBsAg status (n=1011)

Age	Number tested	HBsAg positive	HBsAg negative
15-25	364	6(1.64%)	358 (98.35%)
26-30	384	4 (1.04%)	380 (98.95%)
31-35	208	3(1.44%)	205 (1.44%)
36-40	47	0	47(100%)
41-45	8	0	8(100%)
Total	1011	13	998

Table 2:- HBsAg seropositivity in different trimesters of pregnancy (n=1011)

Trimesters	No of Pregnant women	HBsAg positive (%)
First	243	3 (1.23%)
Second	467	8(1.71%)
Third	301	2 (0.66%)

Table-3 Risk Factors observed in HBsAg Positive women (n=13)

Risk Factors	No of ANC
History of Blood Transfusion	3(23.07%)
Previous Surgeries	2 (15.38%)
HIV status	0
Tattooing	4 (30.76%)
Piercing	13(100%)

DISCUSSION

The prevalence of HBsAg varies widely in different parts of the India. The variety of socioeconomic status of the population studied, genetic factors, and other risk factors contribute to the variance of seroprevalence rate. The prevalence of HBsAg positivity in pregnant women has been reported to range from 2.61-6.3% in various studies.[9-12] In our study, the overall seroprevalence of HBsAg positivity in pregnant women 1.28%, was in accordance with a seroprevalence of 1.1% reported by Pande et al[13] and also comparable to the seroprevalence 1.15% by Ambade et al.[14] Dwivedi et al[15] study shows the declining seroprevalence of HBsAg 0.91. Few other studies from India by Chatterjee et al[16] (0.82%) and Shazia Parveen S. et al[17](0.61%), the seroprevalence rate reported were lower than the present study. Other studies from India as carried out by Mittal et al,[18] Gill et al,[19] Nayak et al,[20] and Khakhkhar Vipul et al,[21] reported higher seroprevalence rate of 6.3%, 5%, 3.7% and 3.07% respectively in comparison of our study. Also, the seroprevalence of HBsAg among pregnant women in our study can also be comparable with 1.6%, 1.47% and 1.37% as reported in some countries respectively like Saudi Arabia,[22] Turkey[23] and Pakistan.[24] Regarding age, in the present study, high HBsAg seropositivity rate in pregnant women was found in age group of 15-25 years (1.64%) in agreement with Ambade et al, Dwivedi M et al and Khakhkhar Vipul et al, and smita Thakkarwad et al.[25] In our study highest seroprevalence of HBsAg positivity was found in second trimester 1.71%. This was with comparable studies of Padmavati Palange et al[23] and Mehta et al[26] and variance with the findings from similar works, Dwivedi M et al and Khakhkhar Vipul et al, and smita Thakkarwad et al.[25]

CONCLUSION

This study provides necessary information to detect the risk factors to formulate necessary preventive measures. The HBsAg seropositivity rate of 1.28% in pregnant women in this study recommends and supports an appropriate antenatal screening, so that the vertical transmission of Hepatitis B virus infection can be avoided. Public health policies should include routine universal screening of HBV infection and immunization of risk infants immediately after birth.

ABSTRACT

Background: *Respiratory infections among critically ill Patient are associated with high morbidity and mortality. Mechanically ventilated patients are at a high risk of acquiring respiratory infections due to complex interplay between the endotracheal tube, host immunity and virulence of invading bacteria. Irrational use of antibiotics increases the emergence of drug – resistant bacteria.* ***Objectives:*** *The aim of study was to investigate the bacterial isolates in the endotracheal aspirates of mechanically ventilated patients in ICU and see the antimicrobial resistance pattern of bacterial isolates.*

Methods: *Analysis of E.T aspirates of 459 patients over a period of 1 year (Aug 14 to Aug 15) was done. Aspirates were cultured on Blood and MacConkey agar isolation and identification was done using conventional techniques and biochemical reactions. Antibiotic sensitivity testing was done by Kirby-Bauer disc diffusion method as per CLSI guidelines.* ***Results:*** *Out of 459 Samples 365 was found to be positive. Acinetobacter sp (44.65%) was the most common isolate followed by Klebsiella sp (18.63%), Pseudomonas sp (11.23%), Candida (10.46%), Escherichia Coli (7.94%), COPS (3.28%), CONS (2.46%), Enterococci (0.82%), and Citrobacter (0.54%). The gram-negative bacilli were mostly sensitive to Tigecycline, Colistin, Imipenem, Meropenem, Amikacin and Piperacillin/Tazobactam. Gram positive Cocci were mostly sensitive to Vancomycin, Linezolid and Gentamicin.*

Conclusion*: The isolation and antimicrobial resistance pattern of the microorganisms is necessary for their effective management. Endotracheal intubation is one of the major risk factors in causing iatrogenic infections to patients. A local antibiogram for each hospital, based on bacteriological patterns and susceptibility is essential to initiate empirical therapy.*

Keywords: *Endotracheal aspirates, ventilated patients, antibiogram of bacterial isolate*

INTRODUCTION

Mechanical ventilation is a life-saving procedure for many patients in intensive care unit. Patients who are intubated and mechanically ventilated are further at a high risk of acquiring respiratory infections due to complex interplay between the endotracheal tube, host immunity and virulence of invading bacteria which may lead to ventilator associated pneumonia (VAP).Tracheal colonization of different bacteria may be responsible for added or super infections and at the same time, increases the risk of mortality[1]. The etiological agents may vary according to the population of patients in ICU, duration of hospital stay, pre-existing and prior antimicrobial therapy.

To add to the trouble, the statistical data and evidences from research prove that multi drug resistance bacteria are rapidly emerging across the world and pose a big challenge to health care system. Extensive and non-specific use of broad-spectrum antibiotics in hospitalized patients has led to both increased carriage and the development of multi drug resistant strains.[2] Multi drug resistance bacteria cause serious nosocomial and community acquired infections that are hard to eradicate. One must use existing antibiotics skillfully and more judiciously. It is difficult to manage these infections effectively unless we are armed with adequate and good quality data about the antibiotics susceptibility pattern of organisms causing respiratory infections among mechanically ventilated patients in intensive care unit. To be more effective this data has to be region specific and also

Source of Support: Nil, **Conflict of Interest:** None

has to be updated regularly as bacterial susceptibility varies with time and space. Unfortunately, such data is scanty, and this has led to a wide spread of mortality and morbidity due to respiratory infections. Therefore, updated knowledge of local epidemiology and susceptibility profile is recommended for guiding the clinicians regarding empirical choice of antibiotics and should become mandatory along with adequate clinical diagnosis and bacterial confirmation.[3]

Hence, the study was planned to identify pattern of bacterial isolates responsible for respiratory tract infections among mechanically ventilated patients at intensive care unit and to make their antimicrobial resistance pattern.

Aims & Objectives:

1. To study the microorganism's profile in the ICU during the study period in endotracheal tube culture.
2. To study the antibiotics to which these microorganisms are susceptible.
3. To propose a proper empirical antibiotic therapy in intubated patients according to prevalence of microbiological organisms in ICUs.

METHODS

The prospective study was carried out with the samples of endotracheal aspirates and endotracheal tube tip received from ICUs in the microbiology laboratory over a period of one year (Aug-2014 – Aug-2015). Samples were collected under sterile conditions from patients admitted in both medical and surgical intensive care unit who were ventilated for at least 48 hrs.

Collection of Specimen:

Endotracheal Aspirate: Sampling was done by introducing a catheter aseptically through the endotracheal tube and secretions aspirated into a sterile syringe.

Endo-tracheal tube tip: The endo-tracheal tube tip was cut aseptically into a sterile container and sent to the Microbiology laboratory.

Processing of Specimen:

Endotracheal Aspirate*:*

Both 10µl of the specimen and 1 µl of the specimen was inoculated in blood agar and MacConkey agar.

Endotracheal tube tip: The lumen of endotracheal tube tip was rinsed with 0.5 ml of sterile normal saline. 10µl of the fluid was inoculated on blood agar and MacConkey agar. A gram's stain of the endotracheal secretions / endotracheal tube tip fluid was done to assess the number of pus cells and the presence of bacteria. A semi quantitative method was followed, and plates were incubated overnight at 37°C.13. The organisms isolated were identified based on colony characteristics on Blood agar and MacConkey agar, Gram's stain, Biochemical reactions by using standard microbiological techniques. Isolates identified as commensals or contaminants were excluded from further process. A Kirby-Bauer method was used to test the susceptibility of organisms to various antibiotics. As per Clinical and Laboratory Standards guideline (2014).[4]

Antibiotics used:

Ampicillin/Sulbactam (AS-10/10µg), Cefuroxime (CXM-30µg), Cefoxitin (CX-30 µg), Ceftriaxone(CTR-30µg),Vancomycin (VA-30µg), Linezolid (LZ-30µg), Piperacillin/Tazobactam (PIT-100/10µg), Ceftazidime/Clavulanic acid (CAC-30µg/10µg), Cefotaxime/Sulbactam (CFS-5/30µg), Cefepime (CPM-5µg), Ceftriaxone (CTR-30µg),Gentamicin (GEN-10µg), Amikacin (AK-30µg), Aztreonam (AT-30µg),Azithromycin- AZM-15 µg), Ciprofloxacin (CIP-5µg), Levofloxacin-(LE5µg), Amoxicillin/Sulbactam (A/S-30µg), Imipenem (IMP-10µg), Colistin (CL-10µg), Meropenem (MRP- 10µg), Polymyxin B (PB-300U), Tigecycline (E- strip).Zone diameter was measured and interpreted as per the Clinical and Laboratory Standards Institute(CLSI) guidelines (2014)[4].

RESULTS

A total of 459 samples were collected from 459 patients during the study period of one year. Out of 459, 94 samples were either sterile or were polymicrobial growth which were not processed further for the study. Among 365, 184 samples (50.4%) were of male and rest were of female181 (49.58%). The organism isolated were *Acinetobacter sp*. 163 (44.65%), *Klebsiella sp* 68 (18.63%), *Pseudomonas sp* 41 (11.23%), *Escherichia Coli* 29 (7.94%), *Candida* 38 (10.41%), *Coagulase Positive staphylococcus aureus* (COPS)12 (3.28%), *Coagulase Negative Staphylococcus aureus* (COPS) 9 (2.46%), *Enterococci* (0.82%), and *Citrobacter* 02 (0.54%)

Acinetobacter was the most resistant of all other isolates. It was sensitive to Tigecycline (98.15%), Colistin (96.9%0, Meropenem (94.4%), Imipenem (92.02%), followed by Amikacin 36.80%, Levofloxacin 30.6%, Piperacillin/Tazobactam (25.7%), Ciprofloxacin 25.15%. (table-2).

Table 1: Micro-organisms isolated and percentage (n=459)

Micro-organisms	%
Acinetobacter sp	163(44.65%)
Klebsiella sp	68(18.63%)
Pseudomonas sp	41(11.23%)
Candida	38(10.46%)
Escherichia Coli	29(7.94%)
Citrobacter	2(0.54%)
Coagulase Negative Staphylococci (CONS)	9(2.46%)
Coagulase Positive Staphylococci (COPS)	12(3.28%)
Enterococci	3(0.82%)
No growth	94
Total	459

All isolates of Pseudomonas sp were sensitive to Imipenem 100%, Meropenem 100%, Tigecycline 100%, Colistin 100%, Polymyxin-B 100%, followed by Amikacin 68.2%, Piperacillin/ Tazobactam 68.2, Levofloxacin 56.09%. (table-2).

All Klebsiella sp were 100% sensitive to Tigecycline and Colistin followed by Imipenem 86.76%, Meropenem 88.2%, Levofloxacin 23.5%, Amikacin 35.29%, Piperacillin/Tazobactam 19.11, Ciprofloxacin 11 (16.17%). Other drugs were 7.3% sensitive were highly resistant with sensitivity of 7.3% (Ceftazidime/ C.A, Cefotaxime/ Sulbactam, Cefepime, Ceftriaxone) (table-2).

Similarly, all strains of Escherichia Coli were 100% sensitive to Tigecycline and Colistin only. Followed by Imipenem

89.6%, and Meropenem 89.6%, followed by Amikacin 79.3%, Piperacillin/ Tazobactam 68.9%, Levofloxacin 41.3%, Ciprofloxacin 34.4% (table-2.)

Only two isolates of *Citrobacter* were found which were 100% sensitive towards Amikacin, Piperacillin/Tazobactam, Imipenem, Tigecycline, Colistin, Meropenem.

In case of Gram positive bacteria all 12 (3.28%) COPS were 100% sensitive towards Vancomycin and Linezolid, followed by Gentamicin 78%, Fluoroquinolones as 41.6%, followed by Amoxicillin/Clavulanic acid and Ampicillin / Sulbactam and Cotrimoxazole 33.3%,each , other cephalosporins , (Cefuroxime, ceftizoxime, ceftriaxone, cefixime and cefoxitin) as 25% sensitive only.(Table-3)

CONS isolates were 100% sensitive towards Vancomycin and Linezolid, followed by Gentamicin 77.7%, Levofloxacin 55.5% Cotrimoxazole 33.3%) followed by other cephalosporins and Ciprofloxacin as 22.2% sensitive. (Table-3)

Enterococci show 100% sensitivity towards Vancomycin, Amoxicillin/ C.A, Ampicillin/ Sulbactam and linezolid and Gentamicin.

Table- 2 Antibiotic Sensitivity pattern of Gram-negative Clinical isolates

Organism/Antibiotics	Klebsiella sp n = 68	Acinetobacter sp n = 163	Pseudomonas sp n = 41	Escherichia Coli n = 29	Citrobacter n = 2
Amikacin	24(35.29%)	60(36.80%)	28(68.2%)	23(79.3%)	2(100%)
Piperacillin/Tazobactam	13(19.11%)	42(25.7%)	28(68.2%)	20(68.(%)	2(100%)
Ciprofloxacin	11(16.17%)	41(25.15%)	20(48.7%)	10(34.4%)	0
Levofloxacin	16(23.5%)	50(30.6%)	23(56.09%)	12(41.3%)	0
Imipenem	59(86.76%)	150(92.02%)	41(100%)	26(89.6%)	2(100%)
Tigecycline	68(100%)	160(98.15%)	41(100%)	29(100%)	2(100%)
Colistin	68(100%)	158(96.9%)	41(100%)	29(100%)	2(100%)
Meropenem	60(88.2%)	154(94.4%)	41(100%)	26(89.6%)	2(100%)
Ceftazidime/Clavulanic acid	5(7.3%)	0	18(43.9%)	9(31.03%)	0
Cefotaxime/Sulbactam	5(7.3%)	0	18(43.9%)	9(31.03%)	0
Cefepime	5(7.3%)	0	18(43.9%)	9(31.03%)	0
Ceftriaxone	5(7.3%)	0	18(43.9%)	7(24.13%)	0
Polymixin-B	ND	ND	41(100%)	ND	ND
Ampicillin/ Sulbactam	ND	ND	ND	11(37.9%)	ND

DISCUSSION

To prevent or combat respiratory failure, life- saving procedures are done on emerging or elective basis such as endotracheal intubation and mechanical ventilation. Many clinical conditions warrant need for ventilated support like life threatening infections, sepsis in acute respiratory distress syndrome, neurological dysfunction due to poisoning drug toxicity, cerebrovascular accidents, traumas and others. Mechanical Ventilation helps to prevent deaths due to respiratory failure but on the other hand it possess great threat, by host immune response and infectious organisms that lead to life threatening lung infection.[5] Mechanically ventilated and tracheotraumatized patients are colonized with bacteria of either endogenous or exogenous origin which might end up in Vat or VAP.[6] Healthcare associated infections continue to be a major cause of patient morbidity and mortality in ICUs.

The various organisms were isolated and cultured from these samples and their susceptibility testing was done according to clinical and Laboratory standard Institute guidelines (CLSI)[4] with the intention of assessing the discriminative prevalence of various common bacteria and to identify the local prevalent antibiotic response against the detected pathogens.

Table-3 Antibiotic susceptibility pattern of Gram-positive clinical isolates

Antibiotics	COPS	CONS	Enterococci
Total Strains	n = 12	n = 9	n = 3
Gentamicin	9(78%)	7 (77.77%)	3(100%)
Cefuroxime	3(25%)	2(22.2%)	0
Ceftozoxime	3(25%)	2(22.2%)	0
Ceftriaxone	3(25%)	2(22.2%)	0
Cefixime	3(25%)	2(22.2%)	0
Vancomycin	12(100%)	9(100%)	3(100%)
Azithromycin	3(25%)	2(22.2%)	0
Amoxcillin +Calvulanic Acid	4(33.3%)	2(22.2%)	3 (100%)
Ampicillin/Sulbactam	4(33.3%)	2(22.2%)	3 (100%)
Ciprofloxacin	5(41.6%)	2(22.2%)	0
Levofloxacin	5(41.6%)	5(55.5%)	0
Cotrimoxazole	4(33.3%)	3(33.3%)	0
Linezolid	12(100%)	9(100%)	3(100%)
Cefoxitin	3(25%)	2(22.2%)	0
Penicillin	2(22.2%)	5(55.5%)	0

Our study showed 80% growth from endotracheal aspirates which are concurrent with the study of Bhaskar Thakuria et al[7]. who has reported 85% growth and V.R. Rathod et al[8] who also has also reported 85% of endotracheal aspirate growth. Another study of Santosh Khanal et al[9] Ada Siler Junior et al.[10] and Koirala et al[11]have variable growth rate of (78-92%). Another Study by Kartik S.L. et. al.[12] gave a lower growth rate of 70.07%.

As far as the bacterial profile is concerned out of 365 isolates, 303 (83.47%) were gram negative bacterial isolates (GNB) and only 22 (6.06%) were GPC, similar findings has been quoted by V.S. Rathod et al[8] in which 80% were GNB, 20% were GPC. Our study correlates with many studies and particularly as shown in one systemic review article by Yaseena Arabi et al[13] were GNB range from 41 to 92%, GPC between 6-58%. In our study 38 (10.41%) isolates were fungus whose DST was not followed as our aim of study was to chart out antibiotic susceptibility profile of the bacterial isolates only.

In our study bacterial isolates identified are *Acinetobacter sp.* 44.65%, *Klebsiella sp* 18.63%, *Pseudomonas sp.* 11.23%, *Escherichia Coli* 7.94%, *Citrobacter* 0.54%,. Similar findings were reported by Priya Santharam et. al.[14] Acinetobacter followed *Pseudomonas, klebsiella pneumonia*. Non fermenter gram negative bacilli, Escherichia Coli and then *Citrbacter*. Our study also coincides with study conducted by N. Shanmuga vadivoo et. al.[15] that *Acinetobacter* has over taken the pathogenic role in ventilated patients.

V.S. rathod et al[8] quoted *Klebsiella pneumonia* as the most common isolate followed by *pseudomonas aeriginosa* and *Acinetocabter baumannii*, in his study which coincides with vadivoo et al[15] which reported *Klebsiella* followed by *Acinetobacter* and *Pseudomonas*. Also, Shilpi Dhakar et. al.[16] detected *Klebsiella* as most common pathogen followed by *Pseudomonas, staphylococcus*, *Acinetobacter* and *Escherichia Coli* with small number of *enterobacter*, and *streptococcus.* Such contrast can be due to discriminative prevalence due to the change in the demographic region of all studies conducted.

Among GPC, in our study 3.28% were COPS, 2.46% CONS and 0.821% were Enterococci isolates which is in similarity to the findings of V.S. Rathod et al [8] were GPC contributed to 6% among micro-organisms isolates. Priya Santharam et al[14] figured out 8% *Staphylococcus aureus* and were as Dipti Chandra et. al.[17] also reported 8.82% of *Staphylococcus aureus.*

In our study *Acinetobacter* was found to be the most predominant bacteria which shows high resistance towards penicillin, cephalosporins (ceftazidime and cefepime), intermediate sensitivity for aminoglycoside (Amikacin as 36.80%) followed by fluoroquinolones (Ciprofloxacin and Levofloxacin). *Acinetobacter sp* were highly sensitive towards carbapenems (Imipenem 92.02%, Meropenem 94.4%) followed by Colistin 96.9% and Tigecycline 98.15%. 40 (24.53%) strains of *Acinetobacter sp* was multidrug resistant.

Sensitivity pattern of *Klebsiella sp.* shows high resistance towards cephalosporins. Intermediate sensitivity towards Amikacin 35.29%, 23.5% for levofloxacin and 16.17% for Ciprofloxacin. Carbapenems shows 88.2% sensitivity. Most sensitive drugs against *Klebsiella sp* were Tigecycline and Colistin as 100% each. 44(64.70%) strains of *Klebsiella sp* were multi drug resistant[18]

In our study *Pseudomonas sp* shows high sensitivity pattern towards Tigecycline 100%, Colistin 100%, Meropenem 100%, Imipenem 100%, Polymixin B 100%, followed by Amikacin 68.2%, and combination Piperacillin/ Tazobactam 68.2%. Cephalosporins gave 43.9% sensitivity for pseudomonas. Flouroquinolones were also intermediate sensitive for Pseudomonas (Levofloxacin 56.09% and Ciprofloxacin 48.70 %.)

Tigecycline and Colistin were 100% sensitive for *Eschericha Coli* followed by Carbapenems (Imipenem and Meropenem 89.6% each). Amikacin has also significant sensitivity pattern for *Escherichia Coli* 79.3% followed by combination of Piperacillin/Tazobactam. Levofloxacin has lesser senstivity 41.3% and Ciprofloxacin 34.4%. All specimens show a great resistance towards cephalosporins with a sensitivity pattern of 24.13%.

Few species of *Citrobacter* were isolated which were highly sensitive towards Amikacin, Piperacillin /Tazobactam, Imipenem, Meropenem, Colistin, Tigecycline as 100% sensitive. But all were resistant towards flouroquinolones and cephalosporins.

In case of *COPS, CONS* and *Enterococci* all isolates were found 100% sensitive towards Vancomycin and Linizolid followed by Gentamicin,(78%) Flouroquinolones 41.6%, combination of Amoxicillin/C.A 33.3% /22.2% respectively and Ampicillin /Sulbactam 33.2%/ 22.2% respectively. 9 (75%) strains were identified as Methicillin resistant *Staphylococcus aureus*. Gram positive organisms of E.T. aspirates in our ICU set up were mostly resistant to penicillin derivatives and cephalosporins.

CONCLUSION

The study reveals that the antibiotic susceptibility pattern varies across region and timeline and hence studies examining the local susceptibility pattern should be carried out at every centre. Endotracheal Intubation is a major risk factor in causing iatrogenic infections to patient which leads to an increase in the morbidity and mortality. Our study reported a high percentage resistance among gram negative bacilli to cephalosporins. Aminoglycosides (Amikacin), and a combination of Piperacillin/Tazobactam were found to be moderately effective. Carbapenems, Colistin and Tigecycline were found to be most effective drug of choice.

For gram positive bacterial isolates shows significantly high resistance for penicillin and cephalosporin. 75% MRSA strains were also indentified. Vancomycin and linezolid were found to be most sensitive followed by Aminoglycoside (Gentamicin).

From present study we have concluded that analyzing the E.T aspirate was important as the sensitivity to the antibiotic obtained, is an alarming factor for efficacious and judicious use for antibiotics. This study will help us in implementing different antibiotics prophylactically with regard to the commonly obtained sensitivity pattern.
