ABSTRACT: Chronic abdominal pain is a FREQUENTLY ENCOUNTERED problem and abdominal tuberculosis is a very common cause of the same. Diagnostic laparoscopy is a highly sensitive, specific, and safe procedure for the early diagnosis of abdominal tuberculosis. The procedure is beneficial because it is minimally invasive and provides diagnostic benefit in terms of both visual appearances and tissue yield for histopathological and cytological confirmation. We have performed an extensive retrospective study with 250 subjects and were able to justify the safety, sensitivity & early selection of laparoscopy as a procedure of choice to confirm tuberculosis in chronic abdominal pain.

INTRODUCTION: Chronic abdominal pain is a very frequent problem putting a heavy burden on the limited health resources in a developing country like India. Often the clinical presentation is vague and nonspecific and the available diagnostic modalities fail to pinpoint the underlying pathology.

Histopathological confirmation of abdominal Tuberculosis is difficult due to suboptimal noninvasive access to the pathology.

Tuberculosis (TB) remains a major global health problem. It causes ill-health among millions of people each year and ranks as the second leading cause of death from an infectious disease worldwide, after the human immunodeficiency virus (HIV).The latest estimates report that there were almost 9 million new cases in 2011 and 1.4 million TB deaths (990 000 among HIV negative people and 430 000 HIV-associated TB deaths). [1]

AIMS AND OBJECTIVES: To evaluate the role of laparoscopy as a confirmatory diagnostic tool in diagnosing abdominal Tuberculosis as a leading cause of chronic abdominal pain.

MATERIAL AND METHODS: We performed a retrospective evaluation of patients presented for evaluation of chronic abdominal pain over the last three years in SAIMS medical college and hospital, Indore.

The duration of the study was 3 years and the total study subjects were 250.

Patients presenting with vague abdominal pain and other gastrointestinal complaints of three months or more duration with no conclusive diagnosis despite many investigations were included.

Follow up study of these patients were performed on basis of available contact details and data stored in the medical record department & out patient department.

Out of all the laparoscopies conducted in 212 patients, 9 were converted into formal laparotomies because of intraoperative problems like difficult access, dense adhesions, and poor visualization. so the identification of anatomical details of intraabdominal structures was not possible. These 9 cases were converted to laparotomies for diagnostic purposes only. and in these 9 conversion, after opening the abdomen by laparotomy, the intraabdominal contents were explored, the visual findings were noted and the biopsies were taken from representative tissues and the biopsy specimens were sent for histopathology.

Histopathological report of biopsy established the diagnosis of abdominal tuberculosis in 123 patients (58%). All patients were started on antitubercular therapy and they showed good

Clinical response-

Diagnosis	Percentage
Tuberculosis	58%
Malignancy	11%
Post operative adhesions	8%
Pelvic inflammatory disease	7%
Recurrent appendicitis	6%
Ovarian cyst, fimbrial cyst	3%
Cirrhosis liver	2%
Others	5%

The prominent laparoscopic findings noted were the following,

MALIGNANCY
Intestinal mass lesions
Omental mass
Diffuse carcinomatosis
Malignant ascites
abdominal lymphadenopathy

PELVIC INFLAMMATORY DISEASE
Fluid in pouch of Douglas
Adnexal pathology

Abdominal tuberculosis	
Stalactic bands	
Multiple white tubercles /nodules	DSC00022.JPG
Omental thickening	DSC00017.JPG
Hyperemic edematous bowel	
Dense inter bowel loop adhesions	
Mesenteric lymphadenopathy	
Straw colored ascites	

High correlation with Bhargava et al [3]

Post operative adhesions

Earlier Laparotomy was the only definitive diagnostic approach. Though it yields correct diagnosis but at the cost of significant morbidity. Laparoscopy provides minimally invasive access to the peritoneum, thus reducing morbidity without compromising the diagnostic yield.
During laparoscopy , abdominal tuberculosis is suggested by macroscopic signs like tubercles/nodules over the peritoneal surfaces, thickening and hyperemia of omentum, inflammatory adhesions and a long fibrous band extending from the parietal to visceral peritoneum called *'Stalactic band'* which is quite characteristic of abdominal tuberculosis.[8]
Analysis of macroscopic findings during laparoscopy in 123 histopathological confirmed cases of abdominal tuberculosis.

In our study, small white tubercles over peritoneal surfaces were found in 106 patients (86%)
Omental thickening was found in 101 patients (82%).

Stalactic band which is the best macroscopic confirmatory feature was found in 110 cases [89%].

There were no complications or mortality in any of the laparoscopic surgery.

In 9 cases intraoperative decision for conversion of Laparotomy was taken due to difficult access, dense adhesions, inadequate exposure and poor identification of anatomical details.

The biopsy tissues obtained during laparoscopy were sent for histopathological examination.

In all the patients in whom histopathological confirmation of abdominal tuberculosis was obtained, antitubercular treatment was started promptly and the patients improved symptomatically very soon.
Several authors confirm the role of laparoscopy in diagnosing abdominal tuberculosis,

Author	Study Subjects	Sensitivity
Bhargava et al [3]	87	95%
Rai & Thomas et al [4]	36	100%
Ibrahullah et al [5]	23	87%
Razi hospital , Iran [6]	29	98%
Our Study ,SAIMS	212	58%

The beneficial aspects of diagnostic laparoscopy were

Author	Benefits
Bhargava et al [3]	Visual appearance super cede histology & culture for diagnosing tuberculosis
Rai & Thomas et al [4]	Early laparoscopy is beneficial for earlier diagnosis
Ibrahullah et al [5]	Laparoscopy is a safe and mortality free procedure
Razi hospital , Iran [6]	High sensitivity
Rajiv Jain et al, SAIMS	Early laparoscopy is the investigation of choice for abdominal Tuberculosis

Thus laparoscopy with tissue biopsy is the most sensitive and specific diagnostic procedure for abdominal tuberculosis and can be termed as the investigation of choice.

ABSTRACT

Background: Acute Abdomen is a term used to encompass a spectrum of surgical, medical and gynecological conditions ranging from trivial to life threatening conditions, which require hospital admission, investigations and treatment. The purpose of this study was to identify the epidemiological pattern and to determine the spectrum of disease causing "non-traumatic acute abdomen in central India".
Methods: This is a prospective study of 98 patients of non-traumatic acute abdominal cases conducted in the Department of Surgery, Sri Aurobindo Medical College and PG Institute, Indore, Madhya Pradesh, India. In this study, preoperative detailed history and thorough physical examination was done for all acute abdominal emergencies, to arrive at pre-operative diagnosis.
Results: Amongst the study of 98 patients, males have higher incidence of acute abdomen with the young age group (21-30 years) most commonly affected. Perforation peritonitis constituted the most common cause of acute abdomen (39.7%), followed by acute appendicitis (37.7%), followed by intestinal obstruction (14.2%).
Conclusions: This study was conducted to evaluate the epidemiology, etiology and differential diagnosis of non-traumatic acute abdomen. At the end of the study, we had a better insight of the spectrum of the condition and we concluded that there is more scope for further work in the same field for better understanding of this topic.

Keywords: Acute Abdomen, Appendicitis, Perforation peritonitis

INTRODUCTION

Acute Abdomen is a term used to encompass a spectrum of surgical, medical and gynecological conditions ranging from trivial to life threatening conditions, which require hospital admission, investigations and treatment.[1] The term encompasses long list of differential diagnosis which may vary from self-limiting to life threatening conditions. Abdominal pain is one of the common reasons for visits to the emergency room. Although for the majority of patients, symptoms are benign and self-limited, a subset will be diagnosed with "acute abdomen", as a result of serious intra-abdominal pathology necessitating emergency intervention.[2] The most appropriate therapy should be initiated with the patient's clinical status optimized. The workup should first include a thorough but efficient acquisition of the patient's history and physical examination followed by judicious use of laboratory and radiologic studies.

The most common symptoms are abdominal pain and vomiting whereas tenderness and guarding were the most frequent clinical signs. Specifically, gastroenteritis, acute appendicitis and abdominal trauma are commonest causes of acute abdomen in children and young adults, whereas biliary disease, intestinal obstruction, diverticulitis and

such cases and will also help in establishment of prompt treatment guidelines of such patients.

ABSTRACT

BACKGROUND
Acute abdominal pain is a common complaint of patients presenting at the Emergency Department. Patients presenting with acute abdominal condition which often requires an immediate surgical intervention and is one of the commonly encountered emergencies in the practice of General Surgery. Very often an accurate diagnosis cannot be made without surgery and many wonders are revealed on opening the abdomen. So it is often the last court of appeal in investigating abdominal cases.

MATERIALS AND METHODS
This is a prospective study of 98 patients of non-traumatic acute abdominal cases conducted in a Tertiary Care Hospital of Central India. In our study, all routine blood investigations were carried out and relevant radiological investigations like abdomen x-ray, ultrasound whole abdomen was done in majority of patients and CT scan was done wherever needed. In our study 97 patients were managed surgically, while conservative management is done in only 1 patient.

RESULTS
Amongst the study of 98 patients x-ray, USG and CT were used as diagnostic modalities. Maximum cases were operated, while conservative management was done in one patient.

CONCLUSION
Our study is a sincere attempt to know the sensitivity of diagnostic modalities and to evaluate the treatment protocol in non-traumatic acute abdomen cases.

KEYWORDS
Acute Abdomen, Laparotomy, Abdomen X-Ray, Ultrasound Abdomen.

HOW TO CITE THIS ARTICLE: Jain R, Gupta V. A prospective study of various available diagnostic and treatment modalities and intraoperative findings of non-traumatic acute abdominal cases in a tertiary care hospital of Central India. J. Evolution Med. Dent. Sci. 2016;5(92):6829-6834, DOI: 10.14260/Jemds/2016/1545

BACKGROUND

Acute abdominal pain is a common complaint of patients presenting at the Emergency Department.[1] Approximately, 10% of presentations at the Emergency Department are because of acute abdominal pain.[2] It can be caused by a variety of diseases ranging from mild and self-limiting to life-threatening diseases.[3] An early and accurate diagnosis results in more appropriate management and subsequently leads to better outcomes. The first step in the diagnostic pathway is clinical evaluation. In daily practice, a preliminary diagnosis should be made based on medical history, physical examination and in some cases laboratory parameters. After clinical assessment, the decision can be made to perform additional diagnostic investigations to increase certainty of the diagnosis. The use of additional imaging modalities such as plain radiography, ultrasound and Computed Tomography (CT) has increased over the years. Only a few decades ago, when imaging was not widely available and its diagnostic accuracy was low, patients would immediately proceed to the operating theatre. However, many causes can be treated conservatively and do not need diagnostic laparoscopy and laparotomy.[3]

The terms "acute abdomen" and "abdominal emergency," which are constantly applied to such cases signify the need for prompt diagnosis and early treatment. Patients presenting with acute abdominal condition, which often requires an immediate surgical intervention and is one of the commonly encountered emergencies in the practice of General Surgery.[4,5] Very often an accurate diagnosis cannot be made without surgery and many wonders are revealed on opening the abdomen. So it is often the last court of appeal in investigating abdominal cases.[6] The "aim of this study" was to study various diagnostic modalities, their effectiveness and treatment modalities in patients presenting with "Non-Traumatic Acute Abdomen in Central India."

MATERIALS AND METHODS

This is a prospective study of 98 patients of non-traumatic acute abdominal cases conducted in a Tertiary Care Hospital of Central India. In our study, all routine blood investigations were carried out and relevant radiological investigations like abdomen x-ray, ultrasound whole abdomen was done in majority of patients and CT scan was done wherever needed.

The Sensitivity, Specificity, Positive Predictive Value and Negative Predictive Value of Computerised Tomography Scan is given below

Sensitivity:	81.81%
Specificity:	25%
Positive Predictive Value:	60.0%
Negative Predictive Value:	50.0%

(N = 98)

Type of Management	No.	%
Open surgery	88	92.6
Laparoscopic surgery	09	9.2
Conservative	01	1.0
Total	98	100.0

Table 5. Distribution of Patients according to Type of Management

As per above table out of 98 patients open surgical management was done in 88 (92.6%), while laparoscopic surgery was done in 9 (9.2%) and conservative management was done in only 1 (1.0%) of the total patients studied.

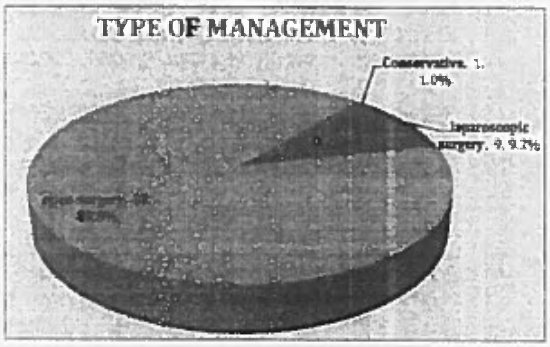

Figure 2. Pie Diagram showing Type of Management [Ref. Table No. 5]

(N = 39)

Site of Perforation	No.	%
Ileal	18	46.2
Gastric	14	35.9
Appendicular	2	5.1
Jejunal	2	5.1
Caecal	2	5.1
Sigmoid	1	2.6
Total	39	100.0

Table 6. Distribution of Cases of Perforation Peritonitis on the Basis of Site of Perforation

In our study, perforation peritonitis was seen in 39 patients. Of these 39 patients, perforation which formed the major cause of acute abdomen in the study was found to be ileal in 18 (46.2%) followed by gastric in 14 (35.9%).

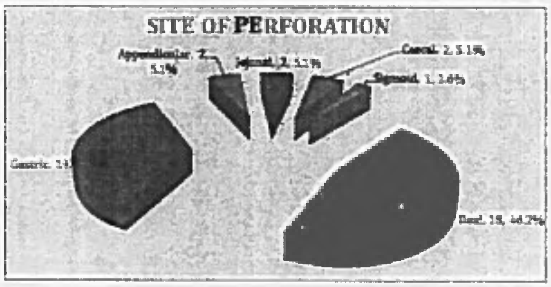

Figure 3. Pie Diagram showing Sites of Perforation [Ref. Table No. 6]

(N = 3)

Ruptured Liver Abscess	No.	%
Surgical	2	66.7
Laparoscopic drainage	1	33.3
Total	3	100.0

Table 7. Treatment of Ruptured Liver Abscess

There were 3 cases of ruptured liver abscess. Of these 2 (66.7%) were managed surgically, while laparoscopic drainage was done in 1 (33.3%) of the total patients studied.

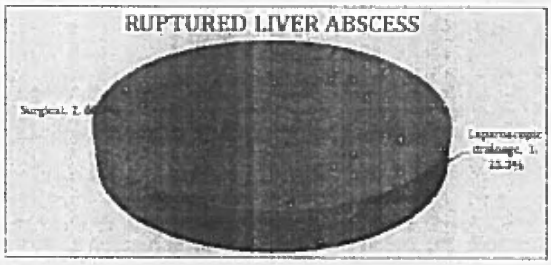

Figure 4. Pie Diagram showing Management of Ruptured Liver Abscess [Ref. Table No. 7]

(N = 13)

Aetiology	No.	%
Adhesions/bands	9	69.2
Volvulus	2	15.4
Foreign body	1	7.7
Internal hernias	1	7.7
Total	13	100.0

Table 8. Aetiology of Cases of Intestinal Obstruction

Intestinal obstruction was seen in 13 cases in our series. Of these, most common aetiology was found to be adhesions/bands in 9 (69.2%) followed by volvulus in 2 (one caecal and one sigmoid) (15.4%), foreign body and internal hernias in only 1 (7.7%) of the total patients studied.

role in making decision regarding surgery[7] and to know various treatment modalities in patients presenting with non-traumatic acute abdomen in a tertiary care hospital of Central India.

Investigations

In our study, abdomen x-ray is the investigation with highest sensitivity (95.2%) followed by ultrasound abdomen (93.65%). In a similar study done by K. Gupta et al[8] in 2005, where ultrasound is the investigation of choice with highest sensitivity (98.3%) followed by abdomen x-ray (70.9%). Hence, results in our study are different with the findings of the study done by K. Gupta et al.

Type of Management

In the present study, majority of patients were treated by open surgical method (92.6%) and some patients by laparoscopic surgery (9.2%). In a similar study done by Ferdinando Agresta et al[9] in 2004 where majority of patients were treated by laparoscopic surgery (94.1%), while less by open surgical method (5.8%). Hence, results in our study regarding type of management are different from the study done by the author.

Site of Perforation

In our study, the most commonest site of perforation peritonitis is ileal (46.2%) followed by gastric (35.9%). In a similar study done by Rajender Singh Jhobta et al[10] in 2006, where the most commonest site was duodenal (57%) followed by ileal (15%) and study done by Memon et al[11] in 2008, the commonest site was gastric (14.6%) followed by ileal (5.9%). Hence, findings in our study regarding site of perforation is different as compared with the findings of other authors.

Treatment of Ruptured Liver Abscess

In our study, majority of patients of ruptured liver abscess were treated by open surgical method (66.7%). In a similar study done by Jin Fu Tu et al[12] in 2011, majority of patients of ruptured liver abscess were treated by open surgical method (58.06%). Hence, findings in our study is similar to findings of Jin Fu Tu et al.

Aetiology and Management of Intestinal Obstruction

In our study, the common cause of intestinal obstruction is adhesions/bands (69.2%) followed by volvulus (15.4%). In a similar study done by Patrick G. Jackson et al[13] in 2011, the common cause is adhesions/bands (60%) followed by neoplasm (20%). Hence, our study on aetiology of intestinal obstruction matches with the study done by the author.

In our study, majority of cases of intestinal obstruction were managed by open surgical method (85.7%) and few cases by laparoscopic surgical management (7.1%) and remaining by conservative management (7.1%). In a similar study done by Adhikari Souvik et al[14] in 2010, majority of cases were managed by open surgical method (78.4%), while conservative management was done (14.17%) and in a similar study done by Mohamed AY et al[15] in 1997 majority of patients were managed by open surgical method (73%) and conservative management (27%). So our findings match with the findings of other studies and the standard treatment of acute intestinal obstruction is by surgery only.

Patients Treated by Laparoscopy

In present study out of nine patients in which laparoscopic surgery was done for management in majority of patients laparoscopic appendicectomy was done (33.3%) for acute appendicitis, diagnostic laparoscopy with appendicectomy (22.2%), laparoscopic cholecystectomy (22.2%) for gall bladder pathology, while laparoscopic adhesiolysis (11.1%) of intestinal obstruction. In a similar study done by Edvaldo Fahel et al[16] in 1999, where laparoscopic appendicectomy (44.15%) was done for acute appendicitis followed by laparoscopic cholecystectomy (21.4%) for gall bladder pathology. Thus, we conclude that in an era of laparoscopic surgery, it has been the "gold standard" for many elective procedures and has been used in abdominal emergencies for diagnosis as well as for treatment purposes. Different positions of appendix found during appendicectomy in the present study, the commonest position of appendix found during appendicectomy is retrocaecal (81.1%) followed by pelvic (10.1%). In a similar study done by Patel KG et al,[17] in 2013 the commonest position of appendix found during appendicectomy is retrocaecal (62%) followed by pelvic (13%). Hence, our study on different positions of appendix found during appendicectomy matches with the study done by author.

CONCLUSION

The increasing incidence of cases of non-traumatic acute abdomen is a diagnostic dilemma for the surgeons and warrants early recognition and prompt treatment to avoid major morbidity and mortality. Acute abdomen is often a surgical emergency and a challenge to any surgeon. Abdominal pain is a common presenting complaint in the emergency department and surgeons must consider multiple diagnoses, especially in those cases that require immediate intervention in order to limit morbidity and mortality. Rigorous approach to diagnosis is mandatory. It is extremely important for surgeons to develop the skill of identifying patients with an "acute abdomen" requiring immediate surgical intervention. Our study is a sincere attempt to know the sensitivity of diagnostic modalities, treatment protocol in non-traumatic acute abdomen cases presenting in tertiary care centre in Central India.

ABSTRACT: The diagnosis of cervical tuberculous lymphadenitis has been performed by histological examination using excisional biopsy specimens. However a non-invasive diagnostic procedure alternative to invasive excisional biopsy has been required and fine needle aspiration cytology as well the polymerase chain reaction (PCR) techniques have become useful modalities. The aim of this study was to evaluate and compare different diagnostic modalities and establish their effectiveness in current conditions. We performed a retrospective study of two hundred patients of tuberculous cervical lymphadenitis admitted in the department of surgery, SAIMS Medical college and PG institute in a two year period from January 2011 to December 2012. Excision biopsy specimens and needle aspiration specimens were collected from all patients who were suspected as having cervical tuberculous lymphadenitis on the basis of clinical features, Mantoux test and other diagnostic techniques. The histopathological positive rates, the time period necessary for diagnosis, the rupture rate of the local skin lesion and the detection ratio of mycobacterium were compared between the two percutaneous approaches. The diagnosis of tuberculous lymphadenitis was successful in all cases either by cytological examination or with the histological approach. The sensitivity and the diagnostic efficacy of FNAC in detecting tubercular lymphadenitis were 87% and 80% respectively. The rupture rate of the local skin after the excisional biopsy was higher than that of the needle aspiration procedure . The time required for diagnosis was significantly longer than that of the needle aspiration procedure . Fine needle aspiration cytology is highly recommended as a less invasive method of diagnosis of cervical tuberculous lymphadenitis, but excision biopsy and histological examination is the gold standard.

INTRODUCTION: Cervical lymphadenitis is the most common head and neck manifestation of tubercular infections. The incidence of tubercular cervical lymphadenitis has increased either as a manifestation of a systemic tuberculous disease or a unique clinical entity localized to neck. It remains a diagnostic and therapeutic challenge because it mimics other pathologic processes and yields inconsistent physical and laboratory findings.

A high index of suspicion is needed for the diagnosis of tubercular cervical lymphadenitis. A unilateral single or multiple painless lump, mostly located in posterior cervical or supraclavicular region can occur. A thorough history and physical examination, tuberculin test, staining for acid-fast bacilli, radiologic examination, fine-needle aspiration and PCR will be very helpful in arriving at an early diagnosis and institution of treatment before a final diagnosis can be made by biopsy and culture. Tubercular lymphadenitis is best treated as a systemic

negative predictive value	0.87	87.9
diagnostic efficacy	0.88	88.5

lymphadenopathy. We took the results confirmed by biopsy and histopathology as standard against which the results obtained by FNAC were compared. We found the sensitivity of FNAC in diagnosing Tubercular cervical lymphadenitis was 87% and specificity was 54%.
Manitchotpisit et al had shown sensitivity and specificity of 48% and 87.5% respectively in the diagnosis of cervical tuberculosis on FNAC.[9]

Many studies have found FNAC as an highly sensitive and specific tool for the diagnosis of metastatic malignancies.

In our study 17 cases were diagnosed as having metastatic carcinoma on FNAC. 22 cases of metastatic carcinoma were missed on FNAC which were picked by histopathology.

Thus sensitivity and specificity of FNAC in detecting malignant lymph node was 42% and 99% respectively.

This was in sharp contrast to a similar study done by Shahzad Et al who found sensitivity to be 95% with 100% positive predictive value.[10]

Squamous cell carcinoma is the commonest malignancy presenting in the cervical lymph nodes, metastasizing from upper aero digestive tract a fact validated in our study.

Thus in our study we found that the sensitivity and the diagnostic efficacy of FNAC is very high in diagnosing tubercular cervical lymphadenitis. Though in our study the sensitivity of FNAC in diagnosing metastatic lymphadenopathy was low but the specificity was very high [99%].so our study clearly highlights the diagnostic importance of FNAC in patients of cervical lymphadenopathy.

The relative sensitivities of different procedures and the potential therapeutic benefits should be considered in making the choice of diagnostic approach. Excisional biopsy is the most invasive approach to diagnosis; however, it has the highest sensitivity and may produce a more rapid and favorable symptomatic response [11] and has been recommended in cases involving multiple nodes [12]. Rare complications of biopsy include the rupture of the local skin lesion, postsurgical pain, wound infection, sinus formation, non healing ulcer and scar [13]. In a study from Hong Kong, 80% of specimens from excision biopsy yielded positive culture results, compared with 17% from fine-needle aspiration (FNA) specimens [14].

CONCLUSION: Histopathology is most rewarding for diagnosis of cervical lymphadenitis, its Feasibility is limited due to lack of facilities and non-acceptability, being an invasive procedure. Previously, biopsy was used for diagnosis of tubercular lymphadenitis; now FNAC is greatly replacing it because of it being a noninvasive, simple and cost effective procedure which can easily be done in office or outpatient sitting.

A STUDY OF ABDOMINAL GOSSYPIBOMA

Rajiv Jain[1], Mohan Gadodia[2]

[1]Associate Professor, Department of General Surgery, Sri Aurobindo Medical College & Post Graduate Institute.
[2]Resident, Department of General Surgery, Sri Aurobindo Medical College & Post Graduate Institute.

ABSTRACT

BACKGROUND

Gossypiboma or textiloma is a term specifically coined to describe a retained surgical sponge in the body after a surgical procedure. Any foreign body accidentally left in the abdomen often requires reoperation for its removal which increases the morbidity of the patient, cost of treatment and medico legal problems. The aim of this research is to study the incidence, presenting features, management and outcome of Abdominal Gossypiboma. Design: Retrospective study. Setting & Duration: Department of Surgery, Sri Aurobindo Medical College & PG Institute, Indore, from 2005 to 2015. Patients: Patients presenting with a history of previous surgery, signs of an abdominal lump or acute abdomen, which turned out to be a Gossypiboma either in radiological investigations or during surgery were included in the study.

METHODOLOGY

The data of patients who underwent Laparotomy in last 10 years was collected from Medical Records Department and the cases of Abdominal Gossypiboma were selected. All the patients were clinically evaluated and radiological examinations of patients were done to confirm diagnosis. Every patient was optimized and subjected to Laparotomy.

RESULTS

A total of 6889 laparotomy operations were performed during this period, which translate incidence of Abdominal Gossypiboma to be one in 574 operations. A total number of 12 patients of Gossypibomas were studied, which presented with signs and symptoms of an abdominal mass with or without signs of acute abdomen. X-ray findings were foreign body with whorl appearance and gas bubbles. Ultrasound revealed hypo-echoic densities with encapsulation. Exploratory laparotomy was done in all the 12 cases.

CONCLUSION

Gossypiboma is rare but serious complication of any surgical procedure and hence every possible measure should be taken to prevent its occurrence. We recommend the adoption of a very systematic swab and instrument counting policy to prevent this complication.

KEYWORDS

Retained Sponge, Gossypiboma, Medico-legal.

HOW TO CITE THIS ARTICLE: Jain R, Gadodia M. A study of abdominal gossypiboma. J. Evolution Med. Dent. Sci. 2016;5(44): 2825-2830, DOI: 10.14260/jemds/2016/637

INTRODUCTION

Gossypiboma, is a term derived from the combination of Latin words "Gossypium" meaning cotton and Swahili word "Boma," which means place of concealment. It is a mass within the body consisting of a surgical sponge (Cotton matrix) surrounded by an inflammatory reaction. Surgical sponge left involuntarily inside a body cavity is a serious, but avoidable complication.

In the abdomen the surgical sponge or any foreign body can be surrounded by omentum and intestines, which attempt to encapsulate it in order to localize any foreign body reaction, but in the process various grievous complications can take place.

The pressure and irritation on the intestines can hamper the blood supply and lead to gangrene of the bowel loops with the sponge eroding through its walls into the lumen. This can lead to intestinal obstruction, fistula formation or gangrenous bowel.

The reported incidence of gossypiboma is one in 100-5000 operations. Occurrence of this complication is very rare in western countries due to their strict adherence to operation theatre policies.

METHODOLOGY

We searched the medical records of all the patients who had undergone Laparotomy surgery during the study period of 10 years, i.e. from 2005 to 2015. We found a total of 12 confirmed cases of Abdominal Gossypiboma [Retained Surgical Sponge] after going through the medical records. All of these patients were treated in Department of Surgery, Sri Aurobindo Medical College and PG Institute during this period.

This medical college is a tertiary care centre of central India, catering to a large number of population from Madhya Pradesh state and the surrounding states. Relevant data about these 12 patients was retrieved from the Medical Records Department. The collected data was analysed and recorded in the parameters of age, sex, details of previous surgery, clinical

The investigations used for evaluation were erect abdominal radiograph, ultrasonography abdomen and CT scan of abdomen apart from routine haematological and biochemical tests.

Preoperative diagnosis of retained surgical sponge was made in 9 cases, while in 3 cases the confirmed diagnosis was possible during surgery only.

During surgery, in the cases which were diagnosed as intestinal obstruction [4 cases], the retained sponge was found between intestinal loops covered by fibrous tissues and causing dense adhesions between the bowel loops. Sharp dissection was done to separate the entangled bowel loops and the sponge was removed without damage to the adhered bowel loops.

Out of the 3 cases which were diagnosed as perforation peritonitis, in case no. 1 the retained sponge was found eroding the anterior wall of stomach. The sponge was removed and the rent in stomach was repaired in 2 layers. In case no. 2, the retained sponge folded in 2 layers was lying embedded in the transverse mesocolon and causing a large perforation on the mesenteric border of transverse colon. The sponge and involved part of mesocolon was removed and primary repair of colonic perforation was done in two layers. This patient developed a leak from the repair site in the postoperative period and subsequently burst abdomen. Relook laparotomy was done and the transverse loop colostomy was fashioned. While in Case No. 3, the sponge was forming an inseparable cocoon with loops of small bowel. Resection of involved segment of about one foot of Jejunum and end-to-end jejunojejunal anastomosis was done.

Out of the 5 patients who presented with asymptomatic lumps during surgery, the sponge was found at various places like adhered to anterior abdominal wall, uterus and adnexa, splenic fossa, etc. In Case No. 8, the sponge was found adhered to anterior abdominal wall and small bowel loops and left adnexa. While the other locations were right paracolic gutter [Case No. 9], pelvis [Case No. 10], splenic fossa [Case No. 11] and uterus and adnexa [Case No. 12]. In all cases, the sponge was removed by meticulous dissection without damage to adhered structures.

The patients who underwent planned laparotomies for asymptomatic lumps had uneventful recovery with no morbidity. Out of 4 patients of intestinal obstruction, 2 patients had prolonged ileus and 3 patients had wound related complications like seroma, pus discharge, etc. which were managed by conservative methods.

Out of the 3 patients of perforation peritonitis, all had wound related complications and 1 had burst abdomen [Case No. 2]. One patient [Case No. 2] developed a leak from repaired transverse colon perforation, which was detected on 5th POD. Relook laparotomy was done and loop transverse colostomy was fashioned. There was no mortality in our study.

Case No.	Case Diagnosis	Operation Done	Intra-Operative Findings	Post-Operative Complications
1.	Perforation Peritonitis	Exploratory Laparotomy	Sponge Causing Gastric Perforation	Wound Seroma
2.	Perforation Peritonitis	Exploratory Laparotomy	Sponge Eroding Transverse Colon	Burst Abdomen and Re-Exploration
3.	Perforation Peritonitis	Exploratory Laparotomy	Sponge Forming Inseparable Cocoon with Small Bowel Loops	Wound Pus Discharge
4.	Intestinal Obstruction	Exploratory Laparotomy	Sponge Adhered to Distal Ileum and Caecum	Prolonged Ileus
5.	Intestinal Obstruction	Exploratory Laparotomy	Sponge Adhered to Ileal Loops	Wound Seroma
6.	Intestinal Obstruction	Exploratory Laparotomy	Sponge Adhered to Jejunal Loops	Wound Pus Discharge
7.	Intestinal Obstruction	Exploratory Laparotomy	Sponge Adhered to Ileal Loops and Sigmoid Colon	Prolonged Ileus and Wound Seroma
8.	Abdominal Lump	Exploratory Laparotomy	Sponge Densely Adherent to Anterior Abdominal Wall, Small Bowel Loops & Left Adnexa	None
9.	Abdominal Lump	Exploratory Laparotomy	Sponge in Right Paracolic Gutter with Flimsy Adhesions to Small Bowel Loops	None
10.	Abdominal Lump	Exploratory Laparotomy	Sponge Lying in Pelvis and Adherent to Surrounding Structures	None
11	Abdominal Lump	Exploratory Laparotomy	Sponge in Splenic Fossa and Adherent to Parieties	None
12.	Abdominal Lump	Exploratory Laparotomy	Sponge Adhered to Uterus and Right Adnexa	None

Table 2: Table Showing Intraoperative Findings and Post-Operative Complications after Gossypiboma Surgery

DISCUSSION

Gossypiboma or retained sponge is an important topic of discussion, as it leads to significant embarrassment and can lead to humiliation and lawsuit as well. The reported incidence of gossypiboma varies in different studies and the actual number is difficult to ascertain, because of low reporting rate due to medico legal implications.[1] In world literature, various authors like Noyle,[2] Zbar,[3] and Risher,[4] have reported incidence of Gossypiboma to be one in 100 to 5000 operations. In our study, incidence was found to be 1 in 574 operations.

Fig. 6: Intraoperative Photograph showing Gossypiboma Adhered to Transverse Mesocolon and Adjacent Structures [Case 2]

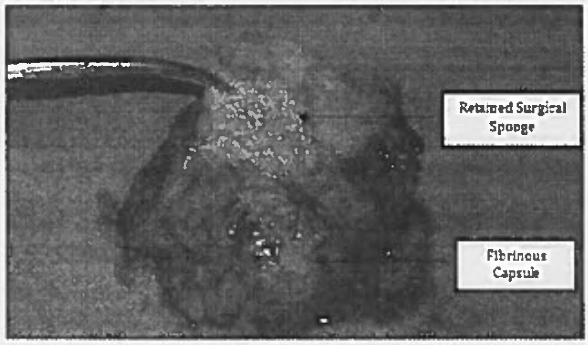

Fig. 7: Photograph of Specimen showing Retained Sponge Inside a Fibrinous Capsule [Case 10]

CONCLUSION

Gossypiboma is a rare, avoidable, but serious postoperative complication. It is usually asymptomatic and generally has nonspecific clinical findings. Hence, the diagnosis is often delayed. Abdominal Gossypiboma can cause wide variety of complications like perforation of viscera and adhesion to the adjacent structures. It can also be a cause for serious medico-legal problems. It is best to avoid gossypiboma. The surgeons should comply with the current recommendations on the prevention of retained foreign bodies including use of radiological markers and routine pre- and post-operative sponge count. Gossypiboma should be included in the differential diagnosis of soft-tissue masses or localized abdominal pains in patients with a history of prior operation.

ABSTRACT

Background: Abdominal wall hernias are most frequently encountered in surgical practice accounting for 15% - 18% of all surgical procedures. The incidence of abdominal wall hernia in different countries varies from 100 -300/100000 per year. Of which most common being the inguinal hernias and femoral hernia being the least common. Midline ventral hernias are the next common variety of abdominal wall hernia after inguinal hernia. Ours is a tertiary care hospital, medical college and PG institute in central India. Apart from routine hernias, we have managed successfully some very rare varieties and developed management protocols. Here we are providing an analysis of these unusual presentations.

Methods: This is a retrospective study in which we analyzed the data's of hernia patients presented in our institute over the period of 7 years (2008-2014). Out of 765 patients, who were diagnosed having hernia, 680 were operated in our institute. Among these cases, we have selected 12 very rare and unusual cases which stood as diagnostic and management challenge and which were operated by a single surgeon and his team.

Results: Out of the 12 cases of atypical hernias, 11 patients underwent surgical intervention. There was no mortality. 6 patients had some postoperative complications which were managed during their Hospital stay only. After discharge, all the patients were followed at regular intervals. There was no recurrence or other complication noted in 1 year follow up. Most common post-op complication was seroma which was seen in 50% of the operated patients. Other complications were wound infection (16.66%) and wound dehiscence (8.33%).

Conclusions: The infrequent encounter with the unusual varieties of Hernias can lead to the mental bias and becomes a diagnostic challenge for the general surgeon. The purpose of publication of these rare varieties is to increase our spectrum of knowledge and to provide diagnostic and therapeutic armamentarium to deal with these difficult situations.

INTRODUCTION

Hernia is derived from a Latin word meaning "a rupture". Abdominal wall hernias are most frequently encountered in surgical practice accounting for 15% - 18% of all surgical procedures.[1,2] Worldwide, more than 20 million hernias are operated per year.

The incidence of abdominal wall hernia in different countries varies from 100-300/100000 per year.[3] Of which most common being the inguinal hernias and femoral hernia being the least common. Midline ventral hernias are the next common variety of abdominal wall hernia after inguinal hernia, most common after interventions involving the lower abdomen (incisional hernia). According to their locations, these are further

The following cases and their management have been discussed in detail.

In both the cases of SPC site Hernia, previous SPC tract and hernia sac were isolated and excised, a new SPC tract was created 5 cm below and lateral to old site, hernia defect was closed, anterior rectus sheath was reconstructed and wide synthetic polypropylene mesh was placed.

Inonecase of Femoral hernia, the clinical and radiological diagnosis was inguinal hernia and the correct diagnosis of femoral hernia was established intraoperatively only. In the remaining 2 cases, femoral hernia was diagnosed through clinical and radiological methods. Lotheissen repair was done in all cases.

Two cases of inguinal hernia with fecal fistula were dealt in our hospital. Out of which one presented after Incision & Drainage of neglected obstructed inguinal hernia which was misdiagnosed as inguinal abscess and the other one presented with spontaneous fecal fistula. These two cases were managed in a similar manner with exploratory laparotomy and resection of obstructed fistulous ileal loopswith end to end Ileo-ileal anastamosis. Herniorrhaphy was done and inguinal area left opened for healing by secondary intention.

Two cases of incisional hernia with enterocutaneous fistulas were treated. One had the history of previous laparatomy and incisional hernia surgery, and the other had the history of previous 2 Caesarean sections and incisional hernia surgery. Exploratory laparotomy with resection of involved part of small intestine and end to end anastamosis of normal bowel was done. In first case, the previously placed mesh was found eroding into the bowel lumen and it was removed. Anatomical reconstruction of anterior abdominal wall was done in both the cases.

Three cases of Amayand's Hernia were managed. Intraoperatively, there was caecum with inflamed appendix as the content of hernia sac in both the cases. Appendicectomy with Hernioplasty was done.

One case of very rare Thoracic hernia was diagnosed. A60 year old male presented with a bulge over left chest wall since one year. The swelling was moving with respiration and coughing. He didn't have any history of thoracic surgery or chesttrauma. USG& HRCT chest showed a protrusion of lung through the intercostal space during valsalva and coughing. He was a known case of chronic obstructive pulmonary disease with severe pulmonary hypertension. Intervention was not done because patient was not fit for surgery.

Table 2: Showing post-op complications, postoperative stayand herniarecurrences.

Type of Hernia	Total no of cases	Post-op complications				Average post-operative stay(days)	Recurrences after 1 year
		Seroma	Infection	Wound dehiscence	Mesh infection		
SPC site hernia	2	1	0	0	0	8	No
Femoral hernia	3	2	0	0	-	5	No
Inguinal heruia presenting as fecal fistula	2	1	1	0	-	10	No
Incisional hernia with enterocutaneous fistula	2	1	1	1	-	15	No
Amayand's hernia	3	1	0	0	0	5	No
Total	12	6	2	1	0		-

Above table highlights the post operative complications and overall hospital stay after surgery. We found that the most common complication was Seroma formation that was seen in 6 out of 12 patients operated (50%). Wound infection was seen in 2 patients (16.66%), while wound dehiscence was seen in only 1 patient (8.33%).

The polypropylenemesh was placed in 5 of the 12 operated patients but mesh infection was not seen in any of them.

Out of two patients of inguinal hernia with fecal fistula, one patient developed Seroma while the other had wound infection. Out of the two patients of incisional hernia with enterocutaneous fistula, one patient developed only Seroma, and the other developed wound infection and later on, wound dehiscence also.

In cases of femoral and amayand's hernia , the only complication seen was Seroma formation that developed in 2 out of 3 femoral hernia cases and 1 out of 3 Amayand's hernia cases.

al[11] from Nigeria reported the case of a neglected Richter's inguinal hernia presenting with perforation and Fournier's gangrene. Three cases of spontaneous perforation of Richter's inguinal hernia with Fournier's gangrene were reported by Guzzo et al[12] in 2007 from the United States of America. One of our patient presented with spontaneous onset fecal fistula without any previous signs and symptoms of hernia and the other was a neglected undiagnosed obstructed inguinal hernia which was misdiagnosed as an inguinal abscess at the periphery and disastrous I & D was done. These finding were very unusual and final diagnosis was established by CECT abdomen and surgery was done. We do not recommend the use of mesh in the setting of abscess or fecal fistula. A good tightening of deep ring during laparotomy and free drainage from fistula site leads to healing and recurrence is prevented.

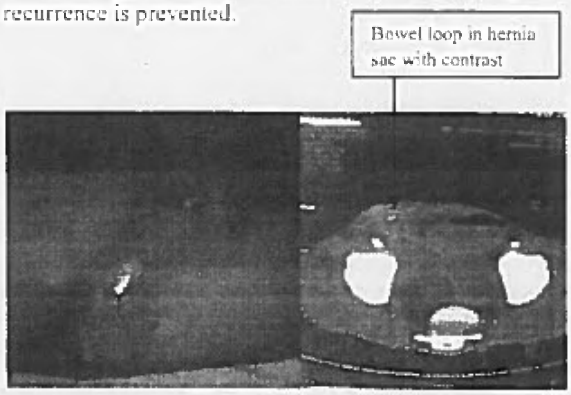

Figure 3 (a): Pre op. Figure 3 (b): CT scan.

Figure 3 (c): CT scan. Figure 3 (d): Post op.

Figure 3: Inguinal hernia as fecal fistula.

Incisional hernia with enterocutaneous fistula

Mesh hernia repair is a fairly common technique used to treat incisional hernias. Meshes have advantages and disadvantages. Whether meshes can cause enterocutaneous fistula, is a matter of debate. There are some studies which are against this possibility,[13,14] but there are also some studies in support of it.[15,16] In our case series, both the patients presented with recurrence of hernia along with enterocutaneous fistula few years after mesh repair for incisional hernia. In the first case, the incisional hernia had developed after Laparotomy, and in the other, the incisional hernia had developed after previous 2 Caesarean Sections. This suggests that a mesh can erode the bowel and that patients have a lifelong risk of this complication. We recommend the removal of whole involved mesh along with the resection of the involved part of intestine in such setting. The Anatomical repair of hernia can be done in such cases where the use of mesh is not indicated.

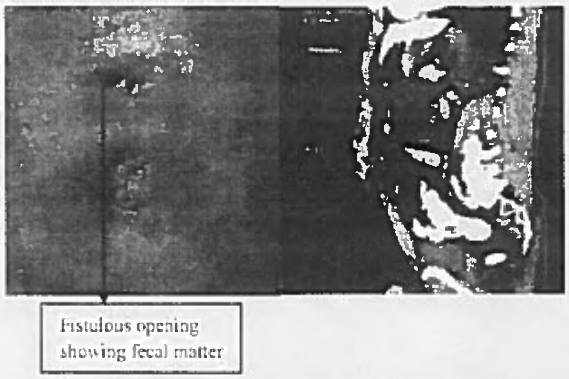

Figure 4 (a): Pre op. Figure 4 (b): CECT.

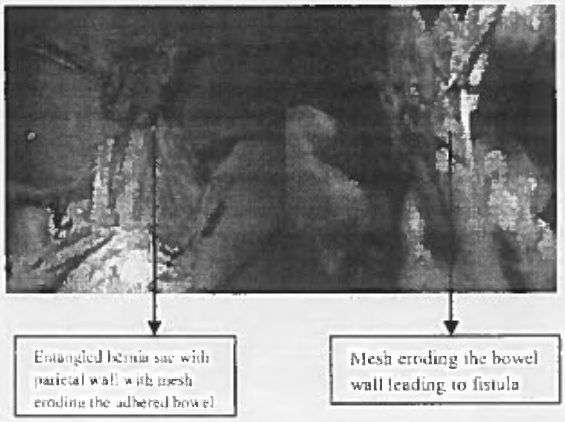

Figure 4 (c): Intra op-1. Figure 4 (d): Intra op-2.

Figure 4: Recurrent incisional hernia presenting as multiple enterocutaneous fistula.

Amayand's hernia

Amayand's hernia is named after Claudius Amayand (1680-1740), a French refugee and English surgeon who did the first recorded successful appendectomy in a case of hernia with appendicitis. When a hernial sac contains vermiform appendix, inflamed or un-inflamed, it is called as an Amayand's Hernia. True incidence of this condition is difficult to estimate as all the cases are not registered and reported. Ryan WJ et al[17] have reported only 11 cases of appendicitis out of 8692 (0.13%) cases of hernial sacs with appendix. D. Alia et al[18] observed presence of

ABSTRACT

BACKGROUND
Necrotising enterocolitis is the commonest life threatening acquired gastrointestinal emergency of neonates in which lining of the intestinal wall gets necrosed. Although exact aetiology remains obscure, multiple factors like birth asphyxia, prematurity, low birth weight and use of certain drugs have been associated with necrotising enterocolitis.

MATERIALS AND METHODS
This observational study was carried out on 20 patients of neonatal necrotising enterocolitis in a tertiary care and referral hospital of Indore for a period of two and half years.

RESULTS
Eighty percent of patients were preterm births with low birth weight. Most of the cases (66%) presented in the first week of neonatal period. The Ileocaecal region was the most common part involved. Necrotising enterocolitis has significandly high mortality rate. In our study, 80% of cases died due to severe form of disease with associated morbidities.

CONCLUSION
With this study, we made an attempt to formulate a protocol to make an early diagnosis and to reduce the overall mortality.

KEYWORDS
Necrotising Enterocolitis (NEC), Low Birth Weight, Prematurity.

HOW TO CITE THIS ARTICLE: Kansal A, Jain R, Jain S, et al. An observational study of aetiopathogenesis, clinical profiles and management of neonatal necrotising enterocolitis. J. Evolution Med. Dent. Sci. 2016;5(100):7388-7393, DOI: 10.14260/jemds/2016/1672

BACKGROUND
Neonatal necrotising enterocolitis is the commonest life threatening acquired gastrointestinal emergency encountered in neonatal ICU in which the lining of intestine wall gets necrosed. In medical literature, clinical description of the condition matching with necrotising enterocolitis dates back to about two centuries. Siebold (1825),[1] Simpson (1838)[2] and Zilher (1883)[3] were the first few who reported cases suspected to have necrotising enterocolitis. There are few studies in the world literature, which have discussed some or the other parameter about this condition, but there was a need for a comprehensive study to analyse all the factors related to NEC.

The aim of our study was to make a comprehensive review of all the factors related to neonatal NEC and formulate a protocol to make early diagnosis by clinical picture and investigations so that management of these neonates can be improved and mortality can be reduced.

MATERIALS AND METHODS
This prospective observational study was carried out between May 2004 to Oct. 2006 in the Department of Surgery, M.G.M. Medical College and M. Y. Group of Hospitals, Indore which is a tertiary care centre of central India.

Inclusion Criteria
All the patients who were admitted with suspected diagnosis of neonatal necrotising enterocolitis and later on confirmed by diagnostic modalities and/or surgery.

Exclusion Criteria
1. Patients which did not complete full treatment.
2. Patients who did not give consent to participate in the study.

All the patients included in the study were thoroughly examined and subjected to investigations as per need. The relevant data was recorded in a fixed proforma that included demographic profile, preoperative investigations, intraoperative findings and postoperative followup. At the end of study, the tabulated data on master chart was analysed by simple descriptive statistical method of percentages. Detailed review of literature was done and results of study were compared with other studies.

Findings	Abdominal Distension	Tenderness	Rigidity	Guarding	Visible Veins	Hypothermia	Ant. Abdomen Wall Erythema
Number	20	17	14	14	2	7	5
Percentage	100%	85%	70%	70%	10%	35%	25%

Table 9. Abdomen Examination Findings at Presentation

On studying the local examination findings of abdomen [Refer table No. 9], it was observed that the most frequent sign was distended abdomen (100%). Other clinical signs were tenderness (85%), rigidity (70%), guarding (70%), visible veins over the anterior abdominal wall (10%) and anterior abdominal wall erythema (25%). About 35% patients had temperature instability in form of hypothermia.

C-reactive protein	Positive	Negative
Number	17	03
Percentage	85%	15%

Table 10. C-reactive Protein Distribution N=20

Analysis of C- reactive protein was done in all the patients of NEC [Refer Table no 10] and it was observed that seventeen out of 20 Patients (85%) had raised C reactive protein value.

Radiological Findings	Persistent Dilated Bowel Loops	Pneumo- peritoneum	Pneumatosis Intestinalis
Number	8	7	5
Percentage	40%	35%	25%

Table 11. X-Ray of Abdomen

In our study, x-ray of abdomen was done in all the cases [Refer Table No. 11].

We observed that 40% of patients had findings of persistent dilated bowel loops in the consecutive x-rays, 35% showed findings of pneumoperitoneum in their x-rays and 25% of patients had pneumatosis intestinalis, which is the hallmark of NEC.

Treatment Modalities	Surgery	Conservative
No. of Patients	11	9
Percentage	55%	45%

Table 12. Treatment Modalities Used N=20

The management of the patients was decided on the basis of clinical and radiological parameters as per the protocol. We observed that 11 patients were managed surgically and 9 patients were managed conservatively. [Refer Table No. 12].

Gross Pathological Changes	Gangrenous Bowel	Perforation in the Bowel	Oedematous Bowel	Stricture in the Bowel
No. of Patients	5	4	1	1
Percentage	45.45%	36.36%	9.09%	9.09%

Table 13. Intraoperative Findings of Bowel Involvement N=11

Out of the 20 diagnosed cases of NEC, 11 cases were operated. 2 cases were planned for surgery, but they succumbed before commencement of surgery.

The most common intraoperative finding was gangrenous bowel (5 cases) and in 4 cases there were perforations in the bowel. [Refer Table no. 13]. Oedematous bowel and Stricture in the bowel as solitary findings were observed in one case each.

In 11 surgically managed cases, Exploratory Laparotomy was the operation done. Gangrenous bowel was found on exploration in 5 patients, so resection of gangrenous bowel with stoma formation was done.

Perforation in the bowel was found in 4 patients. Among them, 2 patients were managed with resection of perforated segment with anastomosis, 1 patient with primary repair of perforation and stoma formation was done in one patient.

Oedematous bowel was the only finding in 1 patient, so only peritoneal lavage was done. In 1 patient, one stricture was found in the bowel that was smoothly passable, so the bowel was left undisturbed.

Thus, the main surgical procedure was enterostomy in our study that was done in total 6 patients [54.54%].

Bowel Involved	Ileum	Caecum	Jejunum	Colon
No. of Patients	7	2	1	1
Percentage	63.63%	18.18%	9.09%	9.09%

Table 14. Segment of Bowel Involved N=11

In our study, the ileum was the most common part of bowel involved. [63.63%] [Refer Table No. 14]. In 2 cases, caecum was involved.

DISCUSSION

Siebold (1825),[1] Simpson (1838)[2] and Zilher (1883)[3] were the first few who reported cases suspected to have necrotising enterocolitis.

First survival of neonates following surgical repair of NEC is credited to Agerty[4] in 1943. Bell[5] published a severity based classification in 1978 which was modified by Walsh and Kliegem[6] in 1986.

The clinical presentations of patients of NEC were studied. We observed that all the patients of NEC presented with complaint of abdominal distension. [Refer Table no. 8]. Half (50%) of the total patients had melaena. Similar results were found by Grosfield,[12] Niyaz[8] and Echevarria et al[22] Eighteen (90%) patients had history of poor feeding. Other presenting complaints were vomiting, regurgitation and arrest of motion/flatus.

The clinical abdominal signs of patients were recorded in our study. The most frequent signs was distention of abdomen which was observed in all patients (100%). Other clinical signs were tenderness [85%], rigidity [70%], guarding [70%], visible veins over the anterior abdominal wall [10%] and anterior abdominal wall erythema [25%]. [Refer table No. 9]. Similar results were obtained in study done by Niyaz,[8] Grosfield,[12] Narang et al[17] Hamish Hwang[23] Christopher Cardot.[10] About 35% patients had temperature instability in form of hypothermia. Similar results were obtained by Niyaz[8] Hamish Hwang,[23] Christopher Cardot.[10]

Seventeen out of 20 Patients (85%) had raised C reactive Protein. [Refer Table no. 10] Similar results were obtained by Pourcyrous M.[24]

In our study, x-ray of abdomen was done in all the cases. [Refer Table No. 11]. We observed that 40% of patients had finding of persistent dilated bowel loops in the consecutive x-rays, 25% of patients had pneumatosis intestinalis [the most pathognomonic sign of NEC] and 35% showed findings of pneumoperitoneum in their x-rays. Similar results were obtained by Grosfield[12], Andreana Butter[15] Hamish Hwang.[23]

In our study, out of the 20 diagnosed cases of NEC, 11 cases were operated. 2 cases were planned for surgery, but they succumbed before commencement of surgery.

The most common pathological finding was gangrenous bowel with ischaemia (5 cases) and in 4 cases there were perforations in the bowel. [Refer Table No. 13]. Similar results were obtained by Grosfield,[12] Alda L.Tom.[25]

Exploratory Laparotomy was the operation done in 11 patients those who were managed surgically. Gangrenous bowel was found on exploration in 5 patients, so resection of gangrenous bowel with stoma formation was done.

Perforation in the bowel was found in 4 patients. Among them, 2 patients were managed with resection of perforated segment with anastomosis, 1 patient with primary repair of perforation and stoma formation was done in one patient.

Oedematous bowel was the only finding in 1 patient, so only peritoneal lavage was done. In 1 patient, one stricture was found in the bowel that was smoothly passable, so the bowel was left undisturbed.

Thus, the main surgical procedure was enterostomy in our study that was done in total 6 patients (54.54%). Similar results were obtained in the study done by Grosfield,[12] Joao Carlos,[13] Andreana Butter[14] and W B Kiesewetter.[26]

In our study, the ileum was the most common part of bowel involved. [63.63%] [Refer Table No. 14]. In 2 cases, caecum was involved. This area being more distal to the origin of the superior mesenteric artery has less blood supply and with hypoxic insult further increases the hypoxia and tissue damage. Similar results were obtained in the study done by Grosfield,[12] Niyaz[8] Kurschied T.[27]

CONCLUSION

NEC is the most common gastrointestinal emergency in the neonates. In western world, various research project has been carried out, but in our country not so many studies have been done for the NEC. So this study was carried out in Maharaja Yashwant Rao Hospital, Indore. The following conclusions were made from the study. NEC is a disease of preterm babies as their gastrointestinal tract being immature. Low birth weight is also a causative factor in the NEC. The full-term infants had early onset of NEC. This is due to earlier enteral feeding and rapid progression of feeding. Hypoxic or haemodynamic instability results in splanchnic vasoconstriction and reduced mesenteric flow inducing mucosal hypoxia and rendering the intestine susceptible to injury. High incidence in neonates who were delivered through vaginal delivery indicates that management of high risk conditions and prevention of hypoxic stress at delivery could be important in prevention of NEC. The ileocaecal region is the most common part involved as this area is being more distal to the origin of the superior mesenteric artery and has less blood supply. Since most of our cases had severe disease with multiple risk factors like prematurity, low birth weight, hypothermia, and complications like DIC, thrombocytopenia and renal failure etc, resulting in the high mortality rate. Similar results were obtained in the study done by Odita JC.[28] Our study is a modest attempt to identify and analyse various factors affecting neonatal NEC and the results of our study paves the way for further research on this topic.

ABSTRACT

BACKGROUND

Salivary gland tumours are very common in India. The present study has analysed the incidence, clinical profile and differential diagnosis of various salivary gland tumours.

The aims of this study are to know the incidence of various salivary gland tumours in different age groups and in both sexes to know the distribution of different benign and malignant tumours in each variety of salivary glands.

MATERIALS AND METHODS

This study was conducted in a prospective and retrospective ways covering the patients admitted with salivary gland tumours in a period of 6 years from 2000 to 2006. Total 59 patients were enrolled and their data was recorded.

RESULTS

Salivary gland tumours are most common in 4th and 5th decade of life. The incidence of salivary gland tumours is almost equal in both sexes with slight female preponderance. The salivary gland most commonly found involved is the parotid. Benign neoplasms are the most common swellings of salivary glands. The most common benign tumour of salivary gland is pleomorphic adenoma. The most common location of pleomorphic adenoma is the parotid gland. The most common malignant tumour of salivary glands is mucoepidermoid carcinoma.

CONCLUSION

The present study gives some important data about salivary gland tumours and emphasises the need for a more bigger study involving a larger number of patients.

KEYWORDS

Salivary Gland Tumours, Parotid, Submandibular, Pleomorphic Adenoma.

HOW TO CITE THIS ARTICLE: Jain R, Kansal A. A comprehensive study of salivary gland tumours in a tertiary care centre of Central India. J. Evolution Med. Dent. Sci. 2017;6(15):1200-1203, DOI: 10.14260/Jemds/2017/261

BACKGROUND

It is astonishing to consider how little is known of the pathological processes that affect any organ that is so near the surface, so accessible for clinical examination, so easy biopsies, so simple to obtain secretions for analysis and that organ is salivary gland.

Controversies surrounding the diagnosis and management of salivary gland masses often involve the limits of our technology. The primary controversy often lies not in how to treat a given disease, but by what means the diagnosis can be established without doubt. The present study is a modest attempt to find out the reasonable solutions of existing controversies.

The major salivary glands include parotid glands, submandibular glands and sublingual glands. There are also approximately 750 minor salivary glands scattered throughout the submucosa of the oral cavity, oropharynx, hypopharynx, larynx, parapharyngeal space and nasopharynx.

Financial or Other, Competing Interest: None.

Salivary gland neoplasms are relatively uncommon constituting 3 to 4% of all head and neck neoplasms. The incidence of salivary gland tumours is 1 to 2 cases per 100,000 people. Majority of them arise in parotid gland (70%), whereas tumours of submandibular glands (22%) and sublingual and minor salivary glands (8%) are less common. Salivary gland neoplasms most often present as slow growing, well-circumscribed masses. Symptoms such as pain, rapid growth, nerve weakness and paraesthesias and signs of cervical lymphadenopathy and fixation to skin or underlying muscles suggest malignancy.

Present study is to know the occurrence and incidence of various types of salivary gland tumours in patients presenting to M. Y. Hospital. The clinical presentation of these tumours is analysed. The differential diagnosis of these tumours is discussed. The histopathological examination reports of all cases are followed and the results analysed.

MATERIALS AND METHODS

M. Y. Hospital is a big tertiary care hospital covering a wide area with large number of admission of patients of various surgical disorders. The study was carried out in the Department of Surgery, M. G. M. Medical College and M. Y. Hospital, Indore.

Time Period

The total duration of the study was 6 years, 3 years retrospective and 3 years prospective.

DISCUSSION

The retrospective study was done from the year 2001 to 2003 and the prospective study was done from 2004 to 2006. In the retrospective group 30 cases were included and in the prospective group 29 cases were included. Thus, total 59 cases were studied.

In the retrospective group males predominated with 56.6% of the total cases, whereas females were 43.3%. In the prospective group females predominated with 58% of the total cases, whereas males were 42%. However, in the comprehensive study, the sex ratio was found to be almost equal with female comprising 51% and male 49%. Thus, the sex ratio was 0.96 with slight female preponderance. In a similar study done by Pablo Augustin et al, they have found a higher prevalence of salivary gland tumours in females (60%).[1] In contrast, Frade Gonzalez et al[2] observed a predominance of salivary gland tumours in the male group (58.75%).

The incidence of salivary gland neoplasms was most common in the 4th and 5th decade with 42.4% of cases belonging to age group 31 - 45 years, which is similar to the finding observed by Pablo Augustin et al,[1] while Frade Gonzalez et al[2] found highest incidence in the 7th decade of age.

Next high incidence was found in the age group 46 - 60 years with 16.3% of cases. The incidence was least common in the age group > 75 years with only 2 cases (3.4%). The incidence in paediatric age group (00 - 15 years) was also less with only 6 cases (10.2%).

In our study, the most common salivary gland involved was the parotid gland. It was involved in total 40 cases (67.8%). The next common salivary gland in the frequency of involvement was submandibular gland, which was involved in 27.1% of cases. The sublingual and minor salivary gland involvement was very rare. They were involved only in 1.7% and 3.4% of cases respectively. Similar observation was made in a study conducted by Eveson JW et al[3] and Pinkston JA et al.[4]

In this study, the benign neoplasms of salivary gland were found to have higher incidence as compared to malignant neoplasm and non-neoplastic swellings; 28 cases i.e. 47.5% were benign neoplasms of salivary glands, whereas malignant neoplasms comprised 18.6% of cases. We found the similar findings in the histopathological analysis done at the Armed Forces Institute of Pathology.[5]

The incidence of malignancy was found to increase in the extremes of the age groups, i.e. in the paediatric and the geriatric age groups. Out of the total 6 no. of cases in the paediatric age group, 2 were malignant (33%). Out of the total 9 no. of cases in the age group > 60 years, 6 were malignant (66%). Similar findings were observed in a study conducted by Narala Srivani et al.[6]

Also, the incidence of malignancy was more in the sublingual and minor salivary glands as compared to parotid and submandibular salivary glands. Out of the 2 cases of minor salivary gland tumours, 1 was malignant (Incidence 50%). Only 1 case of sublingual gland tumour was noticed in our study and it was malignant (Incidence 100%). Out of the 40 cases of parotid tumours, 6 were malignant (15%). Out of the 16 cases of submandibular tumours, 6 were malignant (37.5%). The preponderance of malignant tumours in sublingual and minor salivary glands was also observed in the study conducted by Narala Srivani et al.[6]

The most common benign major and minor salivary gland tumour was the pleomorphic adenoma, which constituted 66% of the total cases studied (39 cases out of 59 studied). In our study, we found that the most common location of pleomorphic adenoma was the parotid gland (71.7%) followed by the submandibular gland (25%). We found 1 case of pleomorphic adenoma in minor salivary gland, but we did not find any case of pleomorphic adenoma in sublingual glands.

In our study, the most common malignant salivary gland tumour was Mucoepidermoid Carcinoma, which was found in 6 cases (42.85%) out of total 14 cases of malignant tumours. Similar observation was made in the study conducted by Pinkston JA et al,[4] who observed that Mucoepidermoid carcinoma was the most frequent malignant tumour (51.3%). This observation is in contrast to the study conducted by Nagler et al,[7] in which they have found that the most commonly encountered malignant tumour was adenocarcinoma (including the acinic-cell and low-grade polymorphous subtypes) (27.7%). In the study conducted by Narala Srivani et al,[6] they have found that the most common malignant tumour was adenoid cystic carcinoma followed by carcinoma, ex-pleomorphic adenoma and polymorphous low-grade adenocarcinoma.

CONCLUSION

The main Results of our Study are -

1. Salivary gland neoplasms are relatively uncommon constituting 3 to 4% of all head and neck neoplasms. The incidence of salivary gland tumours is 1 to 2 cases per 100,000 people.
2. The incidence of salivary gland tumours is almost equal in both sexes with slight female preponderance.
3. Salivary gland tumours are most common in 4th and 5th decade of life. Incidence is rare in extremes of life, i.e. in the childhood and the old age.
4. The salivary gland most commonly found involved is the parotid followed by submandibular gland. Frequency in minor salivary gland is very less, while the sublingual gland tumours are rare.
5. Benign neoplasms are the most common swellings of salivary glands. Malignant neoplasms and non-neoplastic swellings are less frequently seen.
6. Incidence of malignant tumours is high in the paediatric and old age patients. Most of the neoplasms in the middle age group are benign.
7. Most of the parotid and submandibular gland tumours are benign, while the majority of sublingual and minor salivary gland tumours are malignant.
8. The most common benign tumour of salivary glands is pleomorphic adenoma. The most common location of pleomorphic adenoma is the parotid gland.
9. The most common malignant tumour of salivary glands is mucoepidermoid carcinoma.
10. In this study, we have done a modest attempt to solve some unresolved issues regarding salivary gland tumours. We believe that there is a need for further study on this subject.

Pre Operative Magnetic Resonance Cholangiopancreatography in Laparoscopic Cholecystectomy with Special Reference to Hepatobiliary Anatomic Variations and Undetected Choledocholithiasis

Ajay Chauhan [1], Nilesh Mehta[2], Mitkumar V. Patel[3], P. P. Sharma[4], F. S. Mehta[5]

[1]Associate Professor, [2]Associate Professor, [3]3rd year PG resident, [4]Professor, [5]Professor, Department of General Surgery, Geetanjali Medical College and Hospital, Udaipur, Rajasthan

Abstract

Background: Cholelithiasis is the most common disease state involving the gallbladder and biliary tree. Approximately 5-15 % patients with gallstones are associated with choledocholithiasis. Hepatobiliary anatomic variations are common and routinely encountered during laparoscopic cholecystectomy. Among all investigations, Magnetic Resonance Cholangiopancreatography (MRCP) showed high accuracy in detecting the choledocholithiasis and hepatobiliary anatomical variations. Role of routine MRCP in patients going for laparoscopic cholecystectomy is controversial.

Method: This study was carried out on 68 patients admitted in Geetanjali Medical College and Hospital, Udaipur, Rajasthan in Department of General Surgery from August 2017 to August 2019 with the confirm diagnosis of cholelithiasis and posted for laparoscopic cholecystectomy. All patients underwent MRCP and collected data was analysed.

Results: Among 68 patients, dilated CBD was diagnosed in 4 and 13 patients by USG and MRCP respectively. CBD stone was not detected by USG in any patient but MRCP detected CBD stone in 6 patients. All 6 patients with CBD stones had age of > 50 years. Normal course with right lateral insertion of cystic duct was the most common variant and was found in 57 patients in MRCP and 62 patients intraoperatively.

Conclusion: MRCP is non-invasive, non-ionizing imaging modality having higher specificity and sensitivity for asymptomatic choledocholithiasis as well as biliary tree anomalies prior to LC. But it is a costly investigation. So its routine use in preoperative evaluation for all patients undergoing for laparoscopic cholecystectomy is advisable in patients having age of > 50 years.

Keywords: *Choledocholithiasis, Hepatobiliary anatomic variations, Magnetic resonance cholangiopancreatography, Laparoscopic cholecystectomy.*

Introduction

The most common disease state involving the gallbladder and biliary tree is cholelithiasis. Because the gallbladder concentrates bile, the concentration of solutes in the gallbladder differs from that in the rest of biliary tree. This increase in solute concentration combined with stasis in the gallbladder between meals predispose to stone formation in the gallbladder.[1] First open cholecystectomy was done by Carl Langenbuch in 1882 and it was primary treatment of gallbladder disease through the early 1990s.[2] After more than 100 years, First laparoscopic cholecystectomy (LC) was done by Erich

48.51±13.31 years. Incidence of cholelithiasis in male and female patients was common in the age group 18 to 50 years and 51 to 70 years respectively. (Table 1)

Wall thickness was found normal in both USG and MRCP in all patients preoperatively. During surgery, wall thickness was found normal in 47 patients (69.1%) while it was thickened and fibrotic in 19 (27.9%) and 2 (2.9%) patients respectively.

In present study, Dilated CBD was diagnosed in 4 patients (5.9%) by USG and in 13 patients (19.1%) by MRCP. Intraoperatively CBD caliber was found normal in all patients. (Table 2)

Table 1: Distribution of the patients according to Age & Sex

			Age groups		Total
			18 to 50 years	51 to 70 years	
Sex	Male	n	5	11	16
		%	31.25%	68.75%	100.0%
	Female	n	32	20	52
		%	61.5%	38.5%	100.0%
Total		n	37	31	68
		%	54.4%	45.6%	100.0%

Table 2: Distribution of the patients according to caliber of CBD

		Caliber of CBD		Total
		Normal	Dilated	
USG	n	64	4	68
	%	94.1%	5.9%	100.0%
MRCP	n	55	13	68
	%	80.9%	19.1%	100.0%
Intra-operative	n	68	0	68
	%	100.0%	0.0%	100.0%

In our study, CBD stone was not detected by USG in any patient. But MRCP detect CBD stone in 6 patients (8.8%). (Table 3) All 6 patients with CBD stones had age of > 50 years. 4 cases had CBD stone size of < 6 mm and 2 cases had size of > 6 mm. (Table 4)

Discussion

Gallstone diseases are one of the commonest surgical problems worldwide. Cholelithiasis is more common in females than in males. In our study, 52 patients were female (76%) and 16 patients were male (24%) (N=68). In this study, the participation of patients with different sex ratio was similar to the previous studies indicating female are more affected by cholelithiasis compared to males. In study by Al-Aubaidi T et al[11], 86 patients were female and 14 patients were male (N=100). Virzi V et al[12] found that 75 patients in their study were female out of 104 and rest 29 were male (N=104).

Current study included patients of age 18 to 70 years. The mean age of patients in our study was 48.51±13.31 years. Age of youngest male and female patient in our study was 22 years and 19 years respectively. Age of oldest male and female patients was 70 years. Rao GB et al[101] found that mean age of patients in their study was 54 years. Al-Aubaidi T et al[11] also noticed mean age of 46.8±8.1 and 45.9±9.5 in their both group. We found that highest incidences of cholelithiasis were present in age group 18 to 50 years which was 37 patients (54.4%) followed by in age group 51 to 70 years which was 31 patients (45.6%). Al-Aubaidi T et al[11] also found that highest number of patient were present in both study groups from age group of 45-55 years and second highest patients were found in age group of 55-65 years and 25-35 years in group 1 and group 2 respectively. We divided patients into two age groups, first 18 to 50 years and second 51 to 70 years. In current study we found that male patients were more common after the age of 50 years as maximum number of male patients were present in age group 51-70 years (11 patients, 68.75%) while female patients were more common in age group 18 to 50 years (32 patients, 61.5%). In study by Rao GB et al[13], male patients were common in age group 41-70 years (19 patients) while female patients were common in age group 21-40 years (27 patients).

It is also important to know the wall thickness pre operatively because thickened or fibrotic gallbladder wall cause difficulty in surgery. In our study we analysed gallbladder wall preoperatively by USG and MRCP. In all patients wall thickness was found normal by USG and MRCP. During surgery we found normal wall thickness in 47 patients (69.1%) while thickened gallbladder wall was present in 19 patients who were diagnosed as normal wall thickness preoperatively. Fibrotic gall bladder was found in 2 cases (2.9%). So the pre-operative investigations were not giving exact information about wall thickness in all cases. This concludes that MRCP as a tool to asses difficult laparoscopic cholecystectomy in view of wall thickness of gall bladder is not much helpful. In current study, difference found in wall thickness in USG, MRCP and intraoperative was significant (P value 0.000).

In current study, dilated CBD was detected in 4 cases (5.9%) without stone by USG. MRCP detected choledocholithiasis in 6 patients (8.8%). All these patients with choledocholithiasis were asymptomatic. MRCP showed dilated CBD in 13 patients (19.1%) but out of 13 only 6 patients had CBD stone. All CBD stones were removed by ECRP preoperatively. Rest cases with dilated CBD without stone on MRCP had normal LFT and no jaundice and they were diagnosed as type 1 choledochal cyst by Gastroenterologist, so they were directly posted for laparoscopic cholecystectomy (Table 3). These patients were followed up in postoperative period and none of them reported as retained bile duct stones or biliary leak, etc. This suggests that even if the LFT is normal, there are chances of CBD stones and MRCP is helpful in diagnosis of these cases. Result of our study was statistically significant (P value = 0.012).

Singh S et al[14] observed different sizes of CBD stones in MRCP. They found 7 cases of CBD stone with stone size ≤ 6 mm and 13 cases with stone size > 6 mm. The smallest stone detected by MRCP was 4 mm in diameter. In current study we observed that out of 6 cases of CBD stone detected by MRCP, 4 cases had CBD stone size of < 6 mm and 2 cases had > 6 mm. The smallest stone size was 4 mm. In study by Al-Aubaidi T et al[11] they found 2 cases of CBD stone detected by MRCP. Both these patients had age of > 45 years. In our study all 6 cases of CBD stone had age of > 50 years. Youngest patient with CBD stone was 51 years old and oldest patient with CBD stone was 70 years old. We conclude that there are higher chances of CBD stone in and after 5th decade of life. All patients having age of > 50 years must be investigated with MRCP before laparoscopic cholecystectomy because of higher chances of CBD stones in these patients. (Table 4)

ABSTRACT

Introduction : Varicose veins are most common in the superficial veins of the legs, which are subject to high pressure when standing. Besides cosmetic problems, varicose veins often itch and are painful, especially when standing or walking. Though varicose veins rarely present with an acute emergency or life threatening complication, symptoms like dragging sensation, heaviness, pain, bleeding, ulceration or lipodermatosclerosis require an active intervention to get relief from the disease. A new approach to management of saphenous vein reflux is endovascular obliteration of the vein with a radiofrequency generated heating probe placed through a percutaneous puncture or mini incision in the calf. The procedure is less invasive and may, therefore result in shorter convalescence and ability to resume work sooner, thus reducing the costs of the productivity. Any alternative technique to high ligation and stripping must ideally have the same or better outcome but without the associated morbidity.

Aims And Objectives: To assess and compare the efficacy of Trendelenburg and Stripping with RFA of GSV for the management of primary varicose veins in Indian setup.

Materials And Methods: Patients divided into two- Ligation-Stripping(LS) group (n=30) and; Radiofrequency Ablation(RFA) group (n=30). Patients were given a questionnaire (Likert's questionnaire) consisting of six questions to fill on postoperative day 3, 7, 28 and at 90 days.

Conclusion: Radiofrequency ablation of GSV for the treatment of varicose veins, is as effective as High ligation and stripping. The two procedures are comparable in terms of quality of life indicators, postoperatively, but the cost of RFA procedure is almost 3 times higher than the LS procedure of GSV.

KEYWORDS

Ligation-Stripping (LS); Radiofrequency Ablation (RFA); GSV; Trendelenburg; Saphenous Vein; Varicose Vein.

INTRODUCTION

Varicose veins are most common in the superficial veins of the legs, which are subject to high pressure when standing. Besides cosmetic problems, varicose veins often itch and are painful, especially when standing or walking. Though varicose veins rarely present with an acute emergency or life threatening complication, symptoms like dragging sensation, heaviness, pain, bleeding, ulceration or lipodermatosclerosis require an active intervention to get relief from the disease[1].

Non-surgical treatments include, compression elastic stockings, elevating the legs, and exercise. The traditional surgical treatment has been vein stripping to remove the affected veins. Because most of the blood in the legs is returned by the deep veins, the superficial veins, which return only about 10 per cent of the total blood of the legs, can usually be removed or ablated without serious harm[2]. Conventional surgery (stripping of the veins) has been the time tested modality of treatment for varicose veins.

The treatment of varicose veins has undergone vast research and modification in its course. The three mains categories of primary venous insufficiency are: telangiectasias, reticular varicosities, and varicose veins, all being physiologically similar, differing only in the caliber. The unifying end result is dilated, tortuous, elongated veins with dysfunctional or non-functional valves. Operations on varicose veins are amongst the most common surgical procedures. In the conventional management of the incompetent saphenous vein in patients with symptomatic varicose veins, it is generally believed that the best treatment is removal of the great saphenous vein (GSV) from the sapheno-femoral junction to the level of knee or below, along with individual ligation of the saphenous tributaries in the groin. The stripping operation is a relatively inexpensive day surgery procedure that needs no special instrumentation. Varicose vein surgery though regards as a safe and minor procedure[3] is nevertheless associated with significant surgical morbidity and dissatisfaction. Flush ligation and stripping of the GSV is standard treatment for varicose veins with highest rate of initial success and lower rates of recurrence. But recurrence rates as high as 10% at 5 years have been reported, and approximately 5% of varicose veins operations are done for recurrence, most common cause of recurrence being neovascularisation at the saphenofemoral junction.

But newer modalities have arisen which are less invasive. Newer, less invasive treatments, such as ultrasound-guided foam sclerotherapy, radiofrequency ablation and endovenous laser treatment, are slowly replacing traditional surgical treatments. Further experience with these procedures will help to determine which one will become method of choice for treating this complex disease process.

Increasingly well informed patients who pressure the treating surgeon for cosmetically acceptable results in conjunction with expansion of minimally invasive techniques have made the treatment of superficial venous reflux and varicose veins a rapidly evolving field. It is very likely that some of these procedures like RFA will replace the procedures that we currently use today[4]. In our study we will focus on the various aspects of conventional surgery and radiofrequency ablation and make a comparison between the two modalities.

A new approach to management of saphenous vein reflux is endovascular obliteration of the vein with a radiofrequency generated heating probe placed through a percutaneous puncture or mini incision in the calf. The procedure is less invasive and may, therefore result in shorter convalescence and ability to resume work sooner, thus reducing the costs of the productivity.

Any alternative technique to high ligation and stripping must ideally have the same or better outcome but without the associated morbidity.

AIMS AND OBJECTIVES

To assess and compare the efficacy of Trendelenburg and Stripping with Radiofrequency Ablation of Great Saphenous Veins for the management of primary varicose veins in Indian setup.

MATERIALS AND METHODS

This is a prospective randomized study conducted in the Department of General Surgery, and Department of Radio diagnosis at GMCH,

withdrawing the catheter 7 cm at a time. Percutaneous foam sclerotherapy of varicose vein is performed 50% STDS form without opacifying the deep system. The procedure was done by Consultant Interventional Radiologist. Efficacy outcome was assessed on the following parameters at baselines, 3 days, 7 days, 28 days, 3 months. Adverse events/complications were recorded along a checklist prepared for this study (intraoperative, postoperative day 3, 7, 28, 90). Patients were given a questionnaire (Likert's questionnaire) consisting of six questions to fill on postoperative day 3, 7, 28 and at 90 days. The patients marked their response as 100- definitely true; 50- can't say, 25 mostly false, 0 definitely false. The response was assessed with median and percentage.

Questionnaire

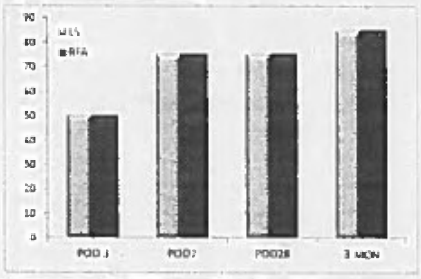
1. Was helped as much as I thought I will be post surgery.
2. My problem/ problems were reduced as much as I expected them to after surgery.
3. The benefit of my care outweigh the setback it caused me.
4. Overall I am happy with the care I am receiving for my legs.
5. All things considered, I would have the surgery again for the same reason.

RESULTS

Table 1: Distribution of Patients According to Presenting Signs and Symptoms to Type of Skin Involvement to Limb Involvement

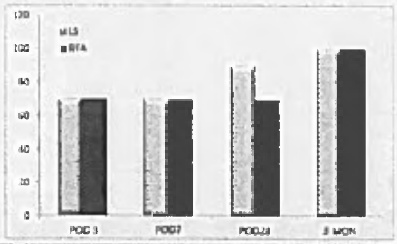
Factors	Stripping & flush ligation group (n=30)	Radio-frequency Ablation group (n=30)	P-value
Ulceration	None	None	-
Pain	13	9	NS
Itching	None	None	-
Skin involvement	12 (40%)	10 (33.33%)	NS
Left	25 (83.3%)	25 (83.3%)	NS
Right	5 (16.67%)	5 (16.67%)	
No. of incompetent perforators	15 (0-3)	15 (0-3)	NS

Graph 1: Response to "I was helped as much as I thought I will be post surgery" (values in median)

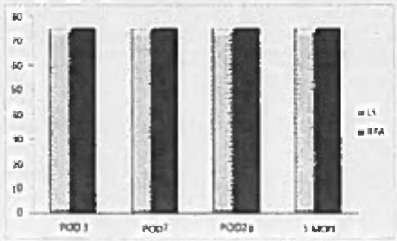


Graph 2: Response to "My problem/problems were reduced as much as I expected them to after surgery" (values in median)

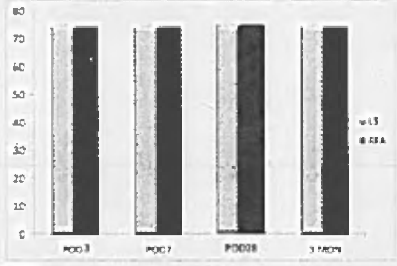
Graph 3: Response to "the benefit of my care outweigh the setback it caused me" (value in median)



Graph 4: Response to "Overall I am happy with the care I am receiving for my legs" (value in median)



Graph 5: Response to "All things considered, I would have the surgery again for the same reason" (value in median)



DISCUSSION

Treatment of varicose veins has been a topic of research and the search for adequate and ideal treatment of this common condition has seen various stages of evolution, ranging from conservative compression stocking to the most recent endovenous laser application. However, surgery in the form of high flush ligation of SFJ and striping of GSV has been traditionally described as the gold standard. Beale and colleagues in 2005, did a review of the various treatment options being used in the treatment of this disease'.

Operative treatment strategies can be minimally invasive ones, like RFA and EVLA, or conventional techniques like flush ligation with striping of GSV with its modifications. In RFA, the vein is cannulated at knee level using a 5-8Fr diode catheter and advanced to SFJ under USG control and then withdrawn slowly. Application of heat result in endothelial denudation, collagen denaturation and the actual vein contraction. The technique is suitable for veins upto 12mm diameter, thus not being applicable to all the patients.

Complications associated with this technique, apart from recanalisation, include thermal burns, saphenous neuritis, and DVT. Other minimally invasive endovenous technique is laser ablation. In this, the vein does not immediately shrink, but does so over a period of 6 weeks, then it eventually disappears. Main complications are bruising and thrombophlebitis, with less evidence of burns, paraesthesia and DVT. Complications associated with formal surgery include nerve injury, hematoma, wound infection, thromboembolism and recurrence.

Over the years, with the advancement of technology and the advent of radiofrequency and laser, and their application in surgical practice, has made these minimally invasive techniques lucrative treatment options. Proponents of these procedures claim to overcome the morbidity and complications associated with LS of GSV, but these techniques are not flawless and have their own complications.

In our study we compared the two procedures and assessed the outcomes in terms of occlusion rates, the complication rates and QOL measures. We found that we could achieve 100% occlusion rates in both the procedures, we did not find any statistically significant difference in the complication rates and the patients did not show any predilection towards any one specific mode of treatment. The cost of radio frequency ablation procedure is almost three times higher than the trendenburg and stripping procedure of GSV. We found that the two procedures were comparable to each other, in terms of the incidence of complications and recurrence of disease in our duration of study.

The clinical stage of disease, showed an improvement in all the treated patients regardless of the procedure they underwent. Deep vein thrombosis was not seen in any of the patient. We measured QOL indicators using direct questions and used a questionnaire which was based on Likert's scale. The responses did not show any significant

Treatment of Liver Abscess: A Comparison of Catheter Drainage and Needle Aspiration

Ajay Chauhan[1], Yashasvi Patel[2], P. P. Sharma[3], F. S. Mehta[3]

[1]Associate Professor, [2]3rd Year PG Resident, [3]Professor; Department of General Surgery, Geetanjali Medical College and Hospital, Udaipur; Rajasthan

Abstract

Background: The aim of the study was to evaluate the clinical presentation, and to investigate the effectiveness of continuous catheter drainage in comparison to needle aspiration in the treatment of liver abscesses.

Method: This is a comparative study of 50 patients, presented in outpatient and emergency department at the hospital,equally into two groups,

percutaneous needle aspiration and pigtail catheter drainage. The effectiveness of either treatment was measured in terms of duration of hospital stay, days to achieve clinical improvement, 50% reduction in abscess cavity size and total/near total resolution of abscess cavity.

Results: The success rate was significantly better in catheter drainage group. The patients in pigtail catheter drainage group showed earlier clinical improvement and decrease in abscess cavity volume as compared to those who underwent percutaneous needle aspiration.

Conclusions: Percutaneous catheter drainage is a better modality as compared to percutaneous needle aspiration especially in larger abscesses which are partially liquefied or with thick pus.

Keywords: *Liver abscess, Catheter drainage, Needle aspiration*

Introduction

Liver abscess has been recognized since hippocrates (400 B.C.)who speculated that the prognosis of patients were related to the type of fluid within the abscess cavity[1]. A liver abscess is a suppurative cavity in the liver resulting from the invasion and multiplication of microorganisms, entering through the blood vessels or by the way of the biliary ductal system. It is the commonest infection affecting liver. Liver comprises 48% of all the visceral abscesses[2]. Liver abscess is the constant source of mortality in developing country. India being a developing country, a large proportion of population living under poverty line, a good amount of people are predisposed to liver abscess. It is common in India with 2nd highest incidence due to poor sanitation, overcrowding and inadequate nutrition[3]. Prevalence of infection is higher than 5%-10% in endemic areas[4].

Liver abscess is a major tropical disease of the gastrointestinal system which is mainly classified into amoebic and pyogenic. Pyogenic liver abscess which used to be mainly tropical in location. Majority of liver abscess cases from developing country are of amoebic etiology.[5]

Liver abscess is found more commonly in men between 20 and 40 years of age but can occur at any age. Approximately 60% of the abscesses are solitary and mainly located in the right lobe of the liver, as a result of the streaming of the portal blood flow secondary to

Results

In presenting study the age group of the patients ranged from the 20-72 years.

Highest incidence(66%) was found between 3rd - 4th decades. In this study

45 patients were male and 5 patients were female and ratio being, male : female was 9:1. 40 patients were from rural and 10 were from urban population and the incidence of alcohol consumption was 72%.

In present study, all patients gave history of right upper quadrant dull aching pain associated with anorexia and Fever. (Table 1)

Table 1: Symptoms & signs of liver abscesses (n=50)

Characteristic	Percutaneous needle aspiration(n=25)	Percutaneous catheter drainage (n=25)
Right upper quadrant pain	100%	100%
Right hypochondruim tenderness	100%	100%
Anorexia	100%	100%
Fever	96%	96%
Nausea & vomiting	60%	60%
Hepatomegaly	52%	88%
Respiratory symptoms	12%	32%
Jaundice	08%	12%
Diarrhoea	0%	0%

It was observed that 96% had leucocytosis (Table 2).

Table 2: Laboratory Data of all patients (N=50)

Investigation	Percutaneous needle aspiration (n=25)	Percutaneous catheter drainage (n=25)
Leucocytosis (>11000)	84%	100%
Elevated S. Bilirubin Total	12%	24%
Elevated SGOT	64%	84%
Elevated SGPT	64%	100%
Hypoalbuminemia	52%	96%
Elevated Alkaline phosphatase	64%	92%
Elevated INR	64%	88%

In the present study, 38(76%) patients had solitary abscess and 12(24%) patients showed multiple abscesses. 41(82%) had right lobe involvement, 6(12%) had left lobe involvement and 3(6%) had both lobes involved. Volume of abscess was measured, the smallest was 65 cc and the largest was 1200cc. It was observed that the volume of the abscess cavities was mostly between 150-350cc. Pus aspirated from all abscesses was sent for culture and sensitivity. Cultures were found to be positive in 16(32%) cases. The rest were sterile. Amoebic liver abscesses were encountered more frequently (68%) compared to pyogenic (30%). Only 1 (2%) case was encountered with mixed of liver abscess.

lobe abscesses were more common.

Amoebic abscesses were more common finding than pyogenic abscesses in our study. These findings were comparable with **Singh et al** study.

We performed image-guided percutaneous intervention in 50 patients. Their response to treatment was recorded and analyzed. Same results of PNA and PCD were reported by **Bansal et al**[18].

The time required for 50% reduction in the cavity size was significantly less in the PCD compared to PNA group. However, time required for total or near-total resolution of the abscess cavity did not show any significant difference in the two group. It can be concluded that the abscess cavities showed faster collapse during the initial period in the PCD group but it did not have an advantage as far as total or near-total resolution of cavity is concerned. Similar result were recorded by other researcher as **Rajak et al**[19].

Needle aspiration is simple, safe & acceptable treatment of choice in liver abscess less than 5cm in diameter under US guidance. The major advantages of PNA are easy to perform as a outdoor procedure, less invasive, less expensive with medical & nursing care, avoids problems related to catheter care, multiple abscess cavities can be aspirated easier in the same setting[20]. Inability to completely evacuate the Large (>5 cm) abscesses, thick viscous pus and rapid re-accumulation of pus are the important reasons for failure of needle aspiration[21]. Placement of an indwelling drainage catheter addresses all of these issues. This explains the higher success rates of PCD treatment group observed in our study and several previous studies[22].

Conclusion

Our study concludes that the percutaneous catheter drainage is a better and effective percutaneous treatment modality as compared to percutaneous needle aspiration in view of greater volume of pus drained in first sitting, in respect to clinical improvement, resolution of cavity, success rate but there was no significant morbidity - mortality occur during both the procedure.

A Prospective, Randomized, Controlled Study For Efficacy of Phenytoin Sodium Powder, Eusol Solution, Nanocrystalline Silver Gel in Diabetic Foot Ulcer

Ajay Chauhan[1], Bhavesh K. Patel[2], P. P. Sharma[3], F. S. Mehta[4]

[1]Associate Professor, [2]3rd year PG Resident, [3]Professor, [4]Professor, Department of General Surgery, Geetanjali Medical College and Hospital, Udaipur, Rajasthan

Abstract

Background: Diabetic foot is one of the most significant and devastating complications of diabetes. Not all foot complications can be prevented, but it is possible to dramatically reduce their incidence through appropriate management and prevention. Various dressings are available that fulfils a number of functions like cosmesis, haemostasis, protection, support and absorption.

Objectives: To study and compare the efficacy of different topical agents like phenytoin sodium powder, eusol solution, nanocrystalline silver gel in patient with diabetic foot ulcer by recording the mean ulcer size pre-treatment, during the course of treatment (1 week, 2 week, 3 week and 4 week follow up) and post- treatment and mean percentage of the wound size healing after treatment.

Material & Method: This prospective study was conducted in the Department of General Surgery, Geetanjali Medical College & Hospital, affiliated to Geetanjali University from January 2017 to June 2018. 90 patients with diabetic foot ulcers without any other co-morbid conditions and ulcers belonging to Grade I & II as per Wagner diabetic foot ulcers classification were compared with the efficacy of different topical agents.

Results: Out of 90 patients, there was a highly significant reduction in the mean ulcer size after 2 week, 3 week and 4 week follow up in nanocrystalline silver gel group ($p<0.05$) as compared to the phenytoin sodium powder and eusol solution group and the formation of granulation tissue was higher in nanocrystalline silver gel group (90%) as compared to phenytoin sodium powder (80%) and eusol solution (73.33%).

Conclusion: Dressings done with nanocrystalline silver gel was found to be more efficacious than the other topical agents in patients with diabetic foot ulcers in terms of increased rate of wound healing, greater reduction in the mean ulcer size after treatment, absence of pain, swelling and type of discharge after treatment, greater incidence of formation of granulation tissue and less duration of antibiotic therapy and hospital stay.

Introduction

Diabetic foot is one of the most significant and devastating complications of diabetes, and is defined as a foot affected by ulceration that is associated with neuropathy and ischaemia of the lower limb in a patient with diabetes [1]. In India, diabetic foot

Grade 3- deep ulcer with abscess

Grade 4- gangrene limited

Grade 5- gangrene extensive.

Patients were then subjected for detailed clinical examination with baseline investigations, were posted for surgical procedures (debridement) if required & follow up of patients during hospital stay and at 1st, 2nd, 3rd and 4th week was done. We did dressings of patients as required until wound healing achieved and changes in wound size (area of the wound was measured in square centimeters by taking an impression of the wound on a gauze piece and tracing it on graph paper on subsequent days) was recorded when the dressing was removed and changed. phenytoin sodium powder group, eusol solution group and nanocrystalline silver gel group to compare the effectiveness of these different topical agents on patients with diabetic foot ulcer in regards of presence of pus, swelling, pain before treatment and after treatment, mean ulcer size pre-treatment, during the course of treatment (1 week,2 week, 3 week and 4 week follow up) and post-treatment, mean percentage of the wound size healing after treatment, duration of antibiotic therapy, duration of hospital stay and formation of granulation tissue.

The quantitative data was represented as their mean ± SD. Categorical and nominal data was expressed in percentage. The t-test was used for analysing quantitative data, or else non parametric data was analyzed by Mann Whitney test and categorical data was analyzed by using chi-square test. Pearson's correlation coefficient was used to determine the correlation between parameters. The significance threshold of p-value was set at <0.05. All analysis was carried out by using SPSS software version 20.

Results

A total of 90 patients were included in the study under the age group of 40-70 years. Males (71) were more affected than females (19). Pain after treatment-lower pain scores in the nanocrystalline silver gel group (1.20 ± 1.24) as compared to the phenytoin sodium powder (2.03 ± 1.45) and eusol solution group (1.87 ± 1.57).

Table 1: Presence of Pain (VAS) after Treatment in all 3 groups

Pain (VAS)	Phenytoin Sodium Powder		Eusol Solution		Nanocrystalline Silver Gel	
	No.	%	No.	%	No.	%
0	7	23.33%	9	30.00%	12	40.00%
1	3	10.00%	4	13.33%	7	23.33%
2	8	26.67%	6	20.00%	5	16.67%
3	6	20.00%	4	13.33%	5	16.67%
4	6	20.00%	7	23.33%	1	3.33%
Mean±SD	2.03	1.45	1.87	1.57	1.20	1.24

The mean ulcer size was significantly smaller in the nanocrystalline silver gel group (3.41 ± 3.17) as compared to the phenytoin sodium powder (9.21 ± 7.41) and eusol solution (7.72 ± 6.65) group after 4 weeks follow up ($p<0.05$). Also, there was a highly significant reduction in the mean ulcer size after 2 week, 3 week and 4 week follow up in nanocrystalline silver gel group ($p<0.05$) as compared to the phenytoin sodium powder and eusol solution group.

Table 5: Duration of hospital stay in all 3 groups

	Phenytoin Sodium Powder		Eusol Solution		Nanocrystalline Silver Gel	
	Mean	SD	Mean	SD	Mean	SD
Duration (days)	14.97	5.73	13.30	4.48	10.27	5.27

Table 6: No. of Weeks and Dressings Required for Wound Healing in all 3 groups

	Phenytoin Sodium Powder		Eusol Solution		Nanocrystalline Silver Gel	
	No.	%	No.	%	No.	%
1 week	1	3.33%	0	0.00%	2	6.67%
2 weeks	6	20.00%	6	20.00%	8	26.67%
3 weeks	8	26.67%	8	26.67%	11	36.67%

Total	24	80.00%	22	73.33%	27	90.00%

Discussion

Diabetic foot ulcer is one of the most devastating complications of diabetes mellitus and early effective management can reduce the severity of complications such as preventable amputations and possible mortality and can also improve the quality of life. Topical phenytoin is a known inexpensive therapeutic agent in wound healing as it induces growth of granulation tissue, angiogenesis and decreases the wound size. Eusol is a commonly used solution for wound healing as it is a desloughing agent and helps in effective healing. Nanocrystalline silver gel also promotes wound healing through the antiseptic, antimicrobial and anti-inflammatory properties of silver.

In our study, after treatment and follow-up of 4 weeks pain scores in all the three groups reduced, however, there was much lower pain scores in the nanocrystalline silver gel group (1.20 $\pm$ 1.24) as compared to the phenytoin sodium powder (2.03 $\pm$ 1.45) and eusol solution group (1.87 $\pm$ 1.57). Ramanaiah et al [8] also found a significant reduction in the pain scores in the nanocrystalline silver gel group post treatment in their study. Similarly, in a study done by Jayalal et al [9] on efficacy of topical phenytoin sodium powder in diabetic foot ulcer, pain scores were found to be significantly lower in the study group as compared to the control group.

Our study showed that the mean ulcer size after 1 week, 2 week and 3 week follow up in silver group reduced more as compared to the phenytoin sodium powder and eusol solution group. Similarly, Ramanaiah et al [8] found significant reduction in the wound size in their study after treatment with nanocrystalline silver gel dressings. Sharma et al [10] also found a significant reduction in the wound size with an effective wound healing with nanocrystalline silver gel dressings as compared to the conventional dressings.

In a study done by Jayalal et al [9] on the efficacy of topical application of phenytoin sodium powder in diabetic foot ulcer, there was a significant reduction in the slough and wound size area after treatment. Charne et al [11] demonstrated nanocrystalline silver gel had a much higher rate of healing ulcer size compared to other applications.

In our study, mean percentage of wound size healing of ulcer with nanocrystalline silver gel dressing is 83.07% as compared to the phenytoin sodium powder (57.98%) and eusol solution (63.69%).

ABSTRACT

Background: Every hour, 40 people under the age of 25 die in road accidents around the globe. According to the WHO, this is the second most important cause of death for 15 to 29 year olds. According to the latest report of National Crime Records Bureau or NCRB, Over 1, 37,000 people were killed in road accidents in 2013. Thoracic trauma forms one of the major parts of multiple traumas and is responsible for significant mortality and morbidity especially at younger ages.
Methods: We carried out a retrospective study to assess the prevalence of chest injury patients at Geetanjali medical college and hospital, Udaipur (Tertiary care rural centre) in last two years. Clinical details of the patients were recorded from their case sheets and were analyzed with reference to their age, sex, mode of injury, severity of injury, treatment employed, complication and final outcome etc.
Results: Males were predominantly involved (88.2%). Majority (61.9%) were in the age group of 21-30 years.
Conclusions: Chest injury occurs in a significant number of trauma patients and commonly affected victims are males of 20-40 years age. The majority of these patients were managed by simple intervention i.e., intercostals chest tube drainage and non –invasive ventilation, only less than 3% require thoracotomy.

Keywords: Blunt trauma, Flial chest, Haemothorax, Inter costal chest tube drainage

INTRODUCTION

Accidents which are unexpected and unplanned events are becoming the major epidemic of non-communicable disease in the present century. The number of accidental deaths in India is even higher than in the Western World[1]. Thoracic trauma contributes heavily to these figures which may present as isolated injury or as a part of polytrauma. Blunt thoracic injuries are thought to result from a combination of crushing, compression, stretching and shearing forces. The magnitude of these forces directly related to the rate of their acceleration and deceleration and also their relative direction of impact. Although most of the fractures of bony thorax are benign entities and can be followed up without hospitalization, trauma limited to the thoracic cage itself may cause profound pathophysiological alterations, which may be fatal if not promptly treated. On the other hand, the accurate identification of a patient at high risk for major chest trauma is essential for regulation of over and under triage within a trauma system. The present study focuses on blunt chest injuries, especially rib fractures and associated injuries. In spite of the high mortality rates, about 90% of the patients with life-threatening thoracic injuries can be managed by a simple intervention like intercostals tube drainage and non invasive ventilation.[2]

Single rib fracture was evident on x-ray in 56 patients, two fractured ribs were seen in 186 patients and in 410 patients there were multiple ribs fractured. In 46 patients, multiple rib fractures were also associated with flail chest. In 30 cases there was no evidence of fractured ribs on x-ray but still they developed either pneumothorax or haemopneumothorax or occult pneumothorax.

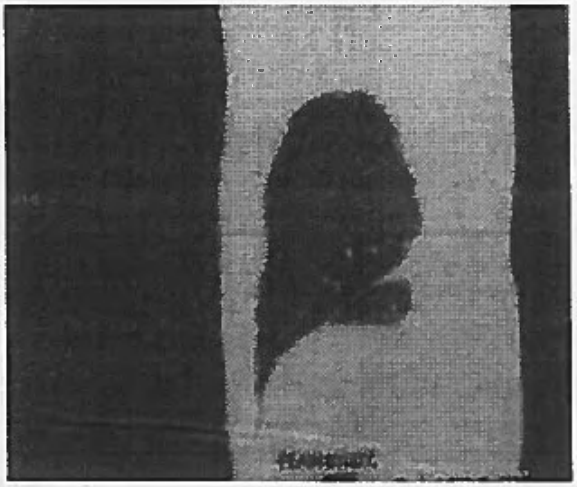

Figure 3: CT- THORAX showing occult pneumothorax.

Rib fractures were associated with subcutaneous emphysema in 186 patients (25.47%). Hemo/pneumothorax with subcutaneous emphysema was observed in 89 patients (12.19%). Subcutaneous emphysema without another complication was observed in 42 patients (5.75%), in most of patients it resolve spontaneously.

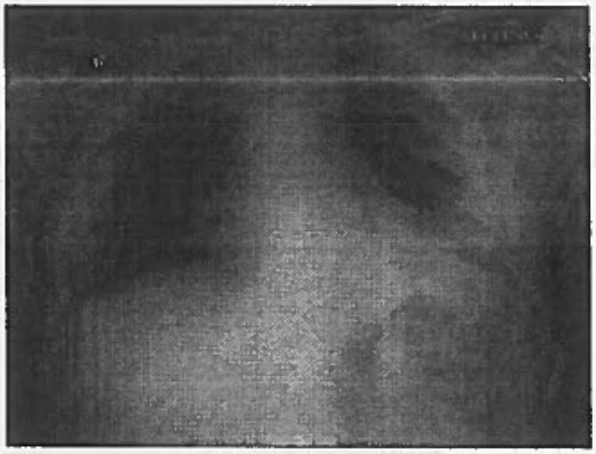

Figure 4: X-Ray chest showing surgical emphysema associated with flial chest.

Hemo-/pneumothorax were observed in 437 patients (59.86%) with rib fractures: In 13 (2.97%) patients with single rib fracture, in 109 patients (24.94%) with two rib fracture and 315 patients (72.08%) in more than two rib fractures out of 437 patients. The differences between the groups were statistically significant (P<0.001).

Table 4: Treatment modality.

Treatment	Number of patients	Percentage
No. active treatment	225	30.82
ICTD	331	45.34
Thoracotomy	12	1.64
Non invasive ventilation	134	18.35
Invasive ventilation	28	3.83

Chest tube drainage was performed in 331 patients with pneumothorax, hemothorax or hemopneumothorax. Patients with minimal (<20%) pneumothorax followed without chest tube drainage and patients with minimal hemothorax underwent thoracentesis alone. Chest tube was performed successfully in all. But five of these patients required thoracotomy (in 4 patients with massive bleeding, one patient with chylothorax).

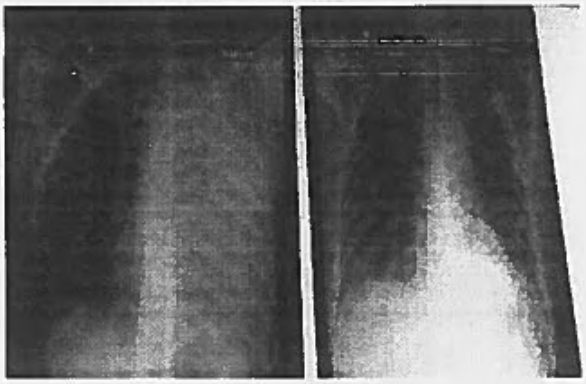

Figure 5: Inter costal tube drainage for left haemothorax.

46 patients presented with flail chest. All patients with flail chest were kept in the Intensive Care Unit. The management of these patients was based on the trend of serial measurements for arterial blood gases and serial x-ray chest PA view. In all patients with flail chest, tube thoracostomies was done and patient was put on non invasive ventilation whenever required. Analgesia was provided through administration of parenteral analgesics and epidural analgesics. In 10 of these patients, percutaneous tracheotomy was performed aiming suctioning of secretions and giving oxygen to the patients more effectively (reduction of dead space). These patients developed acute respiratory failure and invasive mechanical ventilation was indicated. In spite of aggressive critical care management seven patients died out of 46. Mean hospitalization time for these patients was 23 days.

patient. The incidence of empyema has been reported about 2 to 3 percent in patients with chest injury requiring tube thoracostomy in various studies.[6,12]

Overall, there were 17 deaths in this series, with most of patients having multiple fractures with flail chest and massive pulmonary contusions associated abdominal injuries and pelvic fracture. The mortality rate after severe chest injury was comparable with other studies reported in the literature.[12] The clinical state of the patient, severity of the trauma, age, presence of more than two rib fractures, presence of flail chest, and possible intrathoracic injury help in making the decision for proper treatment plan.

CONCLUSION

After comprehensive review of the present study, it is concluded that:

- Blunt trauma, mainly road-side accidents formed the most common cause of chest injury, followed by assault and falls from height etc. and commonly affected victims are males of productive age.
- The majority of these patients can be managed by simple intervention i.e., intercostal drainage. Patient with multiple rib fracture can be managed by non invasive ventilation and only few require thoracotomy.
- The risk of mortality in chest trauma has been associated with the presence of more than two rib fractures, age older than 60 years and with associated head and abdominal injury.
- The ability to identify those patients having significantly higher risk for morbidity and mortality ensures the establishment of treatment priorities and efficient management of existing injuries.

ABSTRACT

Background: Necrotizing soft-tissue infections are infection of any of the layers within the soft tissue compartment that are associated with necrotizing changes. These infections are highly lethal if not diagnosed. The purpose of this article is to assess the different diagnostic tools.
Methods: We carried out a retrospective study to assess the prevalence of soft tissue infections at Geetanjali medical college and hospital, Udaipur (Tertiary care rural centre) in last four years. Clinical details of the 216 patients with soft tissue infection were recorded from their case sheets and were analyzed with reference to their age, sex, risk factor, symptoms, etiology, microbiology, treatment employed, complication and final outcome etc.
Results: Pain and swelling were commonest presenting symptoms found in every case. Diabetes and Trauma were major predisposing factor in our series. NSTI differ from NNSTI with respect to presence of blister (50% versus 5.8%), Dusky discoloration (58.3% versus 0%), Necrotic skin (51.04% versus 0%) and Crepitance (6.2% versus 0%). In present series' most common organism causing NSTI in our institute is gram negative bacilli .Prompt resuscitation followed by early and adequate debridement remains the cornerstone of management of NSTI.
Conclusions: Diagnosis of necrotizing infection is challenging but there are enough tools including clinical findings, biochemical parameters, imaging aids and invasive procedures that can help make the diagnosis. When in doubt, exploration of the compromised tissue should be performed. The mainstay of treatment is early and adequate surgical debridement.

Keywords: NSTI- Necrotizing soft-tissue infections, NNSTI - Non- Necrotizing soft-tissue infections, Debridement

INTRODUCTION

Necrotizing soft-tissue infections (NSTIs) are highly lethal infections. These infections were first described by Jones in 1871 and termed as "hospital gangrene".[1] Since then, multiple descriptions of NSTI have been published, and a wide number of terms, definitions, and classifications have been used.[2-5]

In 1951, Wilson coined the term "necrotizing fasciitis" to encompass some of these infections that is rapidly spreading and potentially devastating infection of the superficial and deep fascia with secondary necrosis of the overlying skin.[6]

The early diagnosis is main challenge in treating patients with NSTI, and knowledge of various clinical sign and laboratory markers can be helpful for distinguishing between cases of cellulitis, which should respond to

In present series' most common organism causing NSTI in our institute is gram negative bacilli followed by haemolytic streptococci. Most of the infection was polymicrobial in nature.

Table 5: Distribution of mode of treatment.

Management	No. of Pt.	% of Pt.
Multiple release incision and fasciotomy	26	27.08
Debridement	68	70.83
Amputation	2	2.08

In our series debridement was done in 70.8% of cases with in 8 hours of admission after initial resuscitation. Multiple release incision and fasciotomy was done in 22.9% of cases while amputation at mid-thigh level was done in 2 cases to save life of patient.

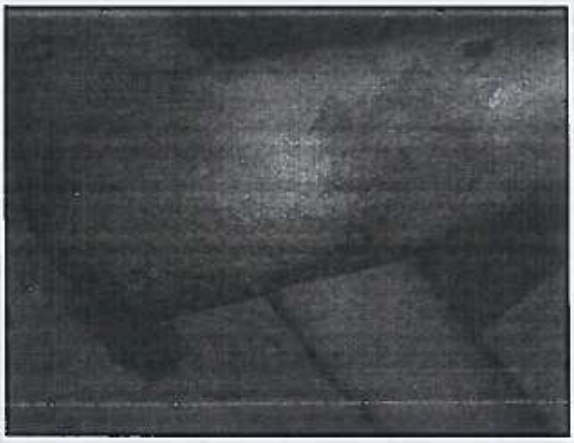

Figure 1: NSTI lower limb- showing blisters, dusky discoloration and skin necrosis.

Figure 2: NSTI lower limb showing blisters fiied with toxic fluid and pus, dusky discoloration and skin necrosis.

Figure 3: NSTI lower limb: debridement of necrotic tissue.

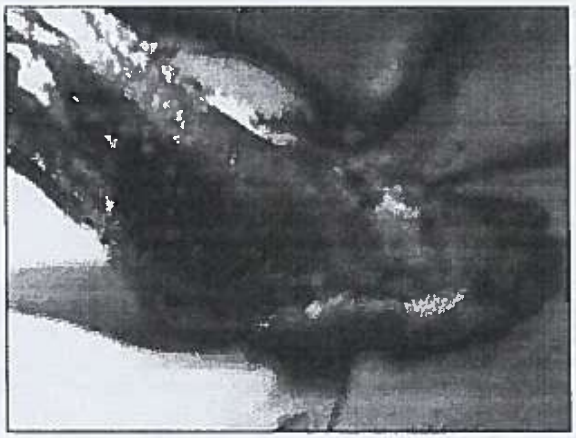

Figure 4: NSTI foot and lower leg; extensive necrosis of skin.

Figure 5: Figure NSTI foot and lower leg: extensive early and adequate debridement.

infected tissue that controls the source of infection and allows for future recovery. Broad-spectrum antimicrobial therapy should be started early to include coverage for gram-positive, gram-negative, and anaerobic organisms. Special consideration for group A *Streptococcus* and *Clostridium* species should be taken. Acceptable regimens include monotherapy agents, such as imipenem, meropenem, ertapenem, piperacillin/tazobactam, and tigecycline. Multidrug regimens have also been described, including triple-drug therapy regimens, such as high-dose penicillin, high-dose clindamycin, and a fluoroquinolone or an aminoglycoside for coverage of gram-negative organisms. Vancomycin, daptomycin, or linezolid should be included in the regimen until methicillin-resistant staphylococcal infection has been excluded. Antimicrobial administration should be continued until no further debridements are needed and the patient's physiology has improved.

Debridement of the necrotic tissue should be undertaken as soon as possible as it is probably the most important determinant of outcome in necrotizing soft tissue infections. This was well described in a study by Bilton, et al in which patients with necrotizing soft tissue infections who had adequate surgical debridement (early and complete) were compared to those with either delayed or incomplete debridements. The mortality in the latter group was 38% compared to 4.2% in the group receiving adequate surgical treatment.[14] During the operation, a generous incision is performed and if needed, the incision is extended to allow for complete debridement of the infected or necrotic tissue. Occasionally, amputation of a limb is necessary to achieve this goal to save life of patient. Healthy, viable, bleeding tissue should be present at the edges of the excision site, and aggressive resuscitation should accompany the perioperative period. Once the initial debridement has been done, management in an intensive care unit is recommended, and scheduled debridements at intervals of 6–48 h should be performed until no further necrosis or infected tissue is seen. Finally, physiologic support, combined with close monitoring in an intensive care unit is encouraged. It is not uncommon to see patients with NSTI develop organ failure, such as acute renal failure and acute respiratory distress syndrome, which require replacement therapies.

The most important discriminative information to be established in patients with soft-tissue infection is the presence of a necrotizing component. This will confirm NSTI, and by definition, will identify patients that require surgical debridement. The first and most important tool for early diagnosis of NSTI is to have a high index of suspicion. When in doubt, exploration of the compromised tissue should be performed. Intravenous drug user are found to be high-risk group for developing necrotizing soft tissue infections, and when evaluated for soft tissue infections they should undergo a thorough assessment that can confidently rule out a necrotizing infection. The mainstay of treatment is early and adequate surgical debridement with scheduled returns to the operating room. We have also observed that cases of NSTI without a recognized precipitating factor are more likely to be caused by group a streptococcal infection. More recently, NSTI without a recognized precipitating factor has also been identified with community-acquired methicillin-resistant staphylococcal infection.[14]

Since the first description by Jones, mortality in patients with NSTI remains high. He reported a mortality rate of 46%, and a recent pooled analysis determined it to be ~34%.[1,15] More recent series have reported mortality rates with a range of 16%, 24%, a rate that, although lower than the rate 100 years ago, still accounts for high mortality associated with NSTI. In our series mortality rate was 16.66 % .This low rate is related with early and adequate debridement within 8 hours of admission and aggressive critical care of these pt.

Bosshardt, et al published a series of patients with predominantly intravenous drug use-related necrotizing soft tissue infections over a 5-year period and showed that the incidence more than doubled when compared to the first years of the study.[20]

CONCLUSION

We also draw following conclusion. Pain and swelling were commonest presenting symptoms found in every case. Diabetes and Trauma were major predisposing factor in our series. NSTI differ from NNSTI with respect to presence of blister (50% versus 5.8%), Dusky discoloration (58.3 % versus 0%), Necrotic skin (51.04% versus 0%) and Crepitance (6.2% versus 0%). So Bullae, necrotic skin, dusky discoloration and crepitance are strongly predictive of NSTI. Four laboratory criteria that are strongly suggestive of NSTI ($P< 0.001$) i.e. statistically significant. Total Leucocytes Count more than 15 X 10 9/L. S. Creatinine more than 1.5 mg/dl.Serum Na+level less than 130 mmol/L. Presence of gas in x-ray of affected part. In present series' most common organism causing NSTI in our institute is gram negative bacilli followed by haemolytic streptococci. Most of the infection was polymicrobial in nature. Prompt resuscitation followed by early and adequate debridement remains the cornerstone of management of NSTI. Wound inspection after 24 hours to confirm the adequacy or to complete debridement. In conclusion of our study we would like to say that lack of awareness among clinician may play a major role in delay of diagnosis and institution of therapy that leads to subsequent high mortality and morbidity. The most important factor in survival in present series was related to rapidity of debridement within 8 hrs of admission after initial resuscitation. Utilizing these principal the morbidity and mortality of patients with NSTI should be substantially reduced.

ABSTRACT

Background: Peptic perforation is a life threatening complication of peptic ulcer disease requiring prompt surgical management. Omental patch repair with peritoneal lavage is the mainstay of treatment for perforated peptic ulcer at most of the centres. Laparoscopic repair has been described by various authors since 1990 in different part of world. In current study we have assessed the feasibility and safety of use of laparoscopy for this life threatening surgical emergency. The outcome were analyzed in terms of operating time, post-operative complications, medication, hospital stay, morbidity and mortality.
Methods: This study was carried out in period of two years from January 2012 to December 2013. Patients were initially assessed in emergency department and then after resuscitation taken up for surgery. Patients with provisional diagnosis of perforated peptic ulcer were included in the study, meeting inclusion criteria.
Results: Total 30 patients were studied out of total 38, who were operated in the study period. 26 males and 4 females, age ranged from 18-60 years, operative time was 55 to 110 minutes. In post-operative period the need for intravenous medication (analgesics and antibiotics) was less, early assumption of routine activity and early discharge. A very important factor noted that patient were psychologically so happy and convinced that they did not have big wound over abdomen and they can resume their routine activity as before.
Conclusions: Laparoscopic repair of perforated peptic ulcer is safe and effective in experienced hands in most of the patients. It offers all advantages of laparotomy without compromising the safety and outcome.

Keywords: Perforated peptic ulcer, Laparoscopy

INTRODUCTION

Peptic ulcer is a well-known disease widely prevalent in all socio economic strata all over world. The management of this common disease has evolved over a period of time. Current medical management with proton pump inhibitors and H.pylori eradications has drastically reduced the various complications and need of surgical interference. Still, peptic perforation is quite prevalent life threatening surgical emergency encountered in general surgical practice. Omental patch repair (modified Graham repair) with thorough peritoneal lavage is the mainstay of treatment at most of the centers.[1]

Laparoscopy has emerged as gold standard for surgical treatment of various diseases in last 2-3 decades due to it's certain advantages like less post-operative pain, less hospital stay, less wound complications, early return to normal activity etc.[2]

This study is aimed to assess the feasibility, safety and advantages of use of laparoscopy in the treatment of this

unchanged. Minimal access surgery has gained wide acceptance amongst surgeons and general public all over world due to its definitive advantages. Although there are still some constrains amongst conventional surgeons for the use of this technique in certain surgical emergencies.

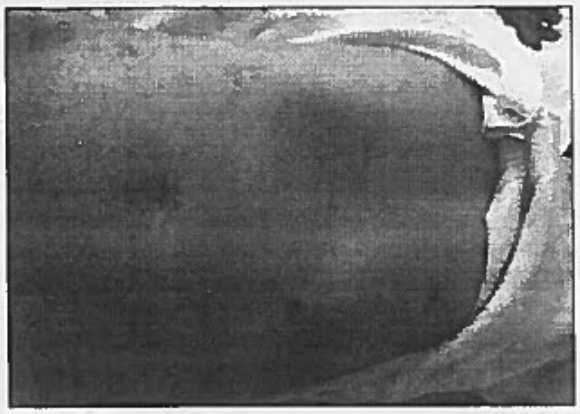

Figure 1: Post-operative photograph showing port position for laparoscopic peptic perforation repair.

In 1990 Mouret et al. reported the first laparoscopic sutureless fibrin glue omental patch for perforated duodenal ulcer repair.[5] The first successful laparoscopic suture repair for perforated peptic ulcer was described by Nathanson et al. in 1990.[6] Since then, many studies has been conducted by various authors in different part of world to define the use of laparoscopy in surgical management of perforated peptic ulcer. Costalat et al reported combined endoscopic and laparoscopic approach using ligamentum teres hepatis.[7] In 1993 Darzi et al, and Nassar et al in 1994 reported laparoscopic omental patch repair with use of automated stapler.[12,13] Siu WT et al described single stitch laparoscopic omental patch repair of perforated peptic ulcer in 1997.[3] Masao Matsuda et al from Japan also published an article suggesting that laparoscopic omental patch repair offers advantages of laparoscopic surgery and an attractive alternate to open surgery.[17]

After Mouret and Nathanson many authors worked in this field and described various techniques of perforated peptic ulcer closure i.e. simple suturing, by gelatin sponge and fibrin glue, stapled omental patch repair, gastroscopy assisted insertion of ligamentum teres hepatis to close the perforation, gastroscopic guided omental plugging to close the perforation.[22] single suture with omental patch repair.[3]

Studies were done to compare open versus laparoscopic repair.[16,19,20,23] Siu et al and found that laparoscopic repair was superior then open in terms of size of incision, requirement of post op analgesia, less hospital stay, early return of normal activity, less immediate and long term complications etc. although the operating time was more in laparoscopic group in some studies but can be reduced by adopting certain techniques and with more and more experience. Almost all study groups recommended proper selection of patients and demands surgeons having good laparoscopic suturing skills and experience.

In our study, after analyzing the results it was found that duration of surgery was between 55-110 minutes. Time taken was more in initial cases and in few more contaminated cases, after that the operating time was nearly same as we take in open surgery and even less in few cases. Post operatively patients needed round the clock Intravenous analgesics for 2-3 days, Ryles tube could be removed in 2-3 days except in two cases in which we had to keep ryles tube for 4 days which was badly contaminated large perforation of about 1cm. we have started oral feeding in 3-4 days in most of the cases except in 5 cases which were having large perforation with more peritoneal contamination. Hospital stay was 4-5 days in most of the cases; only 3 patients had 6 days stay. 2 patients had chest complications in immediate post op period which were managed comfortably in ICU and recovered in 2-3 days. There was no wound gap, no burst abdomen, no residual collection or pelvic abscess noted in any case. No incidence of any incisional hernia was noted in any case. Patients were allowed and encouraged to return to the normal activity after 7-10 days. No mortality was noted in our series.

CONCLUSION

The management of this common disease is evolved over a period of time. Current medical management has drastically reduced the various complications and need of surgical interference. Still peptic perforation is quite prevalent. Gold standard treatment is conventional laparotomy and omental patch repair (modified Graham repair). Laparoscopy has emerged as gold standard for surgical treatment of various diseases in last few decades. We conclude with the present study that laparoscopy is an effective tool in the surgical management of perforated peptic ulcer.

It requires experience and technical expertise in laparoscopic surgery. If proper selection of patients is done laparoscopic repair is safe and feasible. It does not increase the cost of treatment infact it helps in reducing the cost by less hospital stay, less medication required, less morbity, early return to normal activity and to workplace. We hereby recommend laparoscopic repair in selected patients as treatment of choice as it offers all the advantages of laparoscopy without increasing the risk. It is a safe, effective and cost effective method for the treatment of perforated peptic ulcer.

ABSTRACT:

Objectives: To evaluate the water soluble contrast radiography as diagnostic modality in small intestinal obstruction, where plain X-ray abdomen is inconclusive. **Material and method:** Study was conducted upon 20 patients admitted in the surgical department of Geetanjali Medical college and Hospital, with features of intestinal obstruction but no concrete evidence of the same and hence underwent contrast study with water soluble contrast agent. After admission a brief history, clinical assessment and plain abdominal radiograph were taken in the standing and supine position and in case of suspicion, there the water soluble contrast study was carried out. **Results:** Total 20 patients were taken for contrast study on the basis of X-ray findings. Out of these, 6 patients showed clear cut off in the contrast level in the small intestine and were taken for surgery. Two patients in which findings were equivocal were also subjected to surgery and were found to have the intestinal obstruction. In 12 patients, dye passed freely into large bowel, so these patients were managed conservatively. Out of these, 3 Patients didn't respond to conservative management and were subjected to surgery. Thus in 17 patients' correct diagnosis could be made with the help of contrast studies. **Conclusion:** To Conclude water soluble contrast study is safe and easy to perform, and gives useful information regarding presence or absence of complete obstruction and aids in the decision making regarding the mode of management.

Keywords: water soluble contrast radiography, intestinal obstruction, plain X-ray abdomen

INTRODUCTION

Intestinal obstruction is a condition which is seen commonly in surgical practice and is responsible for 20% admission in surgical emergency. (1) (2) Mortality rates for intestinal obstruction are declining, but still remain as high as 5-11 %(3) (4). Despite of advancements made in the

around 40 ml in children. The dye was introduced through the Ryle's tube and the tube occluded. For the next four hours aspiration was not done.

Supine abdominal radiograph in the AP position were taken at 30 minutes and again at four hours after administration of dye.

The cases with a clear cut off in the contrast level in the small bowel, or if the contrast failed to reach large bowel by 4 hrs, were taken up for surgery. Cases in which second film showed persistently dilated gut loop around a fixed part or were not conclusive were taken for surgery.

The other cases in which the contrast passed off into the colon by end of 4 hour were managed conservatively.

Exclusion Criteria

1. Patients with clinically obvious intestinal obstruction such as obstructed inguinal hernia.

2. Patients suspected to have intestinal strangulation.

3. Patients who underwent barium contrast-study in immediate past.

RESULTS:

Study was conducted upon 20 patients with features of intestinal obstruction but no concrete evidence of the same and hence underwent contrast study with water soluble contrast agent.

Patients with obvious cause of intestinal obstruction or in whom there was the strong doubt of strangulation, were excluded from study.

When X-ray showed contrast in large bowel in 4 hours, these patients were considered to have no obstruction and were managed conservatively. Patients in which the contrast failed to does not reach large bowel in 4 hrs, were operated.

There were 11 males and 9 females in the study. Maximum incidence of intestinal obstruction was in the age group 20- 29 years and 40-49 years.

Pain was the commonest symptom and distension of abdomen was the commonest sign. Dilated gut loops were the commonest findings in supine X-ray abdomen.

In 6 patients dye showed clear cut off and on surgery all had the cause of intestinal obstruction. 2 patients in which the findings were equivocal were operated.

In 12 patients dye passed freely into colon. Out of 12 patients, 9 patients recovered on conservative management and 3 patients required surgery.

The commonest cause of intestinal obstruction was adhesive obstruction and intestinal tuberculosis. Water soluble contrast study was helpful in 85 % of the patients with intestinal obstruction and the outcome could be correctly predicted.

There was no side-effect noticed due to contrast agent. Mortality rate, observed in the study was 10 %.

correct and timely diagnosis for proper management to save his life.

In the present study, 50 % of the patients were seen in the less than 40 years of age group. Jean-Jacques Duron J.J. et al found that age of less than 40 years was a risk factor for the small intestine obstruction. The reason that less patient was seen in the age group of < 40 yrs may be due to the presence of Kalawati Saran children hospital in near vicinity. (8)

Sarr et al (1983) found a male: female ratio of 1.14: 1. (9)In the present study male: female ratio 1.2: 1. The degree of male predominance in our study is consistent with the previous studies.

Out of the cardinal features of intestinal obstruction i.e. pain, vomiting, distension and obstipation, all four were not present in all patients of intestinal obstruction, but were present in the varying combination each patient.

La Pass et al too found that patients commonest complaint were either crampy abdominal pain or vomiting and abdominal distension along with high pitched bowel sound were commonest physical findings. (10) Similar conclusion was derived in our study. The high incidence of abdominal pain could be due to the fact that it is the pain that makes the patients aware of their problem and brings them to the hospital.

Plain X-ray was done in the patients suspected of obstruction. Maglinte DD reported in their series that plain X-ray abdomen was diagnostic in 60% of cases. (11) Our present study diagnostic accuracy of plain X-ray abdomen was 60 %, which is same with literature.

In the present study, dye passed freely into colon in 12 patients. Out of these 12, 3 patients required surgery as their obstruction didn't relieved on conservative management. One of these patients refused surgery, one patient had the band as the cause of obstruction, one patient had appendicular perforation with flimsy adhesion. So the surgery could be avoided in 45% of the patients. Hok-Kwok Choi (2002) performed contrast study in nineteen patients. The use of Gastrografin significantly reduced the need for surgery by 74%. (12) Joyce et al managed 112 patients out of 127 patients without surgery on the basis of the water soluble contrast study. (13)

In the contrast study, when there was clear cut off, patients were considered to have complete obstruction, therefore subjected to surgery. Joyce et al operated on 15 patients out of 127 patients based on water soluble contrast radiography, as study showed clear cut off of the contrast level.(13) Dunn et al in their study of 327 patients, performed surgery in 42 patients, based on contrast study.(14)

They found causes as multiple adhesion, single obstructing band, intussusceptions, etc. In the present study 6 cases showed clear cut off in the contrast level and underwent surgery. All of them had intestinal obstruction proved on laparotomy.

When the contrast radiology does not fulfil the criteria of either obstruction or free passage, the surgeon is obliged to perform an operative procedure in order to make a diagnosis.

In the present study two patients, who had equivocal finding, were operated. One of them had pyloric stenosis with Para duodenal

ABSTRACT

Background: Bladder cancer, a lethal disease accounts for 3% of cancer deaths. With possibility of various urinary diversion options after bladder removal having comparable cancer control and complications, quality of life becomes an important factor in deciding the type of urinary diversion.

Methods: Retrospective observational study with statistically appropriate sample size of 50. Patients of radical cystectomy and ileal conduit given validated Functional Assessment Of Chronic Illness Therapy for Bladder Cancer (FACT-BI) Questionnaire to answer about post-operative quality of life in terms of five parameters i.e., physical, mental, social, emotional and cancer specific well-being after 1 year of surgery.

Results: Results analysed by FACIT-BI questionnaire analysis methods statistically, in terms of total scores and sub-scores. In our study the mean scores of physical well-being (PWB) subscale is 24.08±4.67 (range 0-28), social well-being (SWB) subscale is 23.52±4.35 (range 0-28) , emotional well-being (EWB) subscale is 20.06±5.09, functional well-being (FWB) subscale is 21.84±6.01 (range 0-28), bladder cancer subscale is 36.44±5.72 (range 0-48). While mean trial outcome index score is 82.16±3.5 (range 0-104), FACT- General (G) score is 89.50± 15.88 and mean FACT-BI total score is 125.94±19.04.These scores provides the quantitative assessment of the quality of life and higher scores indicates better quality of life.

Conclusions: Assessing quality of life for a particular type of urinary diversion, with questionnaires, gives surgeons and patients, guidance regarding diversion of choice.

Keywords: Bladder cancer, Radical cystectomy, Ileal conduit, Quality of life, Questionnaire

INTRODUCTION

Bladder cancer is a lethal disease which accounts for 3% of all cancer deaths. In 2010 there were estimated 70,530 new cases of bladder cancer in the United States, and over 500,000 current survivors.[1] The standard of care for muscle-invasive bladder cancer is radical cystoprostatectomy in men and anterior exenteration in women.

Options for urinary diversion after cystectomy include noncontinent conduits, continent cutaneous diversions, and orthotopic bladder substitutes have been shown to have similar perioperative complication rates, cancer control, and morbidity.[2,3]

For >30 years, the ileal conduit (IC) has been considered the "standard" urinary diversion for bladder cancer patients undergoing radical cystectomy.

which may be attributed to old age and other co-morbidities.

94% patient did not have any nausea while 6% patient had occasional nausea that is unrelated to the disease. Over 64% of the patients had 'no problems' in meeting the needs of their family and another 22% were also able to' fulfil family needs' without major problem. Only three patients because of their physical condition found it difficult to fulfil their family needs.

90% of the patients 'did not have any pain' while 10% patients felt 'some pain' at stoma and wound site.

The treatment is in the form of radical cystectomy so most (90%) of patients are 'not bothered with side effects of treatment' as seen in other modalities like chemotherapy and radiotherapy.

...e 'feeling of illness' was not there in 88% of patients ...ile one patient (2%) felt 'too ill'.

Only two patients in our study were forced to spend time in the bed because of their physical weakness, old age and disease while 76% cases were performing their normal physical activities.

The mean physical well-being (PWB) subscale score in our study is 24.08±4.67 (range 0-28).

Social/family well-being

In this study, data reveals that 76% patients felt closeness to their friends and 86% cases got a lot of emotional support from their families. None of them said that they were not supported by their families.

94% of patients said that their families have 'completely accepted' their illness and 88.3% felt closeness to their ...tner and they were 'fully satisfied with their family ...ommunication' about the disease. Regarding the question about satisfaction with sex life only 16 out of 50 patients answered their question. Only two patients seem to be 'satisfied' with their sex life while 9 patients were 'not at all' satisfied. The mean social/family well-being (SWB) subscale score of this study is 23.52±4.35 (range 0-28).

Emotional well-being

In our study majority of the patients were 'not sad' (84%) while only 2% were 'very sad' because of the disease. 76% patients were 'very much' satisfied with the way they were coping with their illness and 86% were fighting with the disease with 'high hopes'.

90% of the patients were 'not nervous' and were not worried about dying. 84% of the patients were not worried that 'their condition will get worse'.

The mean emotional well-being (EWB) subscale score in our study is 20.06±5.09.

Functional well being

82% of our patients were able to do work 'normally' while 10% patient were not able to work because of the disease, old age and effects of the surgery and while for majority of them (80%) work was 'fulfilling'.

74% of the patients were able to enjoy their life nicely and 'enjoy the things they usually do for fun'. 88% of the patients said, that they have 'accepted their illness fully'.

Majority of the patients (70%) were 'fully content with the quality of life right now' while 6% patients are not content with the quality of life because of their physical, mental and emotional factors.

The mean functional well-being (FWB) subscale score in our study is 21.84±6.01 (range 0-28).

Additional concerns for bladder cancer subscale

This subscale is specific for bladder cancer patients and assesses problems related specifically for bladder cancer. This includes 12 questions of which two are specific for patients with ostomy appliance and one question regarding erection is specific to men.

As our patients were with ileal conduit, so they had no issues regarding the control of their urine.

62% of the cases said that they have 'not lost the weight' while 26% said that they have lost it a 'little bit', 4% patients said that they have lost their weight 'very much', which may be because of the decrease in appetite or progression of the disease.

Control of the bowels and frequency of urination are the concerns mainly for the MAINZ type of diversion and for the neo bladder group so in our study 99.9% cases replied to have normal urine output. Although five patients said they had diarrhoea but the cause should not be attributed to the surgery.

In our study 74% of the patients had a 'very good' appetite and another 18% had adequate appetite.

Most of the patients were happy with the 'appearance of their body' which is related to the presence of urinary stoma on anterior abdominal wall.

53.1% patients have marked the response '4' i.e., very much and 40.8% patients have marked response '3' i.e., quite a bit. None of the patient was completely dissatisfied with their body appearance.

74% patients had no embarrassment with their stoma attributable to psychological counselling.

Skin preparation for the prevention of surgical site infection: Efficacy of sodium fusidate and ethanol spray over conventional methods

Dr. Vikas Gupta, Dr. Sanjeev Kumar and Dr. KC Vyas

DOI: https://doi.org/10.33545/surgery.2019.v3.i4b.221

Abstract
Surgical site infection is an overwhelming menace for the surgeon and it increases the morbidity and mortality of the patient, increases the hospital stay and cost of the treatment. One of the important factors among these is the preoperative preparation of the skin with antiseptic agent. For centuries there has been a search for an ideal agent for this purpose. This study was undertaken to evaluate the newly introduced Sodium fusidate and Ethanol spray as a preoperative skin preparation agent and compared it with other conventional methods. This prospective study was conducted at Maharana Bhupal Government Hospital, Udaipur in the general surgical wards on 178 patients during the period of March 2009 to August 2010. It included all the clean and clean contaminated intra-abdominal surgical procedures conducted in planned surgery. In the present study, we observed wound sepsis in 24 cases out of a total of 178 cases. Postoperative wound sepsis rates were higher in clean contaminated wounds(16.52%) as compared to clean wounds(7.9%). Maximum infection rate was present in Savlon and Spirit group (14.28%), while it was least in Fusidic acid spray group (5.88%). The most common organism isolated from infected wound was *Staphylococcus aureus* (41.67%), followed by *E. coli* (20.83%) and *Streptococci* (16.67%). Sodium fusidate and Ethanol spray is an effective skin preparation agent as concluded by our study in clean and clean contaminated elective abdominal procedures.

Keywords: Surgical Site Infections (SSIs), sodium Fusidate and ethanol spray, conventional methods, abdominal procedures

Introduction
Surgical site infection (SSI) and post-operative wound sepsis is a serious problem and it continues to be a significant problem for surgeons in the modern era. Their spectrum of effect on individual's health ranges from slightest of inconvenience to major deleterious health effects and even death. The burden of high rates of surgical wound infection in terms of economics is also tremendous [1]. The financial drain that these infections place on the resource constrained hospitals in the form of prolonged hospitalization along with increased duration, dosage of medication, dressings and more intensive nursing care are like the proverb 'Last Straw Broke The Camel's Back'.

For almost a century, there has been a continuing search for an antiseptic agent capable of sterilizing skin prior to surgical operation. But it is not possible to sterilize the skin; skin antiseptic aims to reduce the number of viable resident flora on or in the skin and to destroy pathogenic organism that may be on the skin as transients. By definition preoperative skin preparation is a safe, fast acting, broad spectrum, antimicrobial containing preparation that significantly reduces the number of microorganisms on intact skin.

Several antiseptic agents are available for preoperative preparation of the skin at the incision site. These include Iodophores (e.g., Povidone iodine), alcohol containing products, mercurochrome, Cetrimide and chlorhexidine Gluconate [2]. It is beneficial to use the combination that contain two different antiseptics with two different mechanism of killing action to have an additive antiseptic effect and kill microorganism more effectively, that is critical [3-6].

Recently a newer Microbicidal agent Sodium Fusidate spray 2% with 60% ethanol has been introduced. This exerts antibacterial activity by inhibition of protein synthesis by inhibiting the translocation enzyme by interfering with the binding of amino acyl transfer ribonucleic acid to ribosomes. This is produced by the fungus *Fusidium coccineum*.

his study majority of the preoperative cultures were sterile, in positive cultures *Staphylococcus epidermis* was the most mon isolate followed by *Staphylococcus aureus*. The most common organism isolated from infected wound was *Staphylococcus aureus* followed by *Escherichia coli* and *Streptococci* as shown in Table 2.

Table 3: Wound sepsis rates with various agents in Clean and Clean contaminated surgeries

No.	Agent	Clean surgeries		Clean contaminated surgeries	
		No. of infected cases	Total no. of cases (%)	No. of infected cases	Total no. of cases (%)
1	Sodium Fusidate and Ethanol Spray	1	17 (5.88)	7	43 (16.28)
2	Povidone-Iodine	2	24 (8.33)	6	36 (16.66)
3	P-I & Metronidazole	1	15 (6.67)	3	23 (13.04)
4	Savlon & Spirit	1	7 (14.28)	3	13 (23.07)
5	Total	5	63 (7.9)	19	115 (16.52)

this study overall rate of infection in clean abdominal geries was 7.9%. Maximum infection rate was present in on and spirit group (14.28%), while it was least in Fusidic l spray group (5.88%). Overall wound sepsis rate in clean taminated abdominal surgeries was 16.52%. Maximum rate present in savlon & spirit group (23.07%), minimum in P-I metronidazole group (13.04%), while it was 16.28% in idic acid spray group as shown in Table 3.

uis[illegible]dy local reaction in the form of irritation, sneezing and g[illegible] were present with the use of Fusidic acid spray in 5% of cases while one patient developed mild erythema in P-metronidazole group. None of the patient developed any emic adverse effect.

cussion

his study male constituted 68.23% and females comprised remaining 38.76% of the study population. This distribution the patient population favouring males can probably be buted to two reasons; sex ratio of the population favors es and attendants were more readily agreeable for surgical rvention for male patients in this mainly tribal belt.

ing the period of this study, a wide range of abdominal gical procedures were performed on 178 patients who were uded in this study. The most commonly performed surgery inguinal hernioplasty (26.4%) and urologic procedures 4%).

operative follow up of the patients in this study showed that 8% developed postoperative surgical site infection. This [illegible]epsis rate of the present study is very high as compared [illegible] reported by Byrne [11] (4.1%), Cruse and Ford [10]), Mead [12] (2.8%) and Olson [13] (4.2%). The difference is stically highly significant ($P< 0.001$) and can be partially ained on the following reasons:

Poor nutritional status of the patient included in this study compared to the western studies.

Lack of facilities in the resource strapped government hospitals compared to western health care system.

Tendency of late discharge of patients from hospitals to provide adequate postoperative care and rest to patients who were mostly labourers and residents of rural interiors with minimal access to health care facilities.

Poor socio-economic status and the lack of health insurance coverage for the masses, limit the use of disposable and the latest technology, which carries a prohibitive price tag with it.

studying the rate of postoperative wound sepsis across the groups, our findings are essentially similar to the other rnational studies [12, 13]. On evaluating the distribution of operative wound sepsis across the wound class, clean-aminated wounds were associated with a higher rate of wound sepsis (16.52%) as compared to clean wounds (7.9%). The rates were significantly higher as compared to other international studies [12-14].

In the clean abdominal surgeries minimal wound sepsis rate was present in the in whom surgical site was prepared with Fusidic acid spray (5.88%). This may be explained due to the fact that Fusidic acid has high activity against *Staph. Aureus* [7] which is the most common isolate is clean surgical wounds. Spray form of application also helps in deeper and faster penetration of tissues and better efficacy. Maximum wound infection was seen when skin preparation was done only with Savlon and Spirit (14.28%). The infection rates in all groups when compared statistically was not significant (p=0.14).

In the clean contaminated abdominal surgical procedures least SSI rate (13.04%) was seen with Povidone-Iodine and metronidazole group. This can be explained by the fact that in clean contaminated surgeries the source of infection is mostly endogenous from the genito-urinary or alimentary tract as described by Hojer [15] and Cruse and Ford [16]. This combination covers the spectrum of activity against the causative pathogens. Maximum rate of infection was again seen with Savlon & Spirit group (23.07%) while the Fusidic acid spray group had the SSI rate of 16.28%. When analyzed statistically the difference was statistically non-significant among all groups (p=0.295).

In our study preoperative incision site culture swab showed sterile culture in 69.66% of cases, this may be explained due to soap and water scrub given to the patient and administration of preoperative antibiotics. In 17.97% of the cases *Staphylococcus epidermidis* was isolated while *Staphylococcus aureus* was isolated in 9.55% of cases.

Postoperative culture from infected wound showed *Staphylococcus aureus* to be the most common pathogen isolated from 41.67% of cases followed by E.coli in 20.83% cases and Streptococci in 16.67% cases. Hojer [15] studied that in clean operations exogenous *Staph. aureus* is the usual cause of infection. Curse and Ford [16] demonstrated that the most common isolate from class I wound was *Staph. aureus* followed by *Enterococci* and *Pseudomonas*. Class II wounds were most frequently infected by *Enterococci* then *Pseudomonas* and *Staph. aureus*. Haley *et al* [17] similarly showed that *Staphylococcus* was the most common pathogen, of these *CoNS* (*Coagulase negative Staphylocci*) accounted 18.9% of the isolates and *CoNS* were isolated in about 13.6%. Second most common offender was *Enterococcus* species at 13.6% of the isolates. Close on their heel were *E.coli* 8% and *Pseudomonas aeruginosa* 7.8%. Nichols [18], in his study showed that since 1984, *Staph. epidermidis* has been one of the three most frequently cultured wound infection pathogens, other two being *Staph. aureus* and *Pseudomonas*. Weiss *et al*. [19] described various pathogens isolated from postoperative SSI. *CoNS* were most common 25.6% followed by Enterococcus 11.5%, Staph

Role of Diagnostic Laparoscopy in chronic Abdominal Pain

Bhavin Baria[1], Kamlesh Gohil[2*], Siddharth Kumar[3]

[1]Assistant Professor. [2,3]3rd year resident doctor, department of surgery civil Hospital Ahmadabad

ABSTRACT

BACKGROUND: Chronic Abdominal Pain is a common problem in hospital. Many patients presenting with chronic Abdominal Pain had no specific etiological diagnosis at end of their Diagnostic workup.with introduction of laproscopic surgery,a new tool has been added to our knowledge. Laparoscopy can identify abnormal finding and improve of patients with chronic pain. **MATERIAL AND METHODS:** A total number of 50 randomly selected patients withchronic Abdominal Pain were enrolled in the prospective cross sectional study.after laproscopic post operative outcome was analyzed. **RESULT:** We found in a selected patient group, laparoscopic evaluation of chronic Abdominal Pain is usually associated with a positive outcome in term of less or no pain after two months of Laparoscopy.

Key Words: Laparoscopy, Chronic Abdominal Pain, Postoperative evaluation

INTRODUCTION

Chronic abdominal pain is a common disorder both in general practice and in hospitals. Although patients with this type of pain may have undergone numerous diagnostic workups, including surgery, their pain remains a challenge to all known diagnostic and treatment methods. After all, more than 40% of patients presenting with chronic abdominal pain had no specific etiological diagnosis at the end of their diagnostic workup.[6-9] Chronic abdominal pain is associated with poor quality of life[10] and significant levels of depressive symptoms.[11] Much is about the prevalence and suffering associated with chronic abdominal pain.[6] Many common organic and functional diseases can cause it. The most common organic conditions include intestinal adhesions,[11,12] appendicular causes,[16] and biliary causes,[14,15] while functional conditions include irritable bowel disease,[17] functional dyspepsia,[18] and various motility disorders.[19] Abdominal wall pain is also common and frequently mistaken for visceral pail-.02°'21) After ruling out common diseases by careful investigations, many patients are still undiagnosed and represent a major diagnostic challenge to the surgeon.[22] With the introduction of laparoscopic surgery, a new tool has been added to our knowledge. The use of this new technology in the diagnosis and management of chronic abdominal pain has been tried in previous studies. Laparoscopy can identify abnormal findings and improve the outcome in majority of patients with chronic abdominal pain, as it allows surgeons to see and treat many abdominal conditions that cannot be diagnosed otherwise. It is a safe and effective tool and can establish the etiology and allows for appropriate interventions in such cases. Abdominal adhesions are the most likely findings, especially in patients with past history of abdominal operations. Other findings such as appendicular pathology, hepatobiliary causes, and endometriosis can be discovered and dealt with.[23] However the role of laparoscopy in chronic abdominal pain is still debated by some authors who do not recommend it as a treatment for adhesions in patients with chronic abdominal pain. In the present study we

relief. All the patients were re-evaluated after two months. The pain in the late postoperative period was classified into: worse, unchanged, less pain, and disappearance of pain. Less pain and disappearance of pain were referred to as positive outcomes, while unchanged and worse pains were referred to as negative outcomes.

Statistical analysis: Gathered data were processed and analyzed.

RESULTS

The studied patients were in the age group ranging from 13 — 55 years. Most of the patients studied were females (84%). The mean duration of pain was seven months with the range of duration from three to eleven months. The most common site of pain was the right lower quadrant (50%) followed by the periumbilical region (40%). Twenty patients were using either non-steroidal drugs or pain killers to relieve the pain, and six patients were using proton pump inhibitors. Eleven patients (22%) had undergone at least one previous surgical abdominal procedure.

Table 1: Baseline Characteristics of the Studied Patients

Characters	Value
Age(years range)	13-55
Gender	
Male 8 (16%)	
Female 42 (84%)	
Duration of Pain (months) Mean (range)	7 (3-11)
Site of Pain	
Right Lower Quadrant	25 (50%)
Right Upper Quadrant	4 (8%)
Left Lower Quadrant	1 (2%)
Left Upper Quadrant	Nill
Periumbilical	20 (40%)
History of Previous Abdominal Surgery	11 (22%)

There were eight cases converted to open procedures. Out the 50 patients with chronic abdominal pain. a definitive diagnosis was established in 45 patients (90%), while no identifiable cause could be reached in five patients (10%). The most common laparoscopic findings were appendiceal pathology (40.7%). Other findings included ovarian cysts (16.7%), adhesions (14.8%), gall bladder pathology (7.4%), terminal ileitis (7.4%), mesenteric lymphadenopathy (5.6%), strictures (5.6%) and jejunal diverticulum (1.8%). Twenty-two patients showed appendiceal pathology: and their pathology revealed evidence of chronic appendicitis. All patients with adhesions had undergone previous abdominal surgery. Other pathological diagnoses such as chronic acalculus cholecystitis, and multiple enlarged mesenteric lymph nodes were found.

Table 2: Laparoscopic Findings, Intraoperative Data & Postoperative Characteristics

Findings	Value
Laproscopic Findings	
Abnormal Appendix	40.7%
Ovarian Cysts	16.7%
Adhesions	14.8%
Abnormal Gall Bladder	7.4%
Terminal Ileitis	7.4%
Enlarged Lymph Nodes	5.6%
Bowel Strictures	5.6%
Jejunal Diverticulum	1.8%
Postoperative Complications	
None	94%
Infection	6%
Postoperative Hospital Stay (Days Range)	2-14

Laproscopic management included appendectomy, adhesiolysis, cholecystectomy, ovarian cyst derrofing and cystectomy and lymph node biopsy. Five patients had no interventions performed. Postoperative hospital stay ranged from two to fourteen days. In most cases no postoperative complications had been reported except in three cases (showed infection). The wound infection responded well to oral antibiotic and daily dressing. During the time of follow up, all patients were re-evaluated for pain. After two months, positive outcome (less pain or disappearance of pain) was achieved in 47 patients (94%) while negative outcome (unchanged or worse pain) was noted in 3 patients (6%) in the first two months.

Table 3: Postoperative Pain Relief

Duration	Positive Outcome	Negative Outcome
After 2 months	94%	6%

DISCUSSION

Chronic idiopathic pain syndromes are among the most challenging and demanding conditions to treat across the whole age spectrum. Potentially it can be unrewarding for both the patients and the medical team.[24] Studies conducted with large community samples or hospital populations imply chronic abdominal pain is a pervasive problem. Abdominal pain was the third most common pain complaint of individuals enrolled in a large

ABSTRACT

Background: Diabetic foot is a frequent complication involving the foot of diabetic patient. Diabetic foot poses a significant health problem. It is rather an endemic disease today. Complications involving the foot cause significant pain and suffering, loss of productive time, hospitalization, heavy expenses to the patient, community and nation as well. To add to above vascular insufficiency and neuropathy accompanying the diabetic foot most often necessitate amputation of the limb. Advances in treatment of diabetes have caused increase in life span of diabetic patient which has resulted in an increase in complications of Diabetes Mellitus like vasculopathy, neuropathy and nephropathy. This in return has increased the prevalence and incidence of diabetic foot. Material and methods: This is the prospective study of 100 patienrs of diabetic foot during duration of about 2 years. Study group of newly diagnosed cases of Diabetis mellitus with foot lesions requiring surgical care was made. Over a period of 2 ½ years we studied 100 patients of diabetes mellitus with following aims and objectives: To identify the importance of foot care and footwear modifications in the form of pressure offloading, To identify and study effects of pressure offloading in duration of healing and salvaging the limb in a patient of diabetic foot, To compare results in patients of diabetic foot treated with pressure offloading and without pressure offloading, To analyze the results of study and reach a consensus regarding a practical and ideal plan of management for cases of diabetic foot. Results: In our study age varied from 25 years to 85 years. The highest incidence was in age group of 46 to 65 years (57%). Majority of patients were of type 2 i.e. non insulin dependent diabetes. Majority of patients presented with gangrene (25%) or non healing wound (33%) on foot. 62% of patients with offloading got healed completely within 10 weeks. Conclusion: Offloading application in patients with diabetic foot ulcer decreases the time period for complete healing of ulcers and decreases rate of complications.

Introduction

Diabetic foot is a frequent complication involving the foot of diabetic patient.[1] It involves a spectrum from superficial ulceration to complete gangrene of foot. India presently has about 45 million patients of diabetes mellitus.[2] Diabetic foot poses a significant health problem. It is rather an endemic disease today. Complications involving the foot cause significant pain and suffering, loss of productive time, hospitalization, heavy expenses to the patient, community and nation as well. To add to above vascular insufficiency and neuropathy accompanying the diabetic foot most often necessitate amputation of the limb.[3] In INDIA habits like walking barefooted, lack of knowledge regarding diabetic foot, hot climate leading to increased perspiration, poor hygiene, poor sanitation, diet poor in proteins, general poverty, lack of basic medical infrastructure, etc have worsened the problem. Neglect from medical and surgical faculty due to lack of glamour associated with this field has added to the problem statement. Over the years the life expectancy of diabetic patients with gangrene of foot has not changed much. Advances in treatment of diabetes have caused increase in life span of diabetic patient which has resulted in an increase in complications of Diabetes Mellitus like vasculopathy, neuropathy and nephropathy. This in return has increased the prevalence and incidence of diabetic foot. With the above considerations we undertook the study of 100 patients of diabetic foot admitted in our institute over a period of 2yrs and 6 months. An emphasis was laid on determination of peripheral neurological status and to study in detail the risk factors responsible for late healing and amputation. Aims and objectives:

Over a period of 2 ½ years we studied 100 patients of diabetes mellitus with following aims and objectives.

1] To identify the importance of foot care and footwear modifications in the form of pressure offloading.
2] To identify and study effects of pressure offloading in duration of healing and salvaging the limb in a patient of diabetic foot.
3] To compare results in patients of diabetic foot treated with pressure offloading and without pressure offloading.
4] To analyze the results of study and reach a consensus regarding a practical and ideal plan of management for cases of diabetic foot.

Material and methods

This is the prospective study of 100 patienrs of diabetic foot during duration of about 2 years. Study group of newly diagnosed cases of Diabetis mellitus with foot lesions requiring surgical care was made. Informed and written consent were taken from all the patients before including them into study.Clinical history & findings were be noted. Necessary investigations were carried out. Comparison of healing time was done between patients who have been treated with and without offloads

Inclusion criteria:

1] New and known cases of diabetes mellitus.
2] Wound / ulcer / gangrene of feet due to diabetes.

Exclusion criteria:

1] Seriously ill patient who required intensive care unit monitoring.
2] Wound / ulcer / gangrene of feet due to diseases other than diabetes.

Half of the patients were given offloading as the form of total contact casting and rest half were not given offloading in the form of total contact casting. Patients were counselled for foot care and need for regular follow up on discharge.

decreases the time period for complete healing of ulcers and decreases rate of complications.[12]

A Prospective Study on Prevalence and Percentage of Undiagnosed Type 2 Diabetics Patients Undergoing Elective Surgery

Mohammed Ashraf Khan

**Assistant Professor, Department of General Surgery,
Ananta Institute of Medical Sciences and Research Centre, Rajsamand, Rajasthan, India.**

ABSTRACT

Introduction: The major form of diabetes mellitus is Type 2 diabetes. It accounts for 90 percent of the diabetic population. Patients with diabetes mellitus (DM) are prone to adverse outcomes. It is observed that one fifth of the patients undergoing surgery are diabetic.

Methodology: This study was conducted in the Department of Surgery in the Department of General Surgery, Ananta Institute of Medical Sciences and Research Centre, Rajsamand. 289 total numbers of cases were included in this study. Each case has Type 2 DM.

Results: In our study, 289 total numbers of cases were included. Among the 289 cases 53.9% were male & 46.1% were female. Incidence of Diabetic Mellitus in undiagnosed & diagnosed cases was found 41.5% & 58.5% respectively.

Conclusion: This study concludes that there is a strong need of awareness about diabetes and early diagnosis of diabetes to reduce its various complications.

Keywords: Diabetes Mellitus, Metabolic Disorder, Undiagnosed Cases, Diagnosed Cases.

INTRODUCTION

Diabetes mellitus (DM) is a metabolic disorder. It results from a defect in insulin secretion or insulin action.[1-4] It was estimated that worldwide, more than 200 million people had DM in 2010, and 300 million will subsequently have the disease by 2025.[5-7] it has been reported that India had 32 million diabetic subjects in 2000 and by the year 2030, it will be 80 million.[8] The incidence of diabetes is rising all over the world at an alarming rate.[9] India is termed as the "Diabetes capital of the world", due to the highest number of diabetic patients in the world. The major form of diabetes mellitus is Type 2 diabetes. It accounts for 90 percent of the diabetic population. Patients with diabetes mellitus (DM) are prone to adverse outcomes.[10,11] it is observed that one fifth of the patients undergoing surgery are diabetic. However, several treatment strategies are employed to get rid of it globally. But in developing countries where resources are limited, needs to be reviewed. Over the past thirty years, the status of diabetes has changed from mild disorder to one of the major causes of morbidity and mortality.[8] It has been reported that there is a difference in percentage of urban-rural prevalence in type 2 DM in all parts of the globe including India. Hence, due to alarming rate of diabetes it was necessary to study the incidence of prevalence and percentage of undiagnosed type 2 diabetics admitted for elective surgery.

MATERIALS & METHODS

Study Area

This study was conducted in the Department of General Surgery, Ananta Institute of Medical Sciences and Research Centre, Rajsamand, Rajasthan, India.

Study Population

289 total numbers of cases were included in this study. Each case has Type 2 DM.

Study Duration

The duration of study was over a period of 2 year.

Data Collection

On enrolling the patients, routine investigation of fasting, random and post prandial blood glucose profile was done twice for confirmation by employing the glucose oxidation test for estimation of blood glucose.

The history and duration of diabetes in addition to epidemiological characteristic profile was noted. After being educated on diet, importance of insulin with special emphasis on need to adhere to treatment, the patients were allocated to different treatment groups for metabolic control.

Data Analysis

Data were analyzed by using Microsoft excel.

INTRODUCTION

Postoperative wound infections are one of the major preventable problem. It plays an important role in morbidity, mortality. It also affects the health care costs.[1] on the basis of depth of infection, it can be classified into three types: superficial incisional, deep incisional and organ/space. The symptoms of infection should be presented within 30 days postoperative.[2] Prevention of surgical site infection is primary consideration throughout the whole phases of surgery.[3,4]

In the advancement of surgery, post-operative wound infection has been the greatest obstacle from down the centuries. For safe surgery, Lister introduced antiseptic methods. The initiation of antibiotics did raise the hope of a permanent solution to post-operative infection but later it has become the nightmare of the surgeon. Though, many considered antibiotic could cover their lapses in surgical technique and asepsis. Extensive and often indiscriminate use of antibiotics led to development of resistance by various organisms and resulting the problem of hospital infection.[5] it has been reported that the administration of antibacterial agents within three hours after contamination of wound, it has no influence on the infection rate of the operative wounds. Infection can be adequately prevented, if the body already has adequate antibiotic concentration at the time of contamination.[6]

INTRODUCTION

Postoperative wound infections are one of the major preventable problem, it plays an important role in morbidity, mortality. It also affects the health care costs,[1] on the basis of depth of infection, it can be classified into three types: superficial incisional, deep incisional and organ/space. The symptoms of infection should be presented within 30 days postoperative.[2] Prevention of surgical site infection is primary consideration throughout the whole phases of surgery.[3,4]

In the advancement of surgery, post-operative wound infection has been the greatest obstacle from down the centuries. For safe surgery, Lister introduced antiseptic methods. The initiation of antibiotics did raise the hope of a permanent solution to post-operative infection but later it has become the nightmare of the surgeon. Though, many considered antibiotic could cover their lapses in surgical technique and asepsis. Extensive and often indiscriminate use of antibiotics led to development of resistance by various organisms and resulting the problem of hospital infection.[5] It has been reported that the administration of antibacterial agents within three hours after contamination of wound, it has no influence on the infection rate of the operative wounds. Infection can be adequate y prevented, if the body already has adequate antibiotic concentration at the time of contamination.[6]

Source of Support: Nil. **Conflict of Interest:** None

The concept of pre-operative antibiotic was introduced by Stranchan in 1977. He compared a single preoperative dose of Cefazolin with a regime of Cefazolin given for a period of 5 days post operatively. It has been observed that the infection rate seen in single dose was 3% and in multiple postoperative dose was 5%.[7] Prophylactic antibiotic therapy is clearly more effective where began preoperatively and continued through the intra operative period, with the aim of achieving therapeutic blood levels throughout the operative period.[8] In this study, the main emphasize on the risk factors that increase the SSI and role of prophylactic antibiotic administration to clean surgical cases in this institution.

METHODS

Study Population:- Two groups were included in this study. Each group had 200 cases.

Study Area:- This study conducted by department of Surgery in Department of General Surgery, Ananta Institute of Medical Sciences and Research Centre, Rajsamand

Study Duration:- The duration of the study over a period of one and half year.

Data Collection:- This study involved elective and emergency surgeries. Pregnant women and very elderly (>60 yr) were excluded. The group was split into group A and group B of 200 cases each. Group A comprised of patients who received a pre-operative single dose of Ceftriaxone. Group B received no such type of prophylactic antibiotic. The groups were split into two, taking consideration the type of surgeries, the age of the patient, the presence or absence of risk factors for development of SSI, and associated medical conditions, all of which were represented in both the groups almost equally and a comparative clinical study was made.

Data Analysis:-Data were analyzed by using Microsoft excel.

RESULTS

In our study, two groups were included, each group has 200 cases. In group A we had found 7% cases infected out of 200 cases, while in Group B had 34% infected cases out of total number of cases. In this study, we were included 10-50 age group of cases. Out of all cases we were found maximum infected cases from 41-50 ages in both groups. The incidence of risk factor also suggestive in this study in group A as well as in group B, which is showed in table no. 3.

Table 1: Distribution of groups according to infected cases

	Total no. of cases	infected cases	Percentage
Group A	200	14	7%
Group B	200	68	34%

Table 2: Distribution of groups according to age group

Age group	Group A	Number of infected cases	Group B	Number of infected cases
10-20	10	0	15	0
21-30	50	2	54	9
31-40	100	2	83	21
41-50	40	10	48	38

Table 3: Distribution of groups according to risk factor

Risk factor	Group A	Group B
Anemia	4	22
Prolonged duration of surgery	4	18
Diabetes mellitus	4	20
Obesity	2	8

DISCUSSION

For a prophylactic regimen to be effective, it should be directed against the most likely organisms. An Infection can be prevented only when the effective concentration of the drug is present in the blood and the tissues. Thus, antibiotic prophylaxis should begin just before the operation. Rao et al, observed in their study that SSI, incidence are doubled in the older age group 50- 70 yrs and severe complication following is increased in both extremes of ages i.e., < 10 yrs and > 60 yrs. Funary AP et al. found in their study that during the preoperative period blood glucose level were kept strictly below 200 mg/dl by continuous intravenous infusion of insulin reduced the incidence of SSI from 24% to 6.06% which was significant statistically. Some studies have revealed in their studies that diabetes mellitus is related with poor wound healing and high infection rates. Diabetes and the resultant hyperglycaemia lead to decreased function of leucocytes, especially phagocytosis. In the present study, 24 patients were diabetic.[9,10]

In the mid-1950s, the effectiveness of preoperative antibiotic prophylaxis is first shown in animals by Miles. If penicillin was given before guinea-pigs inoculation intradermal with Staphylococcus aureus, infection did not occur.[11]

Preoperative antibiotic prophylaxis was prescribed to prevent postoperative wound infection. On the other hand postoperative antibiotic for long duration has no effect in changing incidence of wound infection.[12]

CONCLUSION

To prevent surgical-site infections, it is essential for the surgeons to take appropriate steps to avoid local microbial factors. Simultaneously, it is also important to practice meticulous surgical techniques and unnecessary delay in the procedure. Prophylactic Antibiotics played a major role in reducing the post-operative wound infections.

ABSTRACT

Background: Every hour, 40 people under the age of 25 die in road accidents around the globe. According to the WHO, this is the second most important cause of death for 15 to 29 year olds. According to the latest report of National Crime Records Bureau or NCRB, Over 1, 37,000 people were killed in road accidents in 2013. Thoracic trauma forms one of the major parts of multiple traumas and is responsible for significant mortality and morbidity especially at younger ages.
Methods: We carried out a retrospective study to assess the prevalence of chest injury patients at Geetanjali medical college and hospital, Udaipur (Tertiary care rural centre) in last two years. Clinical details of the patients were recorded from their case sheets and were analyzed with reference to their age, sex, mode of injury, severity of injury, treatment employed, complication and final outcome etc.
Results: Males were predominantly involved (88.2%). Majority (61.9%) were in the age group of 21-30 years.
Conclusions: Chest injury occurs in a significant number of trauma patients and commonly affected victims are males of 20-40 years age. The majority of these patients were managed by simple intervention i.e., intercostals chest tube drainage and non –invasive ventilation, only less than 3% require thoracotomy.

Keywords: Blunt trauma, Flial chest, Haemothorax, Inter costal chest tube drainage

INTRODUCTION

Accidents which are unexpected and unplanned events are becoming the major epidemic of non-communicable disease in the present century. The number of accidental deaths in India is even higher than in the Western World[1]. Thoracic trauma contributes heavily to these figures which may present as isolated injury or as a part of polytrauma. Blunt thoracic injuries are thought to result from a combination of crushing, compression, stretching and shearing forces. The magnitude of these forces directly related to the rate of their acceleration and deceleration and also their relative direction of impact. Although most of the fractures of bony thorax are benign entities and can be followed up without hospitalization, trauma limited to the thoracic cage itself may cause profound pathophysiological alterations, which may be fatal if not promptly treated. On the other hand, the accurate identification of a patient at high risk for major chest trauma is essential for regulation of over and under triage within a trauma system. The present study focuses on blunt chest injuries, especially rib fractures and associated injuries. In spite of the high mortality rates, about 90% of the patients with life-threatening thoracic injuries can be managed by a simple intervention like intercostals tube drainage and non invasive ventilation.[12]

Table 5: Indication for thoracotomy.

Indication	No of patients
Massive bleeding	4
Oesophageal rupture	1
Chylothorax	1
Multiple displaced fracture	3
Diaphragmatic rupture	3

Thoracotomy was needed for twelve patients. Removal of intrathoracic hematoma and control of massive bleeding in four patients, for esophageal repair in one patient, for chylothorax in one patient, and thoracic wall stabilization and control of bleeding in three patients. Three patients underwent thoracotomy or laparatomy due to diaphragmatic rupture.

If we analyse the final outcome of all the chest injury patients (730), 615 patients were discharged in satisfactory condition within 7-9 days, while hospital stay was prolonged in 98 patients because of multiple rib fracture associated with other extra thoracic injury and various complication. Various complication were noted in 43 patients mainly residual hemothorax, recurrent pneumothorax, deep vein thrombosis, broncho pleural fistula, ARDS, aspiration pneumonitis ,pressure sore etc..17 patients could not be saved despite adequate and aggressive treatment. Out of 17 patients who expired, 10 were having multiple fractured ribs with associated abdominal injury and pelvic fracture. 7 patients were having flail chest with massive bilateral pulmonary contusion.

Table 6: Final outcome.

Final result	No. of patients
Discharge	615
Complication	43
Death	17

DISCUSSION

Trauma is the leading cause of mortality and morbidity during the first four decades of life, and one of the commonest causes of death all over world, more in India. The major reasons for blunt chest injuries are traffic accidents with an incidence of 70–80%.[2] Increased automobile traffic and ever increasing population together with intentional or unintentional ignorance of traffic rules account for the predominance of road-side accidents producing chest trauma. In 79.7% of our patients, traffic accidents were the cause of injuries which is consistent with the literature.[1] These findings were in accordance with the studies of Helling and Mattox, in which road accidents constituted the maximum number of cases.[3,4] The right side of the chest was involved commonly. The higher percentage of younger age group patients in the present study is comparable to studies of Muckart and Locurto et al Males outnumbered females by a huge margin because of their greater exposure to outdoor activities like drivers, industrial workers and labourers etc. These findings were comparable to findings of other studies.[5]

Subcutaneous emphysema is a clear indication of injury to the respiratory tract. All of the patients with subcutaneous emphysema had fractured ribs, which also led to lung injury. Kalyanaraman et al reported that lung injury seems to be associated with rib fractures in 74% of cases with subcutaneous emphysema.[9]

The presence of more than two rib fractures is a marker of severe injury. 59.86% of our patients had hemothorax and/or pneumothorax and most of them presented with associated extrathoracic injuries. Mortality rate was nil in patients with less than two rib fractures versus 4.14% in patients with more than two rib fractures. Lee reported that mortality doubles (1.8 versus 3.9%) for patients with three or more rib fractures and those with no rib fractures.[7] The presence of fractures of the first or second ribs has also been reported to be indicative of severe trauma. Poole reviewed all series of fractures of first and second ribs and found a 3% risk for aortic injury and a 4.5% risk for injury to a brachiocephalic vessel [8] However, no association between victims of trauma with or without rib fractures and aortic injury was reported.[7,8] In our series, we did not observe any major vascular injury.

In our study, the majority of patients (410) had fractures of more than two ribs and additionally 46 patients had flail chest; 242 patients had fracture of either one or two ribs and most of them could be managed by just observation with check x-ray of the chest after 24 hours of injury. With single or two rib fractures the incidence of pneumothorax/haemothorax is not as high but there is increasing likelihood of this complication as the number of fractured ribs increases.11 Flail chest was present in 46 patients in our series which was consistent with Pate who described flail chest occurring in about 8-10% percent of chest trauma patients.[9]

Regarding treatment profile, intercostal drainage was required in 331 patients and thoracotomy was needed in 12 patients only. Various indications of thoracotomy were as per Table 5. The commonest indication was massive bleeding, following ICD. Out of 730 patients, 331 patients were treated by simple Inter Costal tube drainage. Time taken for full expansion of the lung and removal of the chest tube was 2-8 days. In a study by Locurto, the chest tube was kept for an average 4.5 days with simple underwater seal drainage.[3]

Residual haemothorax was the commonest complication in our series, 24 of which were treated by simple aspiration while the remaining 2 required repeat ICD. Drummond observed residual haemothorax in about 15% of patients with haemopneumothorax where simple ICD was done. 6 there was no evidence of empyema in any

patient. The incidence of empyema has been reported about 2 to 3 percent in patients with chest injury requiring tube thoracostomy in various studies.[6,12]

Overall, there were 17 deaths in this series, with most of patients having multiple fractures with flail chest and massive pulmonary contusions associated abdominal injuries and pelvic fracture. The mortality rate after severe chest injury was comparable with other studies reported in the literature.[12] The clinical state of the patient, severity of the trauma, age, presence of more than two rib fractures, presence of flail chest, and possible intrathoracic injury help in making the decision for proper treatment plan.

CONCLUSION

After comprehensive review of the present study, it is concluded that:

- Blunt trauma, mainly road-side accidents formed the most common cause of chest injury, followed by assault and falls from height etc. and commonly affected victims are males of productive age.
- The majority of these patients can be managed by simple intervention i.e., intercostal drainage. Patient with multiple rib fracture can be managed by non invasive ventilation and only few require thoracotomy.
- The risk of mortality in chest trauma has been associated with the presence of more than two rib fractures, age older than 60 years and with associated head and abdominal injury.
- The ability to identify those patients having significantly higher risk for morbidity and mortality ensures the establishment of treatment priorities and efficient management of existing injuries.

ABSTRACT

Background: Necrotizing soft-tissue infections are infection of any of the layers within the soft tissue compartment that are associated with necrotizing changes. These infections are highly lethal if not diagnosed. The purpose of this article is to assess the different diagnostic tools.
Methods: We carried out a retrospective study to assess the prevalence of soft tissue infections at Geetanjali medical college and hospital, Udaipur (Tertiary care rural centre) in last four years. Clinical details of the 216 patients with soft tissue infection were recorded from their case sheets and were analyzed with reference to their age, sex, risk factor, symptoms, etiology, microbiology, treatment employed, complication and final outcome etc.
Results: Pain and swelling were commonest presenting symptoms found in every case. Diabetes and Trauma were major predisposing factor in our series. NSTI differ from NNSTI with respect to presence of blister (50% versus 5.8%), Dusky discoloration (58.3% versus 0%), Necrotic skin (51.04% versus 0%) and Crepitance (6.2% versus 0%). In present series' most common organism causing NSTI in our institute is gram negative bacilli .Prompt resuscitation followed by early and adequate debridement remains the cornerstone of management of NSTI.
Conclusions: Diagnosis of necrotizing infection is challenging but there are enough tools including clinical findings, biochemical parameters, imaging aids and invasive procedures that can help make the diagnosis. When in doubt, exploration of the compromised tissue should be performed. The mainstay of treatment is early and adequate surgical debridement.

Keywords: NSTI- Necrotizing soft-tissue infections, NNSTI - Non- Necrotizing soft-tissue infections, Debridement

INTRODUCTION

Necrotizing soft-tissue infections (NSTIs) are highly lethal infections. These infections were first described by Jones in 1871 and termed as "hospital gangrene".[1] Since then, multiple descriptions of NSTI have been published, and a wide number of terms, definitions, and classifications have been used.[2-5]

In 1951, Wilson coined the term "necrotizing fasciitis" to encompass some of these infections that is rapidly spreading and potentially devastating infection of the superficial and deep fascia with secondary necrosis of the overlying skin.[6]

The early diagnosis is main challenge in treating patients with NSTI, and knowledge of various clinical sign and laboratory markers can be helpful for distinguishing between cases of cellulitis, which should respond to

In present series' most common organism causing NSTI in our institute is gram negative bacilli followed by haemolytic streptococci. Most of the infection was polymicrobial in nature.

Table 5: Distribution of mode of treatment.

Management	No. of Pt.	% of Pt.
Multiple release incision and fasciotomy.	26	27.08
Debridement	68	70.83
Amputation	2	2.08

In our series debridement was done in 70.8% of cases with in 8 hours of admission after initial resuscitation. Multiple release incision and fasciotomy was done in 22.9% of cases while amputation at mid-thigh level was done in 2 cases to save life of patient.

infected tissue that controls the source of infection and allows for future recovery. Broad-spectrum antimicrobial therapy should be started early to include coverage for gram-positive, gram-negative, and anaerobic organisms. Special consideration for group A *Streptococcus* and *Clostridium* species should be taken. Acceptable regimens include monotherapy agents, such as imipenem, meropenem, ertapenem, piperacillin/tazobactam, and tigecycline. Multidrug regimens have also been described, including triple-drug therapy regimens, such as high-dose penicillin, high-dose clindamycin, and a fluoroquinolone or an aminoglycoside for coverage of gram-negative organisms. Vancomycin, daptomycin, or linezolid should be included in the regimen until methicillin-resistant staphylococcal infection has been excluded. Antimicrobial administration should be continued until no further debridements are needed and the patient's physiology has improved.

Debridement of the necrotic tissue should be undertaken as soon as possible as it is probably the most important determinant of outcome in necrotizing soft tissue infections. This was well described in a study by Bilton, et al in which patients with necrotizing soft tissue infections who had adequate surgical debridement (early and complete) were compared to those with either delayed or incomplete debridements. The mortality in the latter group was 38% compared to 4.2% in the group receiving adequate surgical treatment.[14] During the operation, a generous incision is performed and if needed, the incision is extended to allow for complete debridement of the infected or necrotic tissue. Occasionally, amputation of a limb is necessary to achieve this goal to save life of patient. Healthy, viable, bleeding tissue should be present at the edges of the excision site, and aggressive resuscitation should accompany the perioperative period. Once the initial debridement has been done, management in an intensive care unit is recommended, and scheduled debridements at intervals of 6-48 h should be performed until no further necrosis or infected tissue is seen. Finally, physiologic support, combined with close monitoring in an intensive care unit is encouraged. It is not uncommon to see patients with NSTI develop organ failure, such as acute renal failure and acute respiratory distress syndrome, which require replacement therapies.

The most important discriminative information to be established in patients with soft-tissue infection is the presence of a necrotizing component. This will confirm NSTI, and by definition, will identify patients that require surgical debridement. The first and most important tool for early diagnosis of NSTI is to have a high index of suspicion. When in doubt, exploration of the compromised tissue should be performed. Intravenous drug user are found to be high-risk group for developing necrotizing soft tissue infections, and when evaluated for soft tissue infections they should undergo a thorough assessment that can confidently rule out a necrotizing infection. The mainstay of treatment is early and adequate surgical debridement with scheduled returns to the operating room. We have also observed that cases of NSTI without a recognized precipitating factor are more likely to be caused by group a streptococcal infection. More recently, NSTI without a recognized precipitating factor has also been identified with community-acquired methicillin-resistant staphylococcal infection.[14]

Since the first description by Jones, mortality in patients with NSTI remains high. He reported a mortality rate of 46%, and a recent pooled analysis determined it to be ~34%.[1,15] More recent series have reported mortality rates with a range of 16%, 24%, a rate that, although lower than the rate 100 years ago, still accounts for high mortality associated with NSTI. In our series mortality rate was 16.66 % .This low rate is related with early and adequate debridement within 8 hours of admission and aggressive critical care of these pt.

Bosshardt, et al published a series of patients with predominantly intravenous drug use-related necrotizing soft tissue infections over a 5-year period and showed that the incidence more than doubled when compared to the first years of the study.[20]

CONCLUSION

We also draw following conclusion. Pain and swelling were commonest presenting symptoms found in every case. Diabetes and Trauma were major predisposing factor in our series. NSTI differ from NNSTI with respect to presence of blister (50% versus 5.8%), Dusky discoloration (58.3 % versus 0%), Necrotic skin (51.04% versus 0%) and Crepitance (6.2% versus 0%). So Bullae, necrotic skin, dusky discoloration and crepitance are strongly predictive of NSTI. Four laboratory criteria that are strongly suggestive of NSTI ($P< 0.001$) i.e. statistically significant. Total Leucocytes Count more than 15 X 10 9/L. S. Creatinine more than 1.5 mg/dl.Serum Na+level less than 130 mmol/L. Presence of gas in x-ray of affected part. In present series' most common organism causing NSTI in our institute is gram negative bacilli followed by haemolytic streptococci. Most of the infection was polymicrobial in nature. Prompt resuscitation followed by early and adequate debridement remains the cornerstone of management of NSTI. Wound inspection after 24 hours to confirm the adequacy or to complete debridement. In conclusion of our study we would like to say that lack of awareness among clinician may play a major role in delay of diagnosis and institution of therapy that leads to subsequent high mortality and morbidity. The most important factor in survival in present series was related to rapidity of debridement within 8 hrs of admission after initial resuscitation. Utilizing these principal the morbidity and mortality of patients with NSTI should be substantially reduced.

ABSTRACT

Background: Peptic perforation is a life threatening complication of peptic ulcer disease requiring prompt surgical management. Omental patch repair with peritoneal lavage is the mainstay of treatment for perforated peptic ulcer at most of the centres. Laparoscopic repair has been described by various authors since 1990 in different part of world. In current study we have assessed the feasibility and safety of use of laparoscopy for this life threatening surgical emergency. The outcome were analyzed in terms of operating time, post-operative complications, medication, hospital stay, morbidity and mortality.
Methods: This study was carried out in period of two years from January 2012 to December 2013. Patients were initially assessed in emergency department and then after resuscitation taken up for surgery. Patients with provisional diagnosis of perforated peptic ulcer were included in the study, meeting inclusion criteria.
Results: Total 30 patients were studied out of total 38, who were operated in the study period. 26 males and 4 females, age ranged from 18-60 years, operative time was 55 to 110 minutes. In post-operative period the need for intravenous medication (analgesics and antibiotics) was less, early assumption of routine activity and early discharge. A very important factor noted that patient were psychologically so happy and convinced that they did not have big wound over abdomen and they can resume their routine activity as before.
Conclusions: Laparoscopic repair of perforated peptic ulcer is safe and effective in experienced hands in most of the patients. It offers all advantages of laparotomy without compromising the safety and outcome.

Keywords: Perforated peptic ulcer, Laparoscopy

INTRODUCTION

Peptic ulcer is a well-known disease widely prevalent in all socio economic strata all over world. The management of this common disease has evolved over a period of time. Current medical management with proton pump inhibitors and H.pylori eradications has drastically reduced the various complications and need of surgical interference. Still, peptic perforation is quite prevalent life threatening surgical emergency encountered in general surgical practice. Omental patch repair (modified Graham repair) with thorough peritoneal lavage is the mainstay of treatment at most of the centers.[1]

Laparoscopy has emerged as gold standard for surgical treatment of various diseases in last 2-3 decades due to it's certain advantages like less post-operative pain, less hospital stay, less wound complications, early return to normal activity etc.[2]

This study is aimed to assess the feasibility, safety and advantages of use of laparoscopy in the treatment of this

unchanged. Minimal access surgery has gained wide acceptance amongst surgeons and general public all over world due to its definitive advantages. Although there are still some constrains amongst conventional surgeons for the use of this technique in certain surgical emergencies.

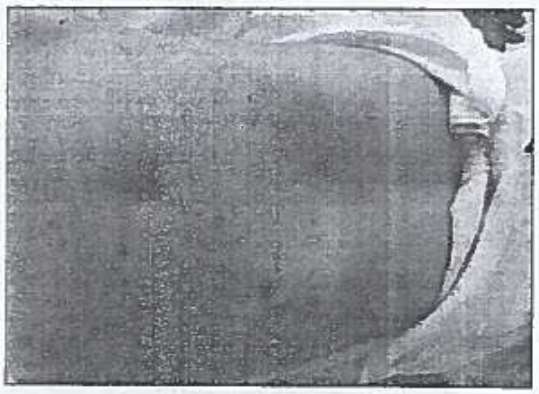

Figure 1: Post-operative photograph showing port position for laparoscopic peptic perforation repair.

In 1990 Mouret et al. reported the first laparoscopic sutureless fibrin glue omental patch for perforated duodenal ulcer repair.[1] The first successful laparoscopic suture repair for perforated peptic ulcer was described by Nathanson et al. in 1990.[5] Since then, many studies has been conducted by various authors in different part of world to define the use of laparoscopy in surgical management of perforated peptic ulcer. Costalat et al reported combined endoscopic and laparoscopic approach using ligamentum teres hepatis.[7] In 1993 Darzi et al, and Nassar et al in 1994 reported laparoscopic omental patch repair with use of automated stapler.[12,13] Siu WT et al described single stitch laparoscopic omental patch repair of perforated peptic ulcer in 1997.[3] Masao Matsuda et al from Japan also published an article suggesting that laparoscopic omental patch repair offers advantages of laparoscopic surgery and an attractive alternate to open surgery.[17]

After Mouret and Nathanson many authors worked in this field and described various techniques of perforated peptic ulcer closure i.e. simple suturing, by gelatin sponge and fibrin glue, stapled omental patch repair, gastroscopy assisted insertion of ligamentum teres hepatis to close the perforation, gastroscopic guided omental plugging to close the perforation.[22] single suture with omental patch repair.[3]

Studies were done to compare open versus laparoscopic repair.[16,19,20,23] Siu et al and found that laparoscopic repair was superior then open in terms of size of incision, requirement of post op analgesia, less hospital stay, early return of normal activity, less immediate and long term complications etc. although the operating time was more in laparoscopic group in some studies but can be reduced by adopting certain techniques and with more and more experience. Almost all study groups recommended proper selection of patients and demands surgeons having good laparoscopic suturing skills and experience.

In our study, after analyzing the results it was found that duration of surgery was between 55-110 minutes. Time taken was more in initial cases and in few more contaminated cases, after that the operating time was nearly same as we take in open surgery and even less in few cases. Post operatively patients needed round the clock Intravenous analgesics for 2-3 days, Ryles tube could be removed in 2-3 days except in two cases in which we had to keep ryles tube for 4 days which was badly contaminated large perforation of about 1cm, we have started oral feeding in 3-4 days in most of the cases except in 5 cases which were having large perforation with more peritoneal contamination. Hospital stay was 4-5 days in most of the cases; only 3 patients had 6 days stay. 2 patients had chest complications in immediate post op period which were managed comfortably in ICU and recovered in 2-3 days. There was no wound gap, no burst abdomen, no residual collection or pelvic abscess noted in any case. No incidence of any incisional hernia was noted in any case. Patients were allowed and encouraged to return to the normal activity after 7-10 days. No mortality was noted in our series.

CONCLUSION

The management of this common disease is evolved over a period of time. Current medical management has drastically reduced the various complications and need of surgical interference. Still peptic perforation is quite prevalent. Gold standard treatment is conventional laparotomy and omental patch repair (modified Graham repair). Laparoscopy has emerged as gold standard for surgical treatment of various diseases in last few decades. We conclude with the present study that laparoscopy is an effective tool in the surgical management of perforated peptic ulcer.

It requires experience and technical expertise in laparoscopic surgery. If proper selection of patients is done laparoscopic repair is safe and feasible. It does not increase the cost of treatment infact it helps in reducing the cost by less hospital stay, less medication required, less morbity, early return to normal activity and to workplace. We hereby recommend laparoscopic repair in selected patients as treatment of choice as it offers all the advantages of laparoscopy without increasing the risk. It is a safe, effective and cost effective method for the treatment of perforated peptic ulcer.

ABSTRACT:

OBJECTIVES: Present study was planned to compare the postoperative outcome of surgical evacuation of chronic subdural haematoma (SDH) through two burr hole technique versus single burr hole with partial excision of membrane technique. **METHODS:** All patients admitted in neurosurgery ward of Geetanjali Medical College and Hospital, Udaipur were evaluated by taking detailed history, clinical examination and investigations. After confirmation of chronic SDH by CT/MRI scan patients were operated. Initial 50 patient were operated by two burr hole technique and last 50 patient were operated by using single burr hole with parted excision of membrane technique. **RESULTS:** 50 patients were operated by Two Burr Hole technique and the duration of operation ranged from 15 to 40 min. Most of the symptoms relieved postoperatively within 6 hours to 6 days. Hospital stay found with average of 6.5 days. During follow-up 3 patients showed recurrence. The results after 3 months follow up were excellent in 86 %. 50 patients were treated with Single burr hole with partial excision of membrane technique techniques. The duration of operation ranged from 10-30 minutes. Most of the symptoms relieved within 6 hours to 6 days. Hospital stay of patients was with average of 5 days. Two patients, showed re-accumulation of chronic SDH during follow up. The results after 3 months follow up were excellent in 90 %. **CONCLUSIONS:** With this study, we have reached to the conclusion that single burr hole evacuation of chronic SDH with partial excision of membrane technique is simple, safe, less time consuming and effective treatment of chronic SDH.

Keywords: Chronic subdural haematoma, two burr hole technique , single burr hole technique.

INTRODUCTION

Chronic subdural haematoma (Ch. SDH) is a well-known entity and common surgical disorder managed by neurosurgeon and if not recognized and treated timely, may prove fatal. It can be non traumatic or post traumatic and all of them need urgent attention irrespective of etiology. (1) It manifest with progressive neurologic deficit that occur later than 2 weeks following head

Postoperative Management:-

Careful record of postoperative progress was kept in both of the groups as per standard format along with any postoperative complication. Early mobilization of patient was encouraged postoperatively. Patients were discharged at appropriate time and advised for regular follow up. Total duration of hospital stay and the mortality was noted. Follow up of the patients done for three months.

RESULTS:

The study was done on 100 patients of Ch. SDH admitted in neurosurgery ward during year 2000-2003. Out of these 100 patients most of the patients belonged to 6^{th} and 7^{th} decade of life. 17 % of Patients were in 8^{th} decade of life and ranged from 8 to 92 years,

20 % of the patients were female as compared to 80 % males. 60 % of patients were from urban population while 40 % patients were rural. The cause of urban preponderance is probably easy availability of CT scan and early approach to doctor in urban areas. Most of the patients presented with headache followed by weakness and paralysis, irrelevant talk, mental slowing fluctuating drowsiness etc. Eight of our patients presented with COMA. Previous head injury was found to be most common etiology in 68 patients.

Two Burr Hole technique :

50 patients were operated by this technique the duration of operation ranged from 15 to 40 min average of 30 min. 43 patients showed dramatic relief in symptoms postoperatively and most of the symptoms relieved within 6 hours to 6 days. Early mobilization of patients was encouraged in 3 patients showed partial improvement and 4 did not show any improvement. Hospital stay ranged from 2 to 24 days with average of 6.5 days. Four patients died postoperatively who presented with coma and did not show any improvement postoperatively.

During follow-up 3 patients showed recurrence. Needle aspiration was done but patients repeatedly returned back even after several re-aspiration of haematoma fluid. Finally, decision of membranectomy was taken and following membranectomy no any patient showed recurrence.

The results after 3 months follow up was excellent in 86 % in which, most of the symptoms relieved and patient showed no reccurence ,fair 6% in which patients showed recurrence and 8 % poor in which patients did not improved and died.

Single burr hole with partial excision of membrane technique

50 patients were treated with these techniques. The duration of operation ranged from 10-30 minutes, with average of 20 minutes. 45 patients showed dramatic improvement and most of the symptoms relieved within 6 hours to 6 days. Early mobilization was encouraged. 2 patients showed partial improvement and 3 patients did not show any improvement in symptoms.

Hospital stay of patients was ranged from 1 to 23 days with average of 5 days. Three patients died postoperatively; 2 of them were those who presented in deep coma with a prolonged history and found to have re-bleed following membranectomy. During follow up two patients

our study, mortality rate was 6% in single burr hole partial excision of membrane technique and 8% in two-burr hole technique. Mortality was because of haematoma.

A retrospective study mode by Benzel et at on 111 patient using single burr hole irrigation technique and postoperative outcome at 6 weeks was excellent in 90%. Fair 5.5 % and poor 4.5 %.(19) In our study, the post of outcome after 3 months was excellent 90%o fair 4 % and poor 6 % in single burr hole and partial excision of membrane technique and excellent 86%, fair 6%, and poor 8% in two burr hole technique.

CONCLUSION:

With this study, we have reached to the conclusion that single burr hole evacuation of Ch. SDH with partial excision of membrane technique is simple, safe, less time consuming and effective treatment of Ch SDH. Only one burr hole is required in this technique postoperative hospital stay is less and less re-accumulation of blood as well as number of aspiration with this technique, of course partial excision of membrane helps in it.

Other significant factors in the study were early mobilization of patient and no drain was used which most of authors recommend. Because of this reasons we have shifted from two-burr hole technique to single burr hole with partial excision of membrane technique.

Abstract
Abdominal tuberculosis is an increasingly common disease that poses diagnostic challenge, as the nonspecific features of the disease which may lead to diagnostic delays and development of complications. This condition is regarded as a great mimicker of other abdominal pathology. A high index of suspicion is an important factor in early diagnosis. Abdominal involvement may occur in the gastrointestinal tract, peritoneum, lymphnodes or solid viscera. Various investigative methods have been used to aid in the diagnosis of abdominal tuberculosis. Early diagnosis and initiation of antituberculous therapy and surgical treatment are essential to prevent morbidity and mortality. Most of the patients respond very well to standard antitubercular therapy and surgery is required in some cases. Imaging plays an important role in diagnosis of abdominal tuberculosis because early recognition of this condition is important.
Abdominal tuberculosis constitutes a chief public health setback, presents a diagnostic challenge requiring a high index of clinical suspicion. Young age at presentation, delayed presentation, poverty & high morbidity & mortality are among the hallmarks of the disease in this region. These challenges need to be addressed in order to deliver optimal care for these patients. Early diagnosis, early antituberculous therapy & surgical treatment of the related complications are important for survival.

Keywords: Surgical, Abdominal & Tuberculosis.

Introduction
Tuberculosis (TB) is a life threatening disease which can virtually affect any organ system [1]. Abdominal TB comprises around 5 percent of all cases of TB [2]. The prevalence of TB has increased in both immunocompetent and immunocompromised and it can affect virtually any organ. The primary site of TB is usually lung, from which it can get disseminated into other parts of the body. The other routes of spread can be contiguous involvement from adjacent tuberculous lymphadenopathy or primary involvement of extrapulmonary organ. The diagnosis of extrapulmonary TB can be difficult as it presents with nonspecific clinical and radiological features and requires high degree of suspicion for diagnosis. The abdominal TB, which is not so commonly seen as pulmonary TB, can be a source of significant morbidity and mortality and is usually diagnosed late due to its nonspecific clinical presentation [3]. Approximately 15%-25% of cases with abdominal TB have concomitant pulmonary TB [4, 5]. Hence, it is quite important in identifying these lesions with high index of suspicion especially in endemic areas. ABDOMINAL TB is a type of TB that affects the Gut, Peritoneum, Abdominal lymph nodes and more rarely the solid organs in the abdomen (liver, pancreas, spleen). Abdominal TB leads to severe illness in adults and children and can cause complications such as bowel perforation can lead to death. Risk factors for development of abdominal TB include cirrhosis, HIV infection, diabetes mellitus, underlying malignancy, treatment with anti-tumor necrosis factor (TNF) agents, and use of peritoneal dialysis [6-10]

Material & Method
It is a prospective observational study including 100 patients were part of this study conducted from Dec 2019 to June 2020 with a diagnosis of abdominal tuberculosis confirmed histopathologically carried out in Bundelkhand Medical College, Sagar, Madhya Pradesh, India Detailed clinical examination of patients were evaluated. Investigations viz. blood CBC, RBS, serum urea, creatinine, BT, CT, Electrolytes, HbsAg, HIV, urinalysis, ECG, X-ray chest P.A.

In our study group four patients were treated conservatively and had recovered without any surgical intervention. There was mortality of two patients due poor general condition, fecal peritonitis and ongoing septicemia at the time of admission. Similar findings have been reported by Sadia J [13]

Conclusion

Abdominal tuberculosis constitutes a chief public health setback, presents a diagnostic challenge requiring a high index of clinical suspicion. Young age at presentation, delayed presentation, poverty & high morbidity & mortality are among the hallmarks of the disease in this region. These challenges need to be addressed in order to deliver optimal care for these patients. Early diagnosis, early antituberculous therapy & surgical treatment of the related complications are important for survival.

ABSTRACT

Background: The objective of present study was to compare the advantage of vaginal hysterectomy over abdominal hysterectomy in non-descent uterus.

Methods: A non-randomized controlled trial was carried out in the Bundelkhand Medical College, Sagar and associated hospital from October 2015 to September 2017. A total of 150 cases were included in the study. Out on 150, 75 underwent vaginal hysterectomy for non-descent uterus and other 75 underwent abdominal hysterectomy for similar indications.

Results: Among total 150 cases, 75 were underwent non-descent vaginal hysterectomy and similar number of cases underwent abdominal hysterectomy. Common age group was 35-54 years. Commonest indication was DUB (48.7%). Postoperatively, complications were more common in those who underwent abdominal hysterectomy such as ambulation (18 hours), incidence of nausea, vomiting, abdominal discomfort, bladder injury and wound infection were less in vaginal hysterectomy compared to abdominal hysterectomy. It was also observed that blood transfusion requirement, operative timing and hospital stay (3 days) were less in vaginal hysterectomy group.

Conclusions: Vaginal hysterectomy for benign gynecological disorders is a safe, effective, least invasive and is associated with lesser complications as compare to abdominal hysterectomy. Today in the era where patient is more cosmetically concern, vaginal hysterectomy for non-descent uterine disorder needs to be considered as good and safe option.

Keywords: Nausea, Non-descent uterus and abdominal hysterectomy, Vaginal hysterectomy, Vomiting

INTRODUCTION

Hysterectomy is one of the most frequently performed elective major surgery in day to day Gynaecological practice. It can be done by open i.e. abdominal or vaginal route and laparoscopic route. Laparoscopy assisted vaginal hysterectomy (LAVH) and total laparoscopic hysterectomy (TLH) although gaining more popularity, is associated with higher cost, longer duration of surgery, and specially trained personnel.[1] Most of the literature supports the view that vaginal hysterectomy, when feasible, is the safest and most cost-effective procedure for removal of the uterus.[2] Nevertheless, the abdominal route is the most commonly chosen, 66% of hysterectomies are performed abdominally, 22% are performed vaginally, and 12% are performed laparoscopically.[3]

In today's world, vigorous attempts are being made to reduce the number of abdominal hysterectomy and replace them with vaginal hysterectomy or laparoscopic assisted vaginal hysterectomy as the next choice. It is

Table 2: Parity distribution.

Parity	VH n (%)	AH n (%)
0	4 (5.3)	7 (9.3)
1	6 (8)	5 (6.66)
2	30 (40)	35 (46.66)
3	21 (28)	26 (34.66)
4	12 (16)	10 (13.33)
5	2 (2.66)	2 (2.66)
Total	75	75

Chi= 1.38, p= 0.925

As shown in Table 2, hysterectomy (Vaginal or abdominal) is common in parity 02, and there was no significant difference.

Table 3: Diagnosis.

Diagnosis	VH n (%)	AH n (%)
DUB	35 (46.66)	39 (52)
Fibroid	28 (37.33)	27 (36)
Adenomyosis	8 (10.66)	6 (8)
PID	4 (5.33)	3 (4)
total	75	75

Chi= 0.66, p= 0.88. Not significant

Table 3 shows, commonest indication for both vaginal and abdominal hysterectomy is DUB followed by Uterine fibroid.

Table 4: Complications in VH and AH group in NDVH.

Complication	VH n (%)	AH n (%)	Chi square/ Fisher exact test, p value	Significance
Haemorrhage requiring blood transfusion	6 (8)	12 (16)	0.2082	Not significant
Bladder injury	2 (2.66)	5 (6.66)	0.4419	Not significant
UTI	1 (1.33)	6 (8)	0.1162	Not significant
Nausea / vomiting	4 (5.33)	16 (20.8)	0.0070	Significant
Abdominal distention	4 (5.33)	10 (13.33)	0.1587	Not significant
Wound infection	2 (2.66)	8 (10.66)	0.0976	Not significant

In the Table 4, there were 6 cases of haemorrhage requiring blood transfusion in vaginal group and 12 cases of haemorrhage requiring blood transfusion in abdominal. There were 2 case of bladder injury in vaginal group and 5 in abdominal. In the present study, post-operative complications like, UTI, abdominal discomfort and wound infection were more common in abdominal cases, but the difference was found to be statistically non-significant. Nausea, vomiting was significantly higher in abdominal hysterectomy (p=0.0070).

Table 5: Ambulation.

Duration of ambulation	VH n (%)	AH n (%)
Less than 12 hours after surgery	25 (33.33)	2 (2.66)
12 to 24 hours	40 (53.33)	15 (20)
More than 24 hours after surgery	10 (13.33)	58 (77.33)
Total	75	75

Chi= 64.83, p<0.0001, Highly significant

As shown in Table 5, majority of the patients in the vaginal group ambulated within 24 hours, while abdominal group ambulated after 24 hours. Mean time taken for ambulation in vaginal group is 18±4.81 and abdominal group is 32.06±5.37 which was statistically significant.

Table 6: Surgical results.

Parameter	VH	AH
Average operating time	50.43±7.256 min	86.6±8.363 min
Patient required blood transfusion due to hemorrhage	6	12
Average hospital stays in days	3	5

Table 6 shows, vaginal group was associated with less operative time, less intra-operative bleeding and early hospital discharge of patients.

DISCUSSION

As compare to abdominal approach, vaginal approach to hysterectomy has been gaining popularity among surgeons, now a day's patients are desperate to avoid an abdominal incision and demand scarless surgery. Vaginal route allows the surgeon to operate by the least invasive route of all, utilizing an anatomical orifice. Unfortunately, 70% to 80% of hysterectomies are performed by abdominal route and vaginal approach is usually reserved for uterovaginal prolapse.[7] With adequate vaginal access and good uterine mobility, vaginal hysterectomy can be easily performed.

HOW TO CITE THIS ARTICLE:
Vishal Gajbhiye, Nagendra Singh, Sona Singh, Dushyant Rohit, Omkar Thakur, R. S. Verma. "Orchidopexy without Ligation of Hernia SAC: Our Experience". Journal of Evolution of Medical and Dental Sciences 2015; Vol. 4, Issue 30, April 13; Page: 5150-5153, DOI: 10.14260/jemds/2015/752

ABSTRACT: AIMS: To confirm that, the ligation of hernial sac during orchiopexy is not mandatory to prevent postoperative development of hernia. **METHODS:** This prospective study was conducted in 40 children with an age range of six months to 12 years with a diagnosis of undescended testis. Of the 40 cases, 30 were unilateral and 10 bilateral cases. Of the 30 unilateral undescended testis, 18 were right-sided and 12 left-sided. All children underwent standard orchiopexy without the ligation of the hernia sac. **RESULTS:** All the patients were followed up regularly up to a period ranging from 18 months to 24 months. No inguinal hernia was detected during the regular follow-up in any child. **CONCLUSION:** Ligation of herinal sac is not mandatory during orchipexy.
KEYWORDS: Undesended testes, inguinal hernia, orchidopexy.

INTRODUCTION: Herniotomy is performed along with orchidopexy for the closure of associated patent processus vaginalis. The conventional technique for undesended testis repair is high ligation of the hernial sac after proper dissection upto the deep ring, Mohta et al.[1] Observed that there is no untoward effect on the early complications and recurrence rate, if hernia sac is not ligated during herniotomy. During laparoscopic orchidopexy performed for contralateral testicle it was found that despite nonligation, the previous de peritonalized site got reperitonalized by itself and the sac which is dissected and left open deep to deep ring is not having hernia later in life. This is probably due to the closer of peritoneal defect within 24 hours by metamorphosis of the in situ mesodermal cells.[2]

We done a study on non-ligation of hernia sac during conventional orchiopexy in our institute to see the results and it's long term untowards effects and advantages over standard orchiopexy.

MATERIALS AND METHODS: This prospective study was conducted between May 2011 and Dec. 2014. Fourty children with an age range of six months to 12 years with a diagnosis of undescended testis were included. Of the 40 cases, 30 were unilateral and 10 bilateral cases. Of the 30 unilateral undescended testis, 18 were right-sided and 12 left-sided. In all the cases, testis was palpable. Only those cases were taken which were not associated with clinical hernia. Baseline investigations were done, informed consent of the parents was taken and the procedure explained to the parents. All children underwent standard orchiopexy without the ligation of the hernia sac.

The hernia sac was dealt with after complete mobilization of the testis through an inguinal incision. The sac was first opened up, divided and the proximal end of the divided sac was very gently peeled off with dissecting forceps as high as possible without damaging the cord structures. This was done to bring down the testis to its normal position as it results in achievement of adequate length of the cord as describe in standard orchidopexy technique. The dissected hernia sac was not ligated and left as such. Standard orchiopexy was then performed by making subdartos pouch. All the patients were followed up regularly up to a period ranging from 18 months to 24 months.

DOI: 10.14260/jemds/2015/752

processus vaginalis; myofibroblasts are found in association with smooth muscle. Smooth muscles dedifferentiation into myofibroblasts. This dedifferentiated state may represent attempted apoptosis, which results in disappearance of the smooth muscle and obliteration of the processus vaginalis after the descent of the testis into the scrotum.

Undescended testis may not share the same etiologic basis as hernia, because the sacs associated with undescended testis are without smooth muscles.

Handa et al.[6] Intentionally did not close the internal ring around the pulled-through spermatic cord. This approach was based on the observation that the majority of the testes lie near the internal ring. The mobilization of these testes by division of the gubernaculum and the dissection required to free a long loop vas deferens results in a large raw area at the internal ring. When the testis is pulled down into the scrotum, the mobilized surface of the spermatic cord is in apposition with the raw area at the internal ring.

As per many resent studies surgeons concluded that herniotomy in cases of hernia alone and hernia associated with UDT, hernial sac ligation is not required.[1],[2],[9],[10]

In our study, during inguinal orchiopexy, we did not ligate the hernia sac. After freeing the hernia sac from the cord, we simply dissected the hernia sac as high as possible and cut the proximal end near deep inguinal ring. We have performed 40 cases of inguinal orchiopexy with this procedure and followed up for 18 months to two years. We did not find any complication or untoward effect in any of our study cases.

Advantages asscociated with this advancement in standard procedure are:

1. Time saving: Several minutes of operating time are saved as we can avoid the holding of the proximal cut end of the hernial sac with multiple small haemostatic forceps and suture ligating it, especially when the sac is very thin and tends to tear very easily.
2. Length of testicular vessel: It is found that the most important criteria for bringing down the testes in the scrotum is the length of the testicular vessels; in this procedure extra length of the testicular vessel can be achieved by peeling off the peritoneum as high as possible.
3. Accidental ligation of the cord structures is avoided.
4. This technique decreases the anesthetic complications and reduces the undue stress of drugs and surgery.

CONCLUSION: In our study we also found that routine ligation of the hernial sac is not mandatory during orchidopexy. And it also reduces morbidity and operative time.

[2]*Assistant Professor, Department of General Surgery, AIMS & RC, Udaipur.*

ABSTRACT

Background: *The aim of the present study was firstly, to know about the common causes of pathological fractures, secondly, to know the epidemiology of pathological fracture with respect to age, sex, and site and thirdly to know about the various modes of treatment options available in the management of pathological fractures.*

Methods: *108 total numbers of cases were included in this study. This study was conducted in Department of Orthopedics. The duration of study was over a period of one year.*

Results: *The most common cause was Osteoporosis of pathological fractures (44.4%) followed by other. Femur was the most common site and most fractures occurred in the trochanteric region. Operative treatment was carried out in most cases.*

Conclusions: *This study concluded that pathological fractures due to primary bone diseases should be dealt on individual basis depending upon the age, location, nature of lesion and stage of lesion.*

Key words: *Osteoporosis, Pathological fracture, clinical analysis*

INTRODUCTION

A pathological fracture is considered as a fracture of an abnormal bone. Usually, the fracture happens during normal activity, as the abnormality of the bone reduces the strength of the bone and predisposes it to mechanical failure with minimal stress.[1] Tumors, osteonecrosis, metabolic diseases, apraxia, infections, and osteoporosis are some of the main reason behind pathological fractures. Bone tumors and lesions are the most common conditions.[2-8] Pathologic fractures due to neoplastic diseases are biologically different from fractures that are caused by non-neoplastic conditions such as trauma.[9] due to lack of adequate vigilance and insufficient knowledge of pathological fracture, misdiagnosis and mistreatment often occur with a high rate of 10% to 100%.[10,11] If pathological fractures resulted due to malignant bone tumors are mistreated, patients would lose opportunities of limb salvaging and their lives would be threatened. Previous studies mostly focused on the histopathology or surgical treatments of pathological fractures and have limited information about the diagnostic features of neoplastic pathological fractures.[2,3,7-18]

Therefore, the aim of the present study was firstly, to know

DOI: 10.21276/iabcr.2017.3.3.33	

to noneperative management. Similar results were found by Apostolos A. Tountas.

In this study, primary bone tumors were the second most common cause of pathological fracture accounting for 24 cases. 6 cases were due to benign bone tumors and rest cases were due to malignant bone tumors. In a retrospective study Sean P Scully (1996) revived 18 patients who sustained pathological fracture due to sarcoma. In the present study no case of sarcoma developed distant metastasis as against 33% undergoing amputation.

The third most common cause of pathological fracture in the present study was metastatic bone tumor. It was accounting for 21 cases. Similar results were found by Behr et al (20) . The most common metastasis was from breast (45%). Pain relief, restoration of function, decreased hospitalization and facilitation of nursing care was observed to be better with surgical management as compared to non-operative management. 6 case of pathological fractures due to infection was found in our study. Jenkins conducted a study on 74 patients of 70 years with fracture neck of femur evaluated by routine biochemical investigation and biopsy at the time of surgery. He found that subclinical osteomalacia is more prevalent than expected.

CONCLUSION

It can be concluded that pathological fractures due to primary bone diseases should be dealt on individual basis depending upon the age, location, nature of lesion and stage of lesion. Although the final outcome of the disease might not change yet adequate treatment of the fracture could provide the satisfactory pain relief and functional preservation for most cases. It requires regular follow-up and sometimes multiple surgical intervention in the proper management of pathological fractures. The treatment of the original condition is mandatory.

A Hospital Based Prospective Study on Acute Scrotum: Evaluation, Diagnosis, Intervention and Management

Mohan Lal Vishnoi[1], Manish[2*]

[1]Associate Professor, Department of General Surgery, AIIMS &RC, Rajsamand.
[2]Associate Professor, Department of Orthopaedics, AIIMS &RC, Rajsamand.

ABSTRACT

Background: Generally, testis is partly covered by tunica vaginalis derived from procesus vaginalis in anterior part. If testis, epididymis and distal part of spermatic cord is covered by tunica–vaginalis, torsion of the testis may occur in this serosal space. The major differential diagnoses are acute epididymitis, strangulated hernia, hematocle, hydrocle, testis tumor and idiopathic scrotal edema

Methods: This prospective study was carried out among 100 male patients between the age group of 14 to 70 years. Around 100 cases were included in our study.

Results: We observed that swelling & pain seen in every cases while fever in 48 cases, burning micturition in 30 cases, abdominal pain in 16 cases & 12 cases of trauma. All the patients treated conservatively responded well with complete recovery.

Conclusions: Our study revealed that Conservative treatment in the form of rest, scrotal support, antibiotics and analgesics is effective in cases of epididymo orchitis and idiopathic scrotal edema.

Keywords: epididymo orchitis, Conservative treatment, tunica vaginalis

INTRODUCTION

The term acute scrotum can be defined as signs and symptoms associated with local inflammation of the scrotum that appear suddenly and generally are not associated with trauma. These signs and symptoms are scrotal pain, swelling, redness and heat.[1] In other words, acute scrotum is an acute painful swelling of the scrotum or its contents accompanied by local signs and general symptoms. In children, the most common causes of acute scrotum are testicular torsion, appendix testis torsion, epididymitis, orchitis and pyocele.[2]

Spermatic cord or torsion of testis is certainly the most serious condition. It affects the scrotum[2] that requires urgent diagnosis and treatment to save the testis and avoid testicular loss, fertility problems and medicolegal issues.[1]

Testicular loss commences past twelve hours of initiation of symptoms. Testicular loss will definitely happen beyond twenty-four hours of symptoms. That is why in the absence of ancillary studies surgeons immediately explore the acute scrotum.[1]

Torsion of testis contains almost 15-40% of all acute testicular pain. This condition depends on abnormal relation of testis to scrotal tissue coverage.

Testicular scan and color doppler ultrasound are the two most commonly used preoperative studies. Testicular scans reliably reveal whether the testes have vascular flow or not but are difficult to be obtained during the night. Doppler ultrasounds are operator dependent and when done by

right testis is injured more often than the left one. The reason could be its greater propensity to be trapped against the pubis or inner thigh.[5] Testicular rupture is a tears in the tunica albuginea resulting in extrusion of the testicular contents. Speedy surgical intervention is crucial. Ruptured testis can be salvaged, if surgical repair is performed within 72 hours of testicular injury.[5] In the present study, mean time between surgery and the initial trauma was 35 hours. Sports injuries were the most common causes of significant testicular injury. All testes were salvaged, though two boys developed testicular atrophy during follow up. In the diagnosis of testis torsion, standard and Doppler ultrasound accomplishes specificity of 80%-100%.[6] Acute phase proteins can be helpful in the differentiation of acute epididymitis from other non-inflammatory causes of acute scrotum.[6] Even with mentioned diagnostic procedures, sometimes it is not possible to distinguish between TT or some other conditions that mimics clinical presentation of TT. Hence, a surgical intervention is actually a diagnostic procedure. It is always justified in any dilemma for the accuracy of diagnosis. Previously, it has been shown that there is a positive correlation between low air temperature and TT.[7-9]

In this study, TT also most commonly occurred in January. A number of boys underwent surgery in winter and summer, and the lowest number in autumn. The reason could be the relative contraction of cremasteric muscle in winter and increased physical activity in summer, mainly water sports.

CONCLUSION

It can be concluded that Conservative treatment in the form of rest, scrotal support, antibiotics and analgesics is effective in cases of epididymo orchitis and idiopathic scrotal edema. Emergency surgical exploration is beneficial in cases of torsion testis and Fournier's gangrene. Follow up of the patients is essential to find out the complications in form of sterility, development of fistulae and involvement of contralateral side at a later period.

ABSTRACT

Background: Fractures may occur due to low energy or high energy injuries. High energy injuries are more frequent cause of volar Barton's fracture.
Methods: 90 total number of cases were included in this study who attended the OPD. This study was conducted in Department of Orthopedics.
Results: In our study we were included total 90 cases of 0-60 age group. Mode of injury we were seen Fall on outstretched hand in 63 cases and Road traffic accident in rest cases. This study revealed that subject & functional result which were excellent in 18 & 27, good in 48 & 45 cases, fair in 15 & 6 cases, poor in 9& 12 cases respectively.
Conclusions: This study disclosed that maintaining anatomical reduction is key stone for satisfactory outcome. Best functional results were achieved till 6 months of treatment.

Keywords: Barton's fracture, Orthopedics, anatomical reduction

INTRODUCTION

It well known that Barton's fractures is named after the American surgeon John Rhea Barton, who first described it in 1838. It is a fracture of the distal end of the radius which involves the articular surface.[1] This fracture can be either an anterior marginal or posterior marginal fracture. These fractures may occur due to low energy or high energy injuries. High energy injuries are more frequent cause of volar Barton's fracture.[2-5] Volar Barton's fractures are different from other distal radius fractures. There is an associated radio carpal dislocation in Barton's fracture. In these type of fractures, conservative treatment is usually unsuccessful. Whereas, in other distal radius fractures, the functional outcome with conservative treatment is good. Complications like loss of reduction, malunion, nonunion, deformity, subluxation and instability are also associated with these types of fractures.[6-8] Several surgical treatment methods are reported in literature. Open reduction and internal fixation with a volar plate system have displayed good results. The main advantages of this system are reduction of articular surface and achieves immediate stability of joint leading to early mobilization of wrist and potential reduction of wrist and finger stiffness and reduction of early onset of wrist osteoarthritis.[9-11]

Fractures of the distal radius found the most common skeletal injuries. It is treated by Orthopaedic surgeons. These

Though, T-buttress plate is useful for achieving anatomical reduction, but care must be taken to avoid the complication of tendon rupture. The findings of this study showed that the scores of 27 patients were excellent, 45 patients good, and 12 patients fair.

CONCLUSION

This study analyzed 90 cases of volar Barton fracture operated by various surgeons. It can conclude that most common mode of injury was fall on outstretched hand. Anatomical and functional results were satisfactory in 80% cases fair in 13.3% cases and 6.6% cases had poor result. Complications were observed in 20% cases. Maintaining anatomical reduction is key stone for satisfactory outcome. Best functional results were achieved till 6 months of treatment.

Prevalence of Surgical Site Infections in IPD Department of Surgery: A Hospital Based Study

Mukesh Garg

Assistant Professor, Department of Surgery, Ananta Institute of Medical Sciences and Research Centre, Rajsamand

ABSTRACT

Background: *The most common causes of nosocomial infections are surgical site infections (SSIs). It is also reported that SSIs rate ranges from 2.5% to 41.9% worldwide and resulting in high morbidity and mortality.*

Methods: *This study conducted in Department of Surgery, Ananta Institute of Medical Sciences and Research Centre, Rajsamand.*

Results: *In this study, 410 cases were included, out of which 5.6% were infected post-surgery and 94.3% were non- infected. From the 5.6% cases 60.9% had mild infection and 30.4% had moderate infection and 8.7% had severe infection.*

Conclusions: *In the present study, the infection rate was higher. This high infection rate was due to the contaminated and dirty procedures where some of the patients were first seen about 2 to 3 days after development of pentonitis. It has been noted that the infection rate was higher in the emergency operative procedures in comparison to the elective procedures.*

Keywords: *Infection, wound, emergency, contaminated, moderate*

INTRODUCTION

World Health Organization (WHO) reported that hospital acquired infections are one of the major infectious diseases which are having a critical economic impact worldwide.[1] These infections affect around two million people annually all over the world.[2,3]

The most common causes of nosocomial infections are surgical site infections (SSIs). It is also reported that SSIs rate ranges from 2.5% to 41.9% worldwide and resulting in high morbidity and mortality.[4-5] Every year approximately 2% to 5% of the 16 million people develop surgical site infections while undergoing surgical procedures.[6-7] It may causes death and an economic burden on the patients due to prolonged post-operative stay in the hospitals. In developing countries, the situation is worse due to the scarcity of resources and lack of trained staff. The essential component of total quality management is to control the post-operative complications. Therefore, it is important to determine the prevalence of surgical site infections, assess the magnitude of the problem and provide a rationale to set priorities in infection control in the hospitals. In India, very few researches have been done in this direction.

Therefore, the present study had been undertaken with the following aims and objectives-

- To isolate the different organisms from post- operative wound infections.
- To determine the antibiotic sensitivity pattern of these isolates, and
- To determine the rate of SSI.

statistically significant and indicating a strong association between anemia and post-operative wound infection.

Pre-operative hospitalization has a significant effect on the post- operative wound infection. The normal bacterial flora of the patient is usually replaced by the resistant hospital flora as the duration of preoperative hospitalization increases.

In this study though the infection rate was higher when the pre- operative hospitalization was more than one week in comparison to less than one week. Though, the results are not statistically significant. Similar findings were found in the another study.[8,10]

In comparison to males (13.14%), females (15.28%) had higher infection rate but it was statistically insignificant. The small sample size of females can be held responsible for this insignificance. Infection rates were also found to be higher in cases with pre-operative hospitalization over 1 week and in cases over 60 years of age. These higher infections rates were again non - significant.

CONCLUSION

The present study suggested the effect of nature, duration and urgency of surgery along with diabetes, anemia and use of the drain as strong indicators of infection. The present study presented the changing outline of wound infection towards mixed infections.

If we get a chance, we would like to this study again with greater number of patients to get the better results and to validate our findings of the present study.

Role of Prophylactic Antibiotics and Prevalence of Post-operative Wound Infection in Surgery Department

Mukesh Garg

Assistant Professor, Department of Surgery, Ananta Institute of Medical Sciences and Research Centre, Rajsamand

ABSTRACT

Background: the Surgical Wound Infection Task Force changed the term 'surgical wound infection' with 'surgical site infection'. Surgical site infection is defined as superficial site infection and organ or space infection.
Methods: Total 100 cases were involved in this study , 50 for Group A and 50 as Group B. The case control study was carried out in the Departments of Surgery and Microbiology of Ananta Institute of Medical Sciences and Research Centre, Rajsamand. *Results:* Some associated factors were found such as Anemia Diabetes Mellitus Obesity & Prolonged duration of surgery in group A as well as group B. After post-operative surgery, we found that Staphylococcus aureus most popular organisms which causes infection followed by P. aeruginosa , K. pneumonia, Escherichia coli.
Conclusion: For surgical-site infections, surgeon should remember local and microbial factors should take appropriate measures to avoid them. One should use the most efficient and the best surgical techniques should try to avoid undue delays in the procedure to prevent postoperative wound infection.

Key words: Surgical Wound Infection, Post-operative, Staphylococcus aureus, Escherichia coli.

INTRODUCTION

Surgical wound infection is one of the most common postoperative complications. It causes significant postoperative morbidity and mortality, prolonged stay in hospital and economic burden on patients as hospital costs. Though it is difficult to eliminate the wound infection completely yet a reduction in the infection rate to a minimal level could have significant benefits for the patient and medical resources.[1] Wound infection can be considered as any purulent discharge from a closed surgical incision, together with signs of inflammation of the surrounding tissue. There are chances of the occurrences of infection at an incision site within 30 days of an operation, but wounds which are closed and primarily healed are not considered infected. In 1992, the Surgical Wound Infection Task Force changed the term 'surgical wound infection' with 'surgical site infection'. Surgical site infection is defined as superficial site infection and organ or space infection.[2] The criteria laid for wound infection by Centers for Disease Control and Prevention (CDC) and the National Nosocomial Infection System is as follows:

1. A purulent discharge from a closed surgical incision.
2. A positive culture obtained from a surgical site which was closed initially

glucose level below 200 mg/dl reduced the incidence of SSI significantly from 24% to 6.06%. In the present study, 12 cases were diabetic also.[10]

In our study, we found that 68% & 58% were male and 32% & 42% were female in group A and group B respectively. Among these cases group A had 26% of 41-50 age group & 28% of 21-30 Age in group B. Some associated factors were found such as Anemia Diabetes Mellitus Obesity & Prolonged duration of surgery in group A as well as group B. After post-operative surgery, we found that *Staphylococcus aureus* most popular organisms which causes infection followed by *P. aeruginosa, K. pneumonia, Escherichia coli.*

CONCLUSION

For effective prevention of surgical-site infections, surgeon should remember local and microbial factors should take appropriate measures to avoid them. One should use the most efficient and the best surgical techniques should try to avoid undue delays in the procedure to prevent postoperative wound infection. Prophylactic Antibiotics has been found to play a major role in preventing the post-operative wound infections.

ABSTRACT

Background: *Hepatitis B virus infection is a major global health problem and India accounts for 10-15%of the entire pool of HBV carriers of the world. Prevalence of Hepatitis B in pregnant women worldwide is 2.5 to 1.5%, whereas in India it is 2 to 7%. Hepatitis B virus is a double stranded DNA virus. The study was undertaken to determine the seroprevalence of Hepatitis B among the pregnant women in southern part of Rajasthan at a rural based tertiary care teaching hospital.* ***Methods:*** *This is a prospective study conducted at a tertiary care hospital, Udaipur, Rajasthan, from August 2015 to December 2017.Blood samples were collected from 1011 pregnant women with age ranging from 15-45 years. Screening of HBsAg was done by RPHA method and positive HBsAg tests were confirmed by ELISA. The data of those , who were found to be positive for HBsAg was statistically analyzed with the chi square tests, and results were considered significant if the p value was <0.05.*

Results: *The overall HBsAg seroprevalence rate was 1.28%, among the total 1011 pregnant women included in this study. HBsAg seroprevalence was highest, (1.64%) in 15-25 years of age group, and 1.71% in the second trimester of pregnancy. The correlations of seroprevalence rate of HBsAg among selected age groups and according to second trimester of pregnancy were not found statistically significant. (p value>0.05)*

Conclusion*: In this study the seroprevalence of Hepatitis B surface antigen was 1.28%. To prevent vertical transmission in the pregnant women, they should be screened for HBsAg at the first antenatal visit for appropriate management.*

Keywords: *Hepatitis B surface antigen, pregnant women, Vertical Transmission*

INTRODUCTION

Hepatitis B Virus (HBV) infection is one of the most common public health problems. India has over 40 million hepatitis B virus carriers accounting for 10-15% of the entire pool of HBV carriers of the world.[1,2] However, the epidemiology and pattern and consequence of HBV infection varies greatly from one part of the world to another also changes with time. Hepatitis B is caused by double stranded DNA virus belonging to hepadnaviridae family. It leads to acute hepatitis and may also have serious complications like acute and chronic hepatitis, cirrhosis and hepatocellular carcinoma.[3-5] Hepatitis B Virus infection during pregnancy, is associated with a high risk of maternal complications. Prevalence of hepatitis B in pregnant women worldwide is 2.5 to 1.5%, whereas in India is 0.2 to 7.7%[6] Ten percent of infants born to women with acute HBV infection during the first trimester of pregnancy are HBsAg positive at birth, and 80 to 90% of neonates become HBsAg positive without prophylactic therapy, if acute maternal infection develops during the third trimester of pregnancy.[7,8] Screening and evaluation of hepatitis during the pregnancy is much more important to prevent mortality of mother and child. However there is a scarcity of systematic information on the prevalence of HBV infection among pregnant women in India including the study area. This will be useful to address the current prevalence status of hepatitis B during pregnancy, the present study aimed to determine the seroprevalence of hepatitis B surface antigen among pregnant women. The risk factors of Hepatitis B infection like IV drugs, previous Blood transfusion history, previous surgeries, tattooing, piercing etc were also

evaluated, which would provide information to institutional and public measures to reduce the transmission of infection.

METHODS

The present study was undertaken over a period of one and half year from August 2015 to December 2017, approved by the institutional Ethics Committee. The present study was conducted at a rural based tertiary care teaching hospital at Udaipur district of Rajasthan. A population of 1011 pregnant women age ranging from 15-45 years attending Antenatal clinic was involved in the study. Individuals were interviewed by structured questionnaire including data regarding obstetric history, previous HBV vaccination, HBsAg status of self and spouse and the associated risk factors of infection were also asked.

Laboratory Assay: About 2 ml of venous blood was collected from each individual after obtaining a written consent under strict aseptic precautions. Rapid immunochromatography test (HEPA card) was employed to detect the presence of HBsAg. For confirmation, blood samples tested positive for HBsAg were subjected to commercially available fourth generation ELISA (Enzyme Linked Immunosorbent Assay) Kit Hepalisa by J. Mitra & Co. Pvt. Ltd with antigen sensitivity 0.1ng/ml was used. Manufacturer's instructions were followed during the entire test procedure.

RESULTS

A total of 1011 pregnant women attending antenatal clinic in a tertiary care hospital, were studied. All the women were asymptomatic and were unaware of Hepatitis B status. The subject age ranges from 15-45 years. The seroprevalence of HBsAg positivity in this current study was 1.28% among 1011 participants 13 women tested positive for HBsAg. Age distribution and HBsAg screening tests were given in Table1. In statistical analysis, the p-value obtained was >0.05 (statistically insignificant). The distribution of trimester of pregnancy and HBsAg screening results were given in Table 2. The p value obtained was >0.05 which is statistically insignificant. Analysis of age distribution of HBsAg positive women revealed a high prevalence (1.71%) among 15-25 years majority of them were primigravidae in second trimester of pregnancy. Associated risk factors distribution among HBsAg positive women was shown in Table 3.

Table 1:- Age wise distribution and HBsAg status (n=1011)

Age	Number tested	HBsAg positive	HBsAg negative
15-25	364	6(1.64%)	358 (98.35%)
26-30	384	4 (1.04%)	380 (98.95%)
31-35	208	3(1.44%)	205 (1.44%)
36-40	47	0	47(100%)
41-45	8	0	8(100%)
Total	1011	13	998

Table 2:- HBsAg seropositivity in different trimesters of pregnancy (n=1011)

Trimesters	No of Pregnant women	HBsAg positive (%)
First	243	3 (1.23%)
Second	467	8(1.71%)
Third	301	2 (0.66%)

Table-3 Risk Factors observed in HBsAg Positive women (n=13)

Risk Factors	No of ANC
History of Blood Transfusion	3(23.07%)
Previous Surgeries	2 (15.38%)
HIV status	0
Tattooing	4 (30.76%)
Piercing	13(100%)

DISCUSSION

The prevalence of HBsAg varies widely in different parts of the India. The variety of socioeconomic status of the population studied, genetic factors, and other risk factors contribute to the variance of seroprevalence rate. The prevalence of HBsAg positivity in pregnant women has been reported to range from 2.61-6.3% in various studies.[9-12] In our study, the overall seroprevalence of HBsAg positivity in pregnant women 1.28%, was in accordance with a seroprevalence of 1.1% reported by Pande et al[13] and also comparable to the seroprevalence 1.15% by Ambade et al.[14] Dwivedi et al[15] study shows the declining seroprevalence of HBsAg 0.91. Few other studies from India by Chatterjee et al[16] (0.82%) and Shazia Parveen S. et al[17](0.61%), the seroprevalence rate reported were lower than the present study. Other studies from India as carried out by Mittal et al,[18] Gill et al,[19] Nayak et al,[20] and Khakhkhar Vipul et al,[21] reported higher seroprevalence rate of 6.3%, 5%, 3.7% and 3.07% respectively in comparison of our study. Also, the seroprevalence of HBsAg among pregnant women in our study can also be comparable with 1.6%, 1.47% and 1.37% as reported in some countries respectively like Saudi Arabia,[22] Turkey[23] and Pakistan.[24] Regarding age, in the present study, high HBsAg seropositivity rate in pregnant women was found in age group of 15-25 years (1.64%) in agreement with Ambade et al, Dwivedi M et al and Khakhkhar Vipul et al, and smita Thakkarwad et al.[25] In our study highest seroprevalence of HBsAg positivity was found in second trimester 1.71%. This was with comparable studies of Padmavati Palange et al[23] and Mehta et al[26] and variance with the findings from similar works, Dwivedi M et al and Khakhkhar Vipul et al, and smita Thakkarwad et al.[25]

CONCLUSION

This study provides necessary information to detect the risk factors to formulate necessary preventive measures. The HBsAg seropositivity rate of 1.28% in pregnant women in this study recommends and supports an appropriate antenatal screening, so that the vertical transmission of Hepatitis B virus infection can be avoided. Public health policies should include routine universal screening of HBV infection and immunization of risk infants immediately after birth.

ABSTRACT

Background: *Respiratory infections among critically ill Patient are associated with high morbidity and mortality. Mechanically ventilated patients are at a high risk of acquiring respiratory infections due to complex interplay between the endotracheal tube, host immunity and virulence of invading bacteria. Irrational use of antibiotics increases the emergence of drug – resistant bacteria.* ***Objectives:*** *The aim of study was to investigate the bacterial isolates in the endotracheal aspirates of mechanically ventilated patients in ICU and see the antimicrobial resistance pattern of bacterial isolates.*

Methods: *Analysis of E.T aspirates of 459 patients over a period of 1 year (Aug 14 to Aug 15) was done. Aspirates were cultured on Blood and MacConkey agar isolation and identification was done using conventional techniques and biochemical reactions. Antibiotic sensitivity testing was done by Kirby-Bauer disc diffusion method as per CLSI guidelines.* ***Results:*** *Out of 459 Samples 365 was found to be positive. Acinetobacter sp (44.65%) was the most common isolate followed by Klebsiella sp (18.63%), Pseudomonas sp (11.23%), Candida (10.46%), Escherichia Coli (7.94%), COPS (3.28%), CONS (2.46%), Enterococci (0.82%), and Citrobacter (0.54%). The gram-negative bacilli were mostly sensitive to Tigecycline, Colistin, Imipenem, Meropenem, Amikacin and Piperacillin/Tazobactam. Gram positive Cocci were mostly sensitive to Vancomycin, Linezolid and Gentamicin.*

Conclusion*: The isolation and antimicrobial resistance pattern of the microorganisms is necessary for their effective management. Endotracheal intubation is one of the major risk factors in causing iatrogenic infections to patients. A local antibiogram for each hospital, based on bacteriological patterns and susceptibility is essential to initiate empirical therapy.*

Keywords: *Endotracheal aspirates, ventilated patients, antibiogram of bacterial isolate*

INTRODUCTION

Mechanical ventilation is a life-saving procedure for many patients in intensive care unit. Patients who are intubated and mechanically ventilated are further at a high risk of acquiring respiratory infections due to complex interplay between the endotracheal tube, host immunity and virulence of invading bacteria which may lead to ventilator associated pneumonia (VAP).Tracheal colonization of different bacteria may be responsible for added or super infections and at the same time, increases the risk of mortality[1]. The etiological agents may vary according to the population of patients in ICU, duration of hospital stay, pre-existing and prior antimicrobial therapy.

To add to the trouble, the statistical data and evidences from research prove that multi drug resistance bacteria are rapidly emerging across the world and pose a big challenge to health care system. Extensive and non-specific use of broad-spectrum antibiotics in hospitalized patients has led to both increased carriage and the development of multi drug resistant strains.[2] Multi drug resistance bacteria cause serious nosocomial and community acquired infections that are hard to eradicate. One must use existing antibiotics skillfully and more judiciously. It is difficult to manage these infections effectively unless we are armed with adequate and good quality data about the antibiotics susceptibility pattern of organisms causing respiratory infections among mechanically ventilated patients in intensive care unit. To be more effective this data has to be region specific and also

Source of Support: Nil, **Conflict of Interest:** None

has to be updated regularly as bacterial susceptibility varies with time and space. Unfortunately, such data is scanty, and this has led to a wide spread of mortality and morbidity due to respiratory infections. Therefore, updated knowledge of local epidemiology and susceptibility profile is recommended for guiding the clinicians regarding empirical choice of antibiotics and should become mandatory along with adequate clinical diagnosis and bacterial confirmation.[3]
Hence, the study was planned to identify pattern of bacterial isolates responsible for respiratory tract infections among mechanically ventilated patients at intensive care unit and to make their antimicrobial resistance pattern.

Aims & Objectives:

1. To study the microorganism's profile in the ICU during the study period in endotracheal tube culture.
2. To study the antibiotics to which these microorganisms are susceptible.
3. To propose a proper empirical antibiotic therapy in intubated patients according to prevalence of microbiological organisms in ICUs.

METHODS

The prospective study was carried out with the samples of endotracheal aspirates and endotracheal tube tip received from ICUs in the microbiology laboratory over a period of one year (Aug-2014 – Aug-2015). Samples were collected under sterile conditions from patients admitted in both medical and surgical intensive care unit who were ventilated for at least 48 hrs.

Collection of Specimen:

Endotracheal Aspirate: Sampling was done by introducing a catheter aseptically through the endotracheal tube and secretions aspirated into a sterile syringe.
Endo-tracheal tube tip: The endo-tracheal tube tip was cut aseptically into a sterile container and sent to the Microbiology laboratory.

Processing of Specimen:

Endotracheal Aspirate*:*
Both 10µl of the specimen and 1 µl of the specimen was inoculated in blood agar and MacConkey agar.
Endotracheal tube tip: The lumen of endotracheal tube tip was rinsed with 0.5 ml of sterile normal saline. 10µl of the fluid was inoculated on blood agar and MacConkey agar. A gram's stain of the endotracheal secretions / endotracheal tube tip fluid was done to assess the number of pus cells and the presence of bacteria. A semi quantitative method was followed, and plates were incubated overnight at 37°C.13. The organisms isolated were identified based on colony characteristics on Blood agar and MacConkey agar, Gram's stain, Biochemical reactions by using standard microbiological techniques. Isolates identified as commensals or contaminants were excluded from further process. A Kirby-Bauer method was used to test the susceptibility of organisms to various antibiotics. As per Clinical and Laboratory Standards guideline (2014).[4]

Antibiotics used:

Ampicillin/Sulbactam (AS-10/10µg), Cefuroxime (CXM-30µg), Cefoxitin (CX-30 µg), Ceftriaxone(CTR-30µg),Vancomycin (VA-30µg), Linezolid (LZ-30µg), Piperacillin/Tazobactam (PIT-100/10µg), Ceftazidime/Clavulanic acid (CAC-30µg/10µg), Cefotaxime/Sulbactam (CFS-5/30µg), Cefepime (CPM-5µg), Ceftriaxone (CTR-30µg),Gentamicin (GEN-10µg), Amikacin (AK-30µg), Aztreonam (AT-30µg),Azithromycin- AZM-15 µg), Ciprofloxacin (CIP-5µg), Levofloxacin-(LE5µg), Amoxicillin/Sulbactam (A/S-30µg), Imipenem (IMP-10µg), Colistin (CL-10µg), Meropenem (MRP- 10µg), Polymyxin B (PB-300U), Tigecycline (E- strip).Zone diameter was measured and interpreted as per the Clinical and Laboratory Standards Institute(CLSI) guidelines (2014)[4].

RESULTS

A total of 459 samples were collected from 459 patients during the study period of one year. Out of 459, 94 samples were either sterile or were polymicrobial growth which were not processed further for the study. Among 365, 184 samples (50.4%) were of male and rest were of female181 (49.58%). The organism isolated were *Acinetobacter sp*. 163 (44.65%), *Klebsiella sp* 68 (18.63%), *Pseudomonas sp* 41 (11.23%), *Escherichia Coli* 29 (7.94%), *Candida* 38 (10.41%), *Coagulase Positive staphylococcus aureus* (COPS)12 (3.28%), *Coagulase Negative Staphylococcus aureus* (COPS) 9 (2.46%), *Enterococci* (0.82%), and *Citrobacter* 02 (0.54%)
Acinetobacter was the most resistant of all other isolates. It was sensitive to Tigecycline (98.15%), Colistin (96.9%0, Meropenem (94.4%), Imipenem (92.02%), followed by Amikacin 36.80%, Levofloxacin 30.6%, Piperacillin/Tazobactam (25.7%), Ciprofloxacin 25.15%. (table-2).

Table 1: Micro-organisms isolated and percentage (n=459)

Micro-organisms	%
Acinetobacter sp	163(44.65%)
Klebsiella sp	68(18.63%)
Pseudomonas sp	41(11.23%)
Candida	38(10.46%)
Escherichia Coli	29(7.94%)
Citrobacter	2(0.54%)
Coagulase Negative Staphylococci (CONS)	9(2.46%)
Coagulase Positive Staphylococci (COPS)	12(3.28%)
Enterococci	3(0.82%)
No growth	94
Total	459

All isolates of Pseudomonas sp were sensitive to Imipenem 100%, Meropenem 100%, Tigecycline 100%, Colistin 100%, Polymyxin-B 100%, followed by Amikacin 68.2%, Piperacillin/ Tazobactam 68.2, Levofloxacin 56.09%. (table-2).
All Klebsiella sp were 100% sensitive to Tigecycline and Colistin followed by Imipenem 86.76%, Meropenem 88.2%, Levofloxacin 23.5%, Amikacin 35.29%, Piperacillin/Tazobactam 19.11, Ciprofloxacin 11 (16.17%). Other drugs were 7.3% sensitive were highly resistant with sensitivity of 7.3% (Ceftazidime/ C.A, Cefotaxime/ Sulbactam, Cefepime, Ceftriaxone) (table-2).
Similarly, all strains of Escherichia Coli were 100% sensitive to Tigecycline and Colistin only. Followed by Imipenem

89.6%, and Meropenem 89.6%, followed by Amikacin 79.3%, Piperacillin/ Tazobactam 68.9%, Levofloxacin 41.3%, Ciprofloxacin 34.4% (table-2.)

Only two isolates of *Citrobacter* were found which were 100% sensitive towards Amikacin, Piperacillin/Tazobactam, Imipenem, Tigecycline, Colistin, Meropenem.

In case of Gram positive bacteria all 12 (3.28%) COPS were 100% sensitive towards Vancomycin and Linezolid, followed by Gentamicin 78%, Fluoroquinolones as 41.6%, followed by Amoxicillin/Clavulanic acid and Ampicillin / Sulbactam and Cotrimoxazole 33.3%,each , other cephalosporins , (Cefuroxime, ceftizoxime, ceftriaxone, cefixime and cefoxitin) as 25% sensitive only.(Table-3)

CONS isolates were 100% sensitive towards Vancomycin and Linezolid, followed by Gentamicin 77.7%, Levofloxacin 55.5% Cotrimoxazole 33.3%) followed by other cephalosporins and Ciprofloxacin as 22.2% sensitive. (Table-3)

Enterococci show 100% sensitivity towards Vancomycin, Amoxicillin/ C.A, Ampicillin/ Sulbactam and linezolid and Gentamicin.

Table- 2 Antibiotic Sensitivity pattern of Gram-negative Clinical isolates

Organism/Antibiotics	Klebsiella sp n = 68	Acinetobacter sp n = 163	Pseudomonas sp n = 41	Escherichia Coli n = 29	Citrobacter n = 2
Amikacin	24(35.29%)	60(36.80%)	28(68.2%)	23(79.3%)	2(100%)
Piperacillin/Tazobactam	13(19.11%)	42(25.7%)	28(68.2%)	20(68.(%)	2(100%)
Ciprofloxacin	11(16.17%)	41(25.15%)	20(48.7%)	10(34.4%)	0
Levofloxacin	16(23.5%)	50(30.6%)	23(56.09%)	12(41.3%)	0
Imipenem	59(86.76%)	150(92.02%)	41(100%)	26(89.6%)	2(100%)
Tigecycline	68(100%)	160(98.15%)	41(100%)	29(100%)	2(100%)
Colistin	68(100%)	158(96.9%)	41(100%)	29(100%)	2(100%)
Meropenem	60(88.2%)	154(94.4%)	41(100%)	26(89.6%)	2(100%)
Ceftazidime/Clavulanic acid	5(7.3%)	0	18(43.9%)	9(31.03%)	0
Cefotaxime/Sulbactam	5(7.3%)	0	18(43.9%)	9(31.03%)	0
Cefepime	5(7.3%)	0	18(43.9%)	9(31.03%)	0
Ceftriaxone	5(7.3%)	0	18(43.9%)	7(24.13%)	0
Polymixin-B	ND	ND	41(100%)	ND	ND
Ampicillin/ Sulbactam	ND	ND	ND	11(37.9%)	ND

DISCUSSION

To prevent or combat respiratory failure, life- saving procedures are done on emerging or elective basis such as endotracheal intubation and mechanical ventilation. Many clinical conditions warrant need for ventilated support like life threatening infections, sepsis in acute respiratory distress syndrome, neurological dysfunction due to poisoning drug toxicity, cerebrovascular accidents, traumas and others. Mechanical Ventilation helps to prevent deaths due to respiratory failure but on the other hand it possess great threat, by host immune response and infectious organisms that lead to life threatening lung infection.[5] Mechanically ventilated and tracheotraumatized patients are colonized with bacteria of either endogenous or exogenous origin which might end up in Vat or VAP.[6] Healthcare associated infections continue to be a major cause of patient morbidity and mortality in ICUs.

The various organisms were isolated and cultured from these samples and their susceptibility testing was done according to clinical and Laboratory standard Institute guidelines (CLSI)[4] with the intention of assessing the discriminative prevalence of various common bacteria and to identify the local prevalent antibiotic response against the detected pathogens.

Table-3 Antibiotic susceptibility pattern of Gram-positive clinical isolates

Antibiotics	COPS	CONS	Enterococci
Total Strains	n = 12	n = 9	n = 3
Gentamicin	9(78%)	7 (77.77%)	3(100%)
Cefuroxime	3(25%)	2(22.2%)	0
Ceftozoxime	3(25%)	2(22.2%)	0
Ceftriaxone	3(25%)	2(22.2%)	0
Cefixime	3(25%)	2(22.2%)	0
Vancomycin	12(100%)	9(100%)	3(100%)
Azithromycin	3(25%)	2(22.2%)	0
Amoxcillin +Calvulanic Acid	4(33.3%)	2(22.2%)	3 (100%)
Ampicillin/Sulbactam	4(33.3%)	2(22.2%)	3 (100%)
Ciprofloxacin	5(41.6%)	2(22.2%)	0
Levofloxacin	5(41.6%)	5(55.5%)	0
Cotrimoxazole	4(33.3%)	3(33.3%)	0
Linezolid	12(100%)	9(100%)	3(100%)
Cefoxitin	3(25%)	2(22.2%)	0
Penicillin	2(22.2%)	5(55.5%)	0

Our study showed 80% growth from endotracheal aspirates which are concurrent with the study of Bhaskar Thakuria et al[7]. who has reported 85% growth and V.R. Rathod et al[8] who also has also reported 85% of endotracheal aspirate growth. Another study of Santosh Khanal et al[9] Ada Siler Junior et al.[10] and Koirala et al[11]have variable growth rate of (78-92%). Another Study by Kartik S.L. et. al.[12] gave a lower growth rate of 70.07%.

As far as the bacterial profile is concerned out of 365 isolates, 303 (83.47%) were gram negative bacterial isolates (GNB) and only 22 (6.06%) were GPC, similar findings has been quoted by V.S. Rathod et al[8] in which 80% were GNB, 20% were GPC. Our study correlates with many studies and particularly as shown in one systemic review article by Yaseena Arabi et al[13] were GNB range from 41 to 92%, GPC between 6-58%. In our study 38 (10.41%) isolates were fungus whose DST was not followed as our aim of study was to chart out antibiotic susceptibility profile of the bacterial isolates only.

In our study bacterial isolates identified are *Acinetobacter sp.* 44.65%, *Klebsiella sp* 18.63%, *Pseudomonas sp.* 11.23%, *Escherichia Coli* 7.94%, *Citrobacter* 0.54%,. Similar findings were reported by Priya Santharam et. al.[14] Acinetobacter followed *Pseudomonas, klebsiella pneumonia*. Non fermenter gram negative bacilli, Escherichia Coli and then *Citrbacter*. Our study also coincides with study conducted by N. Shanmuga vadivoo et. al.[15] that *Acinetobacter* has over taken the pathogenic role in ventilated patients.

V.S. rathod et al[8] quoted *Klebsiella pneumonia* as the most common isolate followed by *pseudomonas aeriginosa* and *Acinetocabter baumannii*, in his study which coincides with vadivoo et al[15] which reported *Klebsiella* followed by *Acinetobacter* and *Pseudomonas*. Also, Shilpi Dhakar et. al.[16] detected *Klebsiella* as most common pathogen followed by *Pseudomonas, staphylococcus*, *Acinetobacter* and *Escherichia Coli* with small number of *enterobacter*, and *streptococcus.* Such contrast can be due to discriminative prevalence due to the change in the demographic region of all studies conducted.

Among GPC, in our study 3.28% were COPS, 2.46% CONS and 0.821% were Enterococci isolates which is in similarity to the findings of V.S. Rathod et al [8] were GPC contributed to 6% among micro-organisms isolates. Priya Santharam et al[14] figured out 8% *Staphylococcus aureus* and were as Dipti Chandra et. al.[17] also reported 8.82% of *Staphylococcus aureus.*

In our study *Acinetobacter* was found to be the most predominant bacteria which shows high resistance towards penicillin, cephalosporins (ceftazidime and cefepime), intermediate sensitivity for aminoglycoside (Amikacin as 36.80%) followed by fluoroquinolones (Ciprofloxacin and Levofloxacin). *Acinetobacter sp* were highly sensitive towards carbapenems (Imipenem 92.02%, Meropenem 94.4%) followed by Colistin 96.9% and Tigecycline 98.15%. 40 (24.53%) strains of *Acinetobacter sp* was multidrug resistant.

Sensitivity pattern of *Klebsiella sp.* shows high resistance towards cephalosporins. Intermediate sensitivity towards Amikacin 35.29%, 23.5% for levofloxacin and 16.17% for Ciprofloxacin. Carbapenems shows 88.2% sensitivity. Most sensitive drugs against *Klebsiella sp* were Tigecycline and Colistin as 100% each. 44(64.70%) strains of *Klebsiella sp* were multi drug resistant[18]

In our study *Pseudomonas sp* shows high sensitivity pattern towards Tigecycline 100%, Colistin 100%, Meropenem 100%, Imipenem 100%, Polymixin B 100%, followed by Amikacin 68.2%, and combination Piperacillin/ Tazobactam 68.2%. Cephalosporins gave 43.9% sensitivity for pseudomonas. Flouroquinolones were also intermediate sensitive for Pseudomonas (Levofloxacin 56.09% and Ciprofloxacin 48.70 %.)

Tigecycline and Colistin were 100% sensitive for *Eschericha Coli* followed by Carbapenems (Imipenem and Meropenem 89.6% each). Amikacin has also significant sensitivity pattern for *Escherichia Coli* 79.3% followed by combination of Piperacillin/Tazobactam. Levofloxacin has lesser senstivity 41.3% and Ciprofloxacin 34.4%. All specimens show a great resistance towards cephalosporins with a sensitivity pattern of 24.13%.

Few species of *Citrobacter* were isolated which were highly sensitive towards Amikacin, Piperacillin /Tazobactam, Imipenem, Meropenem, Colistin, Tigecycline as 100% sensitive. But all were resistant towards flouroquinolones and cephalosporins.

In case of *COPS, CONS* and *Enterococci* all isolates were found 100% sensitive towards Vancomycin and Linizolid followed by Gentamicin,(78%) Flouroquinolones 41.6%, combination of Amoxicillin/C.A 33.3% /22.2% respectively and Ampicillin /Sulbactam 33.2%/ 22.2% respectively. 9 (75%) strains were identified as Methicillin resistant *Staphylococcus aureus*. Gram positive organisms of E.T. aspirates in our ICU set up were mostly resistant to penicillin derivatives and cephalosporins.

CONCLUSION

The study reveals that the antibiotic susceptibility pattern varies across region and timeline and hence studies examining the local susceptibility pattern should be carried out at every centre. Endotracheal Intubation is a major risk factor in causing iatrogenic infections to patient which leads to an increase in the morbidity and mortality. Our study reported a high percentage resistance among gram negative bacilli to cephalosporins. Aminoglycosides (Amikacin), and a combination of Piperacillin/Tazobactam were found to be moderately effective. Carbapenems, Colistin and Tigecycline were found to be most effective drug of choice.

For gram positive bacterial isolates shows significantly high resistance for penicillin and cephalosporin. 75% MRSA strains were also indentified. Vancomycin and linezolid were found to be most sensitive followed by Aminoglycoside (Gentamicin).

From present study we have concluded that analyzing the E.T aspirate was important as the sensitivity to the antibiotic obtained, is an alarming factor for efficacious and judicious use for antibiotics. This study will help us in implementing different antibiotics prophylactically with regard to the commonly obtained sensitivity pattern.

Seroprevalence of Hepatitis B Virus Infection among OPD Patients Attending Tertiary Care Hospital

Megha Sharma[1*], Shweta Bohra[1], S.K. Mehra[2], Rajeev Shah[3]

[1]Assistant Professor; [3]Associate Professor, Department of Microbiology, Ananta Institute of Medical Sciences & Research Center, Rajsamand (Rajasthan); [2]Ex- Professor & H.O.D, Department of Microbiology, Geetanjali Medical College & Hospital, Udaipur (Rajasthan)

ABSTRACT

Background: *Hepatitis B infection is a major global health problem. The hepatitis B surface antigen (HBsAg) in serum is the first seromarker to indicate active HBV infection either acute or chronic. The seroprevalence of Hepatitis B surface antigen among general population attending OPD at a tertiary care hospital is useful in assessing true nature of problem, which can help to estimate the magnitude of HBV infection and aid in devising preventive measures. The aim of the study was to determine the seroprevalence of Hepatitis B infection among OPD patients attending a tertiary care hospital.* ***Methods:*** *Data from Dec 2015- April-2017 for OPD patients underwent HBsAg screening were collected and analysed.* ***Results:*** *A total number of 3891 patients were screened for HBsAg among them 1731 (44.48%) were males and 2160 (55.51%) were females. The seroprevalence of HBsAg in total OPD patients was 90(2.31%), was higher in males 46(2.65%) as compared to females 44(2.03%). The highest seroprevalence was found in 60-71 (4%) age group.* ***Conclusions:*** *The seroprevalence of Hepatitis B positive cases was 2.31% among OPD patients. Also, the rising seroprevalence rates of hepatitis B in males need urgent attention.*

Key words: *HBsAg, seroprevalence, OPD patients, tertiary care hospital*

INTRODUCTION

About 30% of the world population has serological evidence of current or past infection with hepatitis B virus. It is known to be the 10th leading cause of death and HBV related hepatocellular carcinoma is the 5th most frequent cancer worldwide.[1] About 2 billion people (or 30% of world population) worldwide have serological evidence of current or past HBV infection, and an estimated 350 million people harbor chronic infection[2]. India has been placed into the intermediate zone of prevalence of hepatitis B (2-7% prevalence rate by WHO).[2] Indian population forms the second largest global pool of chronic HBV infections and the number of HBV carriers in India is estimated to be 50 million.[3] The virus is transmitted by either per-cutaneous or mucous membrane contact with infected blood or other body fluid and is found in highest concentrations in blood and serous exudates. The primary routes of transmission are peri-natal, early childhood exposure, sexual contact, and per cutaneous exposure to blood or body fluids (i.e. injections, needle stick, blood transfusion). The hepatitis B surface antigen (HBsAg) in serum is the first seromarker to indicate active HBV infection, either acute or chronic.[4]

A large population of patients suffering from hepatitis B may be asymptomatic and can transit the disease to healthy population. The patients presenting to the OPDs of a hospital are generally those seeking treatment for mostly community acquired ailments hence the estimation of seroprevalence of hepatitis B surface antigen in such patients can be considered as a surrogate marker to represent the dynamics of virus transmission in the community. Studies have been conducted to estimate the prevalence of hepatitis B virus in selected group of people with higher risk factors such as blood donors, pregnant women, drug addicts and patients with liver disorders.

However, there is paucity of information in India on prevalence of HBV infection among general population. That is why a prevalence based study of patients at a

tertiary care teaching hospital is helpful in assessing true nature of problem in the community, which can help in assessing the magnitude of HBV infection and aid in devising preventive measures.

Community based seroprevalence studies are difficult to conduct in a developing country like India, because of socioeconomic hurdles and logistics difficulties. More than one half ambulatory and two- thirds outpatients care are catered by private health care in India.[5]

A private tertiary teaching hospital catering to the needs of a large population thus represents an important center for serological surveys. Also, the available data at Rajasthan state level on the seroprevalence and distribution of this blood borne pathogen is limited.

It was against the above backdrop that the present study was undertaken to estimate the seroprevalence of Hepatitis B viral infection among OPD patients attending tertiary care hospital.

METHODS

The present study is a prospective hospital based study conducted in the department of Microbiology, at Ananta Institute of Medical Sciences & Research Center, Rajsamand from December 2015 to April 2017. A total of 3891 blood samples were collected from patients attending different OPDs, for whom HBsAg detection was sought after a written consent. For the evaluation of HBsAg, a one-step rapid immunochromatographic Assay (ICA) was used. The qualitative detection of HBsAg was determined using a rapid Card (Hepacard-Biomed industries). The ICA are rapid and sensitive methods for detecting HBsAg. They are economical and do not require special instrumentation for analysis and have been recommended for use in clinical microbiology laboratories.[6] Immnunochromatoghraphic Assay has high sensitivity and specificity.[7] The reactive samples were retested in duplicates with fresh blood samples, if found reactive were considered as reactive.

RESULTS

We report here a study to assess the epidemiology of HBV prevalence among the OPD patients attending a tertiary care hospital of Rajsamand (Rajasthan).

A total of 3891 serum samples were processed for HBsAg detection over a period of 12 months, among them 1731 (44.48%) were male and 2160 (55.51%) were female. Table 2 shows age and sex distribution of hospital based population. The seroprevalence of HBsAg was 90 (2.31%). It was higher in males 46 (2.65%) as compared to females 44 (2.03%). The highest seroprevalence was found to be among 61-70 age groups which were (4%). The highest seroprevalence among HBsAg positive male was found in 61-70 age group which was 5.47% and among females were in age group 41-50 which was 3.71.

DISCUSSION

The seroprevalence of HBsAg in the present study was found to be 2.31%. India has been placed into the intermediate zone of prevalence of hepatitis B (2-7%) so present study findings correspond to it. HBV prevalence among the hospital based population at Karad, Maharashtra in a tertiary care hospital by Patil et al 2016,[8] the seroprevalence of HBsAg was found to be 2.25%. A study conducted by Tripathi P.c. et al 2015[9] seroprevalence of hepatitis B surface antigen at a tertiary care center in Telangna was 1.69%. Samtha P et al 2014[10] in their hospital based population at Guntur Andhra Pradesh reported prevalence of hepatitis B surface antigen was 2.4%, which approximately coincides with our study. Quadri S.A. at al 2013[11] reported the prevalence of HBsAg to be 1.63%, in a hospital based study at Bijapur, Karnataka. A recent study conducted in Rajasthan by Payal Mathur et al 2016[12] at a tertiary care teaching hospital situated at district Ajmer, the seroprevalence of HBsAg was found to be 0.94% only. Another hospital based population study conducted by Smita Sood 2013[13] at Jaipur district of Rajasthan at a superspeciality private hospital among OPD attendees, the prevalence of hepatitis B surface antigen was observed to be 1.73%. There are several studies conducted on seroprevalence of HBsAg in India. The point of hepatitis B in non-tribal population is 3.07% and among the tribal population is 11.85%. Batham A et al in their review of 54 studies on seroprevalence of HBsAg was observed 2.4% in non-tribal population and 15.9% among tribal population. Another review of hepatitis B prevalence in India by Lodha et al has conducted that it is in between 1-2%[14]. High prevalence of HBsAg (between 2-7%) has been reported in the past, and a community based study carried out in Tamil Nadu reported the prevalence of HBsAg was 5.7%.[15] Another study conducted in Sarkhet Valley, HBsAg prevalence rate was found to be 8.8% in the hospital patients.[16] The prevalence of HBsAg in patients attending surgical OPD at Fauji Foundation hospital, Rawalpindi, Pakistan has been reported as 2.28%.[17] Seroprevalence of Hepatitis B was 2.11% to3.53%[18, 19] in Rawalpindi, and 4% from Jamshoro (Sindh).[20] Very Low prevalence rate of HBsAg also has been observed in few studies Smita Sood and Shirish Malvankar 2010[21] in a study of HBsAg prevalence in hospital based population was noted to be 0.87%. The relative low prevalence in their study could be due to the fact that it was conducted in a private hospital catering usually to economically privileged class patients. Another low prevalence of 0.62% has been reported among blood donors from coastal Karnataka.[22]

Table-1 Gender Distribution of HBsAg Positive Patients

Gender	No. of sera tested	HBsAg positive sera	Percentage
Male	1731	46	2.65
Female	2160	44	2.03

Prevalence of Hepatitis B varies from country to country and depends upon a complex mixture of behavioural, environmental and host factors. In general, it is lowest in countries or areas with high standards of living (eg. Australia, North America, North Europe) and Highest in countries or area where socioeconomic level is lower (eg. China, South-East Asia, South America)[23] Most of the studies have reported high prevalence of HBsAg in males as compared to females, which is also true in our study.

Table -2 Age and Sex distribution of OPD patients with hepatitis B seropositivity

Age Group	Male	Female	HBsAg (+) Male %	HBsAg (+) Female%	Total Patients Tested	Total Patients HBsAg (+)%
0-10	36	18	0(0%)	0(0%)	54	0(0%)
11-20	80	74	2(2.5%)	0(0%)	154	2(1.29%)
21-30	338	739	8(2.36%)	8(1.08%)	1077	16(1.48%)
31-40	392	588	8(2.04%)	14(2.38%)	980	22(2.24%)
41-50	315	296	10(3.17%)	11(3.71%)	611	21(3.43%)
51-60	352	234	9(2.55%)	8(3.41%)	586	17(2.90%)
61-70	146	129	8(5.47%)	3(2.32%)	275	11(4%)
Above 71	72	82	1(1.38%)	0(0%)	154	1(0.64%)
Total	**1731 44.48%**	**2160 55.51%**	**46 2.65%**	**44 (2.03%)**	**3891**	**90 (2.31%)**

Smita sood and Shirish Malvankar have reported the prevalence to be 1.04% and 0.58%in males and females respectively.[21] Tripathi et al reported HBsAg prevalence in males 1.97% and in 1.28% females, Payal Mathur et al reported 1.12% in males and 0.7% in female, Samtha et al reported males 2.5% and 1.13% in females. There has been no plausible explanation for the higher rates in males in the general population but probably due to the higher exposure to occupational HBV, and also probably because females clear the HBV more efficiently as compared to males. In the present study, highest prevalence was found to be among 61-70 yrs age group i.e 4% followed by 41-50 i.e. 3.43% and 51-60 age group with 2.90%. Quadari et al reported relatively higher percentage of subjects in 6^{th}, 3^{rd}, and 2^{nd} decade of life respectively were found with HBsAg in their sera. Smita Sood and Shirish Malvankar reported highest prevalence among 2^{nd}, 5^{th} and elderly patients. Patil et al reported highest HBsAg prevalence among 51-60 yrs age group (5.24%) in both males (5.51%) and females (4.78%). A community based study carried out in Tamil Nadu reported that age specific prevalence for the overall exposure to HBV, HBsAg, HBeAg was not significantly different in different age group.[24] In another population studies, conducted on blood donors the HBsAg carrier rate is observed to increased directly with age up to a peak and then to decline among the older age group.[25]

CONCLUSION

Present study reported Seroprevalence of HBsAg as well as its age and sex wise distribution, our study highlights HBV infection rate in this part of the country and shall provide reference to future studies on the epidemiology of HBV infection, to understand and assess the magnitude of disease in a community and for its control and prevention. This study also shows that the ever rising Seroprevalence rates of hepatitis B among the males, is a cause of alarm in the country which also should be taken into consideration.

ABSTRACT

Background: *Hepatitis B infection is a major global health problem. The hepatitis B surface antigen (HBsAg) in serum is the first seromarker to indicate active HBV infection either acute or chronic. The seroprevalence of Hepatitis B surface antigen among general population attending OPD at a tertiary care hospital is useful in assessing true nature of problem, which can help to estimate the magnitude of HBV infection and aid in devising preventive measures. The aim of the study was to determine the seroprevalence of Hepatitis B infection among OPD patients attending a tertiary care hospital.* ***Methods:*** *Data from Dec 2015- April-2017 for OPD patients underwent HBsAg screening were collected and analysed.* ***Results:*** *A total number of 3891 patients were screened for HBsAg among them 1731 (44.48%) were males and 2160 (55.51%) were females. The seroprevalence of HBsAg in total OPD patients was 90(2.31%), was higher in males 46(2.65%) as compared to females 44(2.03%). The highest seroprevalence was found in 60-71 (4%) age group.* ***Conclusions:*** *The seroprevalence of Hepatitis B positive cases was 2.31% among OPD patients. Also, the rising seroprevalence rates of hepatitis B in males need urgent attention.*

Key words: *HBsAg, seroprevalence, OPD patients, tertiary care hospital*

INTRODUCTION

About 30% of the world population has serological evidence of current or past infection with hepatitis B virus. It is known to be the 10th leading cause of death and HBV related hepatocellular carcinoma is the 5th most frequent cancer worldwide.[1] About 2 billion people (or 30% of world population) worldwide have serological evidence of current or past HBV infection, and an estimated 350 million people harbor chronic infection[2]. India has been placed into the intermediate zone of prevalence of hepatitis B (2-7% prevalence rate by WHO).[2] Indian population forms the second largest global pool of chronic HBV infections and the number of HBV carriers in India is estimated to be 50 million.[3] The virus is transmitted by either per-cutaneous or mucous membrane contact with infected blood or other body fluid and is found in highest concentrations in blood and serous exudates. The primary routes of transmission are peri-natal, early childhood exposure, sexual contact, and per cutaneous exposure to blood or body fluids (i.e. injections, needle stick, blood transfusion). The hepatitis B surface antigen (HBsAg) in serum is the first seromarker to indicate active HBV infection, either acute or chronic.[4]

A large population of patients suffering from hepatitis B may be asymptomatic and can transit the disease to healthy population. The patients presenting to the OPDs of a hospital are generally those seeking treatment for mostly community acquired ailments hence the estimation of seroprevalence of hepatitis B surface antigen in such patients can be considered as a surrogate marker to represent the dynamics of virus transmission in the community. Studies have been conducted to estimate the prevalence of hepatitis B virus in selected group of people with higher risk factors such as blood donors, pregnant women, drug addicts and patients with liver disorders.

However, there is paucity of information in India on prevalence of HBV infection among general population. That is why a prevalence based study of patients at a

tertiary care teaching hospital is helpful in assessing true nature of problem in the community, which can help in assessing the magnitude of HBV infection and aid in devising preventive measures.

Community based seroprevalence studies are difficult to conduct in a developing country like India, because of socioeconomic hurdles and logistics difficulties. More than one half ambulatory and two- thirds outpatients care are catered by private health care in India.[5]

A private tertiary teaching hospital catering to the needs of a large population thus represents an important center for serological surveys. Also, the available data at Rajasthan state level on the seroprevalence and distribution of this blood borne pathogen is limited.

It was against the above backdrop that the present study was undertaken to estimate the seroprevalence of Hepatitis B viral infection among OPD patients attending tertiary care hospital.

METHODS

The present study is a prospective hospital based study conducted in the department of Microbiology, at Ananta Institute of Medical Sciences & Research Center, Rajsamand from December 2015 to April 2017. A total of 3891 blood samples were collected from patients attending different OPDs, for whom HBsAg detection was sought after a written consent. For the evaluation of HBsAg, a one-step rapid immunochromatographic Assay (ICA) was used. The qualitative detection of HBsAg was determined using a rapid Card (Hepacard-Biomed industries). The ICA are rapid and sensitive methods for detecting HBsAg. They are economical and do not require special instrumentation for analysis and have been recommended for use in clinical microbiology laboratories.[6] Immnunochromatoghraphic Assay has high sensitivity and specificity.[7] The reactive samples were retested in duplicates with fresh blood samples, if found reactive were considered as reactive.

RESULTS

We report here a study to assess the epidemiology of HBV prevalence among the OPD patients attending a tertiary care hospital of Rajsamand (Rajasthan).

A total of 3891 serum samples were processed for HBsAg detection over a period of 12 months, among them 1731 (44.48%) were male and 2160 (55.51%) were female. Table 2 shows age and sex distribution of hospital based population. The seroprevalence of HBsAg was 90 (2.31%). It was higher in males 46 (2.65%) as compared to females 44 (2.03%). The highest seroprevalence was found to be among 61-70 age groups which were (4%). The highest seroprevalence among HBsAg positive male was found in 61-70 age group which was 5.47% and among females were in age group 41-50 which was 3.71.

DISCUSSION

The seroprevalence of HBsAg in the present study was found to be 2.31%. India has been placed into the intermediate zone of prevalence of hepatitis B (2-7%) so present study findings correspond to it. HBV prevalence among the hospital based population at Karad, Maharashtra in a tertiary care hospital by Patil et al 2016,[8] the seroprevalence of HBsAg was found to be 2.25%. A study conducted by Tripathi P.c. et al 2015[9] seroprevalence of hepatitis B surface antigen at a tertiary care center in Telangna was 1.69%. Samtha P et al 2014[10] in their hospital based population at Guntur Andhra Pradesh reported prevalence of hepatitis B surface antigen was 2.4%, which approximately coincides with our study. Quadri S.A. at al 2013[11] reported the prevalence of HBsAg to be 1.63%, in a hospital based study at Bijapur, Karnataka. A recent study conducted in Rajasthan by Payal Mathur et al 2016[12] at a tertiary care teaching hospital situated at district Ajmer, the seroprevalence of HBsAg was found to be 0.94% only. Another hospital based population study conducted by Smita Sood 2013[13] at Jaipur district of Rajasthan at a superspeciality private hospital among OPD attendees, the prevalence of hepatitis B surface antigen was observed to be 1.73%. There are several studies conducted on seroprevalence of HBsAg in India. The point of hepatitis B in non-tribal population is 3.07% and among the tribal population is 11.85%. Batham A et al in their review of 54 studies on seroprevalence of HBsAg was observed 2.4% in non-tribal population and 15.9% among tribal population. Another review of hepatitis B prevalence in India by Lodha et al has conducted that it is in between 1-2%[14]. High prevalence of HBsAg (between 2-7%) has been reported in the past, and a community based study carried out in Tamil Nadu reported the prevalence of HBsAg was 5.7%.[15] Another study conducted in Sarkhet Valley, HBsAg prevalence rate was found to be 8.8% in the hospital patients.[16] The prevalence of HBsAg in patients attending surgical OPD at Fauji Foundation hospital, Rawalpindi, Pakistan has been reported as 2.28%.[17] Seroprevalence of Hepatitis B was 2.11% to3.53%[18, 19] in Rawalpindi, and 4% from Jamshoro (Sindh).[20] Very Low prevalence rate of HBsAg also has been observed in few studies Smita Sood and Shirish Malvankar 2010[21] in a study of HBsAg prevalence in hospital based population was noted to be 0.87%. The relative low prevalence in their study could be due to the fact that it was conducted in a private hospital catering usually to economically privileged class patients. Another low prevalence of 0.62% has been reported among blood donors from coastal Karnataka.[22]

Table-1 Gender Distribution of HBsAg Positive Patients

Gender	No. of sera tested	HBsAg positive sera	Percentage
Male	1731	46	2.65
Female	2160	44	2.03

Prevalence of Hepatitis B varies from country to country and depends upon a complex mixture of behavioural, environmental and host factors. In general, it is lowest in countries or areas with high standards of living (eg. Australia, North America, North Europe) and Highest in countries or area where socioeconomic level is lower (eg. China, South-East Asia, South America)[23] Most of the studies have reported high prevalence of HBsAg in males as compared to females, which is also true in our study.

Table -2 Age and Sex distribution of OPD patients with hepatitis B seropositivity

Age Group	Male	Female	HBsAg (+) Male %	HBsAg (+) Female%	Total Patients Tested	Total Patients HBsAg (+)%
0-10	36	18	0(0%)	0(0%)	54	0(0%)
11-20	80	74	2(2.5%)	0(0%)	154	2(1.29%)
21-30	338	739	8(2.36%)	8(1.08%)	1077	16(1.48%)
31-40	392	588	8(2.04%)	14(2.38%)	980	22(2.24%)
41-50	315	296	10(3.17%)	11(3.71%)	611	21(3.43%)
51-60	352	234	9(2.55%)	8(3.41%)	586	17(2.90%)
61-70	146	129	8(5.47%)	3(2.32%)	275	11(4%)
Above 71	72	82	1(1.38%)	0(0%)	154	1(0.64%)
Total	**1731 44.48%**	**2160 55.51%**	**46 2.65%**	**44 (2.03%)**	**3891**	**90 (2.31%)**

Smita sood and Shirish Malvankar have reported the prevalence to be 1.04% and 0.58%in males and females respectively.[21] Tripathi et al reported HBsAg prevalence in males 1.97% and in 1.28% females, Payal Mathur et al reported 1.12% in males and 0.7% in female, Samtha et al reported males 2.5% and 1.13% in females. There has been no plausible explanation for the higher rates in males in the general population but probably due to the higher exposure to occupational HBV, and also probably because females clear the HBV more efficiently as compared to males. In the present study, highest prevalence was found to be among 61-70 yrs age group i.e 4% followed by 41-50 i.e. 3.43% and 51-60 age group with 2.90%. Quadari et al reported relatively higher percentage of subjects in 6^{th}, 3^{rd}, and 2^{nd} decade of life respectively were found with HBsAg in their sera. Smita Sood and Shirish Malvankar reported highest prevalence among 2^{nd}, 5^{th} and elderly patients. Patil et al reported highest HBsAg prevalence among 51-60 yrs age group (5.24%) in both males (5.51%) and females (4.78%). A community based study carried out in Tamil Nadu reported that age specific prevalence for the overall exposure to HBV, HBsAg, HBeAg was not significantly different in different age group.[24] In another population studies, conducted on blood donors the HBsAg carrier rate is observed to increased directly with age up to a peak and then to decline among the older age group.[25]

CONCLUSION

Present study reported Seroprevalence of HBsAg as well as its age and sex wise distribution, our study highlights HBV infection rate in this part of the country and shall provide reference to future studies on the epidemiology of HBV infection, to understand and assess the magnitude of disease in a community and for its control and prevention. This study also shows that the ever rising Seroprevalence rates of hepatitis B among the males, is a cause of alarm in the country which also should be taken into consideration.

tertiary care teaching hospital is helpful in assessing true nature of problem in the community, which can help in assessing the magnitude of HBV infection and aid in devising preventive measures.

Community based seroprevalence studies are difficult to conduct in a developing country like India, because of socioeconomic hurdles and logistics difficulties. More than one half ambulatory and two- thirds outpatients care are catered by private health care in India.[5]

A private tertiary teaching hospital catering to the needs of a large population thus represents an important center for serological surveys. Also, the available data at Rajasthan state level on the seroprevalence and distribution of this blood borne pathogen is limited.

It was against the above backdrop that the present study was undertaken to estimate the seroprevalence of Hepatitis B viral infection among OPD patients attending tertiary care hospital.

METHODS

The present study is a prospective hospital based study conducted in the department of Microbiology, at Ananta Institute of Medical Sciences & Research Center, Rajsamand from December 2015 to April 2017. A total of 3891 blood samples were collected from patients attending different OPDs, for whom HBsAg detection was sought after a written consent. For the evaluation of HBsAg, a one-step rapid immunochromatographic Assay (ICA) was used. The qualitative detection of HBsAg was determined using a rapid Card (Hepacard-Biomed industries). The ICA are rapid and sensitive methods for detecting HBsAg. They are economical and do not require special instrumentation for analysis and have been recommended for use in clinical microbiology laboratories.[6] Immnunochromatoghraphic Assay has high sensitivity and specificity.[7] The reactive samples were retested in duplicates with fresh blood samples, if found reactive were considered as reactive.

RESULTS

We report here a study to assess the epidemiology of HBV prevalence among the OPD patients attending a tertiary care hospital of Rajsamand (Rajasthan).

A total of 3891 serum samples were processed for HBsAg detection over a period of 12 months, among them 1731 (44.48%) were male and 2160 (55.51%) were female. Table 2 shows age and sex distribution of hospital based population. The seroprevalence of HBsAg was 90 (2.31%). It was higher in males 46 (2.65%) as compared to females 44 (2.03%). The highest seroprevalence was found to be among 61-70 age groups which were (4%). The highest seroprevalence among HBsAg positive male was found in 61-70 age group which was 5.47% and among females were in age group 41-50 which was 3.71.

DISCUSSION

The seroprevalence of HBsAg in the present study was found to be 2.31%. India has been placed into the intermediate zone of prevalence of hepatitis B (2-7%) so present study findings correspond to it. HBV prevalence among the hospital based population at Karad, Maharashtra in a tertiary care hospital by Patil et al 2016,[8] the seroprevalence of HBsAg was found to be 2.25%. A study conducted by Tripathi P.c. et al 2015[9] seroprevalence of hepatitis B surface antigen at a tertiary care center in Telangna was 1.69%. Samtha P et al 2014[10] in their hospital based population at Guntur Andhra Pradesh reported prevalence of hepatitis B surface antigen was 2.4%, which approximately coincides with our study. Quadri S.A. at al 2013[11] reported the prevalence of HBsAg to be 1.63%, in a hospital based study at Bijapur, Karnataka. A recent study conducted in Rajasthan by Payal Mathur et al 2016[12] at a tertiary care teaching hospital situated at district Ajmer, the seroprevalence of HBsAg was found to be 0.94% only. Another hospital based population study conducted by Smita Sood 2013[13] at Jaipur district of Rajasthan at a superspeciality private hospital among OPD attendees, the prevalence of hepatitis B surface antigen was observed to be 1.73%. There are several studies conducted on seroprevalence of HBsAg in India. The point of hepatitis B in non-tribal population is 3.07% and among the tribal population is 11.85%. Batham A et al in their review of 54 studies on seroprevalence of HBsAg was observed 2.4% in non-tribal population and 15.9% among tribal population. Another review of hepatitis B prevalence in India by Lodha et al has conducted that it is in between 1-2%[14]. High prevalence of HBsAg (between 2-7%) has been reported in the past, and a community based study carried out in Tamil Nadu reported the prevalence of HBsAg was 5.7%.[15] Another study conducted in Sarkhet Valley, HBsAg prevalence rate was found to be 8.8% in the hospital patients.[16] The prevalence of HBsAg in patients attending surgical OPD at Fauji Foundation hospital, Rawalpindi, Pakistan has been reported as 2.28%.[17] Seroprevalence of Hepatitis B was 2.11% to3.53%[18, 19] in Rawalpindi, and 4% from Jamshoro (Sindh).[20] Very Low prevalence rate of HBsAg also has been observed in few studies Smita Sood and Shirish Malvankar 2010[21] in a study of HBsAg prevalence in hospital based population was noted to be 0.87%. The relative low prevalence in their study could be due to the fact that it was conducted in a private hospital catering usually to economically privileged class patients. Another low prevalence of 0.62% has been reported among blood donors from coastal Karnataka.[22]

Table-1 Gender Distribution of HBsAg Positive Patients

Gender	No. of sera tested	HBsAg positive sera	Percentage
Male	1731	46	2.65
Female	2160	44	2.03

Prevalence of Hepatitis B varies from country to country and depends upon a complex mixture of behavioural, environmental and host factors. In general, it is lowest in countries or areas with high standards of living (eg. Australia, North America, North Europe) and Highest in countries or area where socioeconomic level is lower (eg. China, South-East Asia, South America)[23] Most of the studies have reported high prevalence of HBsAg in males as compared to females, which is also true in our study.

Smita sood and Shirish Malvankar have reported the prevalence to be 1.04% and 0.58%in males and females respectively.[21] Tripathi et al reported HBsAg prevalence in males 1.97% and in 1.28% females, Payal Mathur et al reported 1.12% in males and 0.7% in female, Samtha et al reported males 2.5% and 1.13% in females. There has been no plausible explanation for the higher rates in males in the general population but probably due to the higher exposure to occupational HBV, and also probably because females clear the HBV more efficiently as compared to males. In the present study, highest prevalence was found to be among 61-70 yrs age group i.e 4% followed by 41-50 i.e. 3.43% and 51-60 age group with 2.90%. Quadari et al reported relatively higher percentage of subjects in 6^{th}, 3^{rd}, and 2^{nd} decade of life respectively were found with HBsAg in their sera. Smita Sood and Shirish Malvankar reported highest prevalence among 2^{nd}, 5^{th} and elderly patients. Patil et al reported highest HBsAg prevalence among 51-60 yrs age group (5.24%) in both males (5.51%) and females (4.78%). A community based study carried out in Tamil Nadu reported that age specific prevalence for the overall exposure to HBV, HBsAg, HBeAg was not significantly different in different age group.[24] In another population studies, conducted on blood donors the HBsAg carrier rate is observed to increased directly with age up to a peak and then to decline among the older age group.[25]

CONCLUSION

Present study reported Seroprevalence of HBsAg as well as its age and sex wise distribution, our study highlights HBV infection rate in this part of the country and shall provide reference to future studies on the epidemiology of HBV infection, to understand and assess the magnitude of disease in a community and for its control and prevention. This study also shows that the ever rising Seroprevalence rates of hepatitis B among the males, is a cause of alarm in the country which also should be taken into consideration.

Key words:
Hepatitis B surface Antigen, ELISA and Rapid Card Test

A B S T R A C T

Background: Hepatitis B virus (HBV) is one of the major causes of death in developing countries. The most important marker for diagnosis is detection of Hepatitis B surface antigen in blood. Objective: The aim of present study was to compare two different brand rapid card test kits (Brand A and Brand B) for screening of hepatitis B virus infection with gold standard enzyme linked immunosorbent assay method. Method: This study was conducted in Department of Microbiology at government Medical College and associated hospital for a period of 6 months. Result: Out of 4200 blood samples tested for hepatitis B surface B antigen (HBsAg), 89 (2.09%) were positive by enzyme linked immunosorbent assay (ELISA), 87 (2.04%) positive by Brand A rapid card and 86 (2.02%) were positive by Brand B rapid card. The sensitivity of rapid card test Brand A was 97.75%, specificity was 100%, positive predictive value was 97.75%, negative predictive value was 99.95%, and diagnostic accuracy was 99.95%. The sensitivity of rapid card test Brand B was 96.62%, specificity was 100%, positive predictive value was 96.63%, negative predictive value was 99.93%, and diagnostic accuracy was 99.93%.Conclusion: The sensitivity and specificity of both brands rapid card test (Brand A and Brand B) is comparable with ELISA. These rapid kits are easy to perform and less cheap in compare with cost of ELISA. There use should be encourages at rural area where cannotafford the cost of ELISA test so that the patient should be channelized faster towards specific and accurate diagnosis.

INTRODUCTION

Hepatitis B virus which causes hepatocellular carcinoma is one of the important target for global elimination by 2030 [1]. The world health organization estimated that 257 million people were living with HBV infection in 2015 and responsible for 887000 deaths every year [2-3].Based on the prevalence of HBV in different areas of the world are classified as high (≥8%), Intermediate (2-7%), or low (≤2%) HBV endemicity. India has an intermediate prevalence of hepatitis B virus with a 4% to 5.4% infected population [4-5]. HBV has a double-stranded DNA genome of around 3200 base pairs encoding for P, X Core and surface proteins. The envelop proteins are surface glycoprotein and assigned as hepatitis B surface antigen [6-7]. HBsAg appears in serum within 2-10weeks after exposure to HBV and before the onset of symptoms or elevation of serum aminotransferase level. Chronic HBV infection progresses nonlinearly through 3-4 phases, from the immune-tolerance phase to immune clearance or immume-active phase to non-replicative inactive phase and possible HBsAgusually becomes undetectable after 4-6 months [8-9].

HBsAg has been found to be an important viral marker for population screening as well as diagnosis because it is the primary way to identify persons with chronic HBV infection and several characteristics of this serological marker increase the precision of HBsAg estimates, including high specificity, long serum persistence, low possibility of chronic cases losing HBsAg [10,11,12]. Early and accurate detection of HBV infection using sensitive and specific methods allow investigators to evaluate the status of HBV infection and develop strategies to prevent transmission. There are many methods for diagnosis of hepatitis B surface antigen but rapid card test is a rapid screening test for qualitative detection of HBsAg in whole blood, serum or plasma specimen. The test utilized a combination of monoclonal and polyclonal antibodies to selectively detect elevated levels of HBsAg in whole blood, serum, or plasma [8, 13]. On the other hand ELISA is enzymatic immunoassay technique of the sandwich type for the detection of HBV in human serum or plasma, in which antigens or antibodies are covalently bound with suitable enzymes that can catalyze the change of substrates into dyed products. It is an approved technique to investigate diverse serological markers [14]. The rapid immunochromatography tests are known to have less sensitivity and specificity than enzyme immunoassay [15, 16]. A major concern in utilizing rapid screening test is that these tests should have a high degree of sensitivity and a reasonable

level of specificity to minimize false positive and false negative results. The present study was designed to check the sensitivity and specificity of two different rapid cards of HBsAg which are frequently used in many labs and hospitals of Kannauj district, Uttar Pradesh, India and to compare with already confirmed cases on ELISA. The ultimate goal of this study was to recommend most reliable, specific and sensitive rapid cards for the diagnosis of HBV in areas where advance diagnostic facilities are not available.

MATERIAL AND METHOD

This prospective study was conducted in the government medical college and associated hospital at Tirwa, Kannauj, India, from November 2018- April 2019.Two most common used brands of rapid cards for HBsAg in many laboratories and hospitals were selected for the study. ELISA was used as gold standard for comparative evaluation. Prior to selection of rapid cards, a verbal survey was done in the major laboratories and hospitals to find out which brands rapid cards are being used by these outlets. For study Reckon diagnostic and SD bioline were selected.

A total of 4250HBsAg samples included 89 positive by ELISA and 4161 negative by ELISA. All samples were selected and tested on two different immunochromatography cards. As this is prospective study all samples during study period were included.

Sample collection-2-3 ml whole blood Samples were collected from patients in plain vial with clot activator and left them for 10-15 minutes at room temperature. Blood samples were then centrifuged at 1500 round per minutes for 5-10 minutes to collect serum. We used serum for performing ELISA and rapid card tests for all patients.

Sample processing- Each blood sample was tested for HBsAg using two different brands rapid card (Brand A= Reckon diagnostics pvt. LTD, Brand B= SDbioline, standard diagnostic, INC.) and ELISA by Hepalisa- J.Mitra& Co. Pvt. Ltd

Before performing the test all the samples and reagents were brought to room temperature as per kit manual.

Determination of Hepatitis B surface antigen

By Enzyme linked Immuno-sorbent assay

HEPALISA assay test kit by J. MITRA Diagnostic manufacture in India is used for ELISA technique. HEPALISA is a solid phase enzyme linked immunosorbent assay based on the 'Direct Sandwich' principle. The microwells are coated with monoclonal antibodies with high reactivity for hepatitis B surface antigen. The samples are added in the wells followed by addition of enzyme conjugate (polyclonal antibodies linked to horseradish peroxidase). A sandwiched complex is formed in the well wherein hepatitis B surface antigen (from serum samples) is trapped or "sandwiched" between the antibody and antibody horseradish peroxidase conjugate. Unbound conjugate is then washed off with wash buffer. The amount of unbound peroxidase is proportional to the concentration of HBsAg present in the sample. Upon addition of the substrate buffer &chromogen, a blue colour develops. The intensity of developed blue colour is proportional to concentration of HBsAgin sample. To limit the enzyme-substrate reaction, stop solution is added & a yellow colour develops which is finally read at 450nm spectrophotometrically.

Test Procedure: All the samples were run along with negative control (NC) and positive control (PC) according to test procedure given by manufacturer (J. Mitra Diagnostic).

Calculation of Result: Compute mean of NC and PC absorbance.

Test validity:

Positive control acceptance criteria

PC or PC$\bar{x}$ must be >0.5, if it is so, then run is invalid

Negative control acceptance criteria

NC or NC$\bar{x}$ must be <0.150

Cut off value

Cut off value is determined by using the given formula below

Cut off value = NC$\bar{x}$+0.1

Where NC$\bar{x}$ is the mean absorbance of negative control
All samples with absorbance value more than cut off value were taken as positive for hepatitis B surface antigen. The minimum detectable concentration of HBsAgby this assay is estimated to be 0.1ng/ml as per the kit used.

Determination of Hepatitis B surface antigen by Rapid card test

Rapid card (A= Reckon diagnostics pvt. LTD, B= SD diagnostic pvt. LTD)is a one -step immunoassay based on the antigen capture or sandwich principle. The method uses monoclonal antibodies conjugated to colloidal gold and polyclonal antibodies immobilized on a nitrocellulose strip in a thin line. The test sample is introduced to and to flow laterally through an absorbent pad where it mixed with the signal reagents. If the sample contains hepatitis B surface antigen, the colloidal gold-antibody conjugate binds to the antigen, forming an antigen-antibody-colloidal gold complex. The complex then migrates through the nitrocellulose strip by capillary action. When the complex meets the line of immobilized antibody (test line) 'T', complex is trapped forming an antigen-antibody colloidal gold complex. This forms a pink band indicating the sample is reactive forHBsAg.

Test procedure for both Brand's rapid card (Brand A& Brand B) as per kits

- Using the dropper provided put 2-3 drops (25µl) of serum into the sample well.
- Let the reaction to proceed until the appearance of positive line and control line or upto 20 minutes.
- Read result after 20 minutes. Strong positive reaction may visible within 5 minutes.

Interpretation of Result:		
Interpretation	Control Line	Test Line
Negative Test	Pink Line	No pink Line
Positive Test	Pink Line	Pink Line
Invalid Test	No pink Line	No pink Line/ Pink Line

Test card was stored at 4^{O}C as advised by manufacturer. The test kit was kept away from direct sunlight, moisture and heat.

RESULT

The results of different rapid cards on the basis of sensitivity, specificity, negative predictive value, positive predictive value, disease prevalence and diagnostic accuracy of Immunochromatography technique with that of ELISA which is considered as gold standard technique for the detection of HBsAg.

Out of 4250 samples, 89 (2.09%) were HBsAg positive by ELISA.
The age range of the HBsAg positive patients (n=89) was between 5-80 years with mean of 36.34±17.44 years. (Table No. 1)
Out of 89 ELISA positive samples tested on rapid card test Brand A, 87 samples were positive and 02 samples were negative for HBsAg.

On further testing on rapid card test Brand B, 86 samples were positive and 03 samples were negative for HBsAg.

The reason for false negative is unclear; this may be due to low viremia or less than 0.5ng/ml. The rapid card test (Both brands) used in this study can detect hepatitis B surface antigen in serum or plasma as low as 0.5ng/ml while HEPALISA kit has a sensitivity of 0.1ng/ml as per kit manual. For further satisfactory statement titre of hepatitis surface antigen, viral load, and other quantitative immunological markers should be perform.

On comparison with ELISA, two false negative were detected for brand A, and three false negative were detcted for brand B.

Table No. 1 Age distribution of subject (n=89) of HBsAg positive

Age Group	Subject Tested
<10	02 (2.25%)
11-20	04 4.5%)
21-30	47 (52.80%)
31-40	07 (7.87%)
41-50	11 (12.36%)
>50	18 (20.22%)
Total (n)	89 (100%)

Table No 2 Comparison of ELISA, Rapid card Brand A and Brand B

Total No of subjects	4250
Positive by ELISA	89 (2.09%)
Positive by Brand A	87 (2.04%)
Positive by Brand B	86 (2.02%)
False negative by Brand A	02 (2.24%)
False negative by Brand A	03(3.37%)

Using ELISA as a gold standard confirmatory method, comparison between ELISA and Brand A

The sensitivity of rapid card test Brand A was 97.75%, specificity was 100%, positive predictive value was 97.75%, negative predictive value was 99.95%, diagnostic accuracy was 99.95%, and disease prevalence was 2.09%. (Table No 3)

Using ELISA as a gold standard confirmatory method, comparison between ELISA and Brand B

The sensitivity of rapid card test Brand B was 96.62%, specificity was 100%, positive predictive value was 96.63%, negative predictive value was 99.93%, diagnostic accuracy was 99.99%, and disease prevalence was 2.02%. (Table No. 3)

DISCUSSION

Serological assays detect the host immune response (antibodies to HCV) or a viral antigen (HBsAg, HCVcAg). They are based on the immunoassay principle, and are available in the form of rapid diagnostic tests (RDTs) or laboratory-based enzyme immunoassays (EIAs), chemoluminescence immunoassays (CLIAs) and electrochemoluminescence immunoassays (ECLs).

In contrast, NAT technologies are typically used to detect the presence of the virus, determine if the infection is active and if the individual would benefit from antiviral treatment. NAT technologies are also used to determine when antiviral treatment should be discontinued (due to non-response or resistance) or to confirm virological cure (HCV) or effective suppression (HBV).

Most laboratory-based serological immunoassays (EIAs, CLIAs and ECLs) detect antibodies, antigens or a combination of both and differ only in the mode of detection of immune complexes formed. A cut-off value, usually determined by the manufacturer of the assay, specifies the point at which the results are considered to be reactive, and therefore, EIA results are generally reported as optical density divided by the assay cut-off (OD/CO) values.

Rapid diagnostic tests (RDTs) are single-use disposable assays that are provided in simple-to-use formats that generally require no additional reagents except those supplied in the test kit. They are read visually and can give a simple qualitative result in under 30 minutes. Quality-assured RDTs are therefore particularly useful in settings where conventional laboratory-based testing services are not available or accessible.

Table No 3 Evaluation of Rapid Card Test Brand A and Brand B with ELISA

Rapid card Brands For HBsAg		ELISA (Gold Standard)			Results for screening test									
		Reactive (n=89)	Non-reactive (n=4161)	Total	True Positive	True Negative	False Positive	False Negative	Sensitivity	Specificity	Positive Predictive Valve	Negative Predictive Value	Diagnostic accuracy	Kappa Value
Brand A (SD Bioline)	Reactive	87	-	87	87	4163	-	02	97.75%	100%	100%	99.95%	0.975	0.975
	Non-Reactive	02	4161	4163										
Brand B (Reckone)	Reactive	86	-	86	86	4164	-	03	96.62%	100%	100%	99.93%	0.975	0.975
	Non-reactive	03	4161	4164										

The choice of assay format will depend on a variety of factors, most importantly, performance characteristics (sensitivity and specificity), cost, ease of use and the characteristics of the testing site, such as storage facilities, infrastructure, and level of staff skills. WHO recommends the use of standardized testing strategies to both maximize the accuracy of HBsAg or HCV antibody testing while simplifying the process through streamlining procurement and training [17].

The choice between a one-assay versus two-assay serological testing strategy will depend on the seroprevalence in the population to be tested and diagnostic accuracy (sensitivity and specificity) of the assays used.

In many developing countries, rapid card test is widely used to detect hepatitis B surface antigen for diagnosis as well as screening for hepatitis B virus infections [18] as these are cheap and does not need expertise.

In present study, the infection rate of hepatitis B virus found to be 2.09% by ELISA test, 2.04% and 2.02% by Brand A and Brand B. A prospective study conducted in Kannauj, Uttar Pradesh, India supports our findings with infection rate of 2.28%. [19]

From the systemic review & meta-analysis on the HBsAg diagnostic accuracy of rapid cards Vs enzyme immunoassay and nucleic-acid test (NAT), three studies [20,21, 22] evaluated 7 rapid cards in samples from 510 patients against a NAT reference standard. One study [21] used plasma from Nigerian repeat blood donors. Sensitivities ranged from 38% to 99% and specificities ranged from 94% to 99%. Over all pooled sensitivity and specificity were 93.3% and 98.1% respectively.

Five studies [22,23,24,25, 26] evaluated enzyme immunoassays based on a NAT reference, using samples from 1194 patients. Pooled sensitivity and specificity were 75.7% and 86.1% respectively.

In present study we tested the serum of patientswith two differentbrands (Rapid card Brand A& Brand B) of immunochromatographic methods and subjected to compare same sere to Elisa methods.

The sensitivity of rapid card Brand A and Brand B was 100% for both with reference to ELISA and specificity was 99.95% and 99.93% respectively. Sharma M *et al* [10] reported sensitivity of rapid card was 100% and specificity was 99.56%. Another study by Akhtar *et al* [27] showed 100% sensitivity of rapid card test kit with specificity of 91.7% for hepatitis B surface antigen. A study conducted by Lin *et al* [28] by using ICTs the sensitivity and specificity was 100% respectively. A study conducted by Maity *et al* [29] a comparative study, 3 different HBsAg ICT kits Hepacard, Crystal NS SD bioline, were evaluated, all of them showing 100% sensitivity and 100% specificity. Another study shows the sensitivity of ICT can vary from 50-94% [30].Immunochromatography based assay used for HBsAg detection may not have the same accuracy indices in every region due to differences in a given population. The prevalent subtype of HBV infecting population can be different. ICT for HBsAg detection must be validated before being used in resource limited settings.

The ELISA kit that was used in this study showed to have analytical sensitivity of 0.1ng/ml and detects all the known 11 subtypes of HBV.A similar study shows that ELISA is known to detect the antigen concentration of less than 0.4 ng/ml of HBsAg while as rapid card tests based on lateral-flow technology, which appears to be most sensitive format do not achieve sensitivity of 1 IU/ml for HBsAg [15, 31]. Another study by Mubashirnazir *et al* [32] the ELISA kit that was used shows sensitivity of 0.1ng/ml.

Some studies suggest that the diagnostic performance of RDT is comparable to ELISA [33]. A study by Mizuochi. *et al* [34] shows that newly developed HBsAg rapid test had an analytical detection limit between 0.2 and 0.8 IU/ml values are similar to those of HBsAg EIAs detection.

A positive result can be followed by more accurate and advance method to confirm the infection presence unlike a negative result. In present study negative predictive value for rapid card Brand A and Brand B was 100% for both. Sensitivity and Negative predictive value are two most important parameters for choosing a test rather than specificity and positive predictive value for routine use [35].

Further work is needed as data on the circulating serotype and mutants of hepatitis B virus are widely available in India. Failure to detection hepatitis surface antigen by rapid card may be due to not proper and inadequate antigen coating, genetic heterogeneity of the virus prevalent in that area.

CONCLUSION

Results from this study indicate thatimmunochromatography based rapid card test is a simple, rapid and highly sensitive for screening for hepatitis B surface antigen. Overall performance of these rapid tests was not only compatible with currently established and advanced diagnostic methods but also cheaper. The rapid card test can be used bed site and do not need any expertise to perform and are easy to use. The ultimate goal of this study was to recommend ELISA comparable rapid device for initially screening of hepatitis B, in remote areas or where cost is an issue.

A B S T R A C T

Diabetic foot is one of the serious complications associated with diabetes and affects quality of life in respective patients in all ages and races. Diabetes mellitus is a disorder that shares the phenotype of hyperglycaemia. The prevalence of diabetes depends on many etiological factors such as age, sex, heredity, diet, socio-economic conditions and physical activity, environmental factors, life style choices etc. Diabetes is multi factorial disease in which various factors act in complex manner. A prospective study was carried out in department of microbiology at DR.B R Ambedkar Medical College & Hospital, Bangalore. Total of 120 samples with the clinical diagnosis of Diabetic Foot ulcer were collected and processed. Of the total 120 diabetic foot patients samples studied 80 were males and 40 were females, the male: female ratio being 2:1. The maximum number of patients having diabetic foot infections belonged to the age group of 56-65 years. Among the total pathogens isolated, 52.38% gram negative isolates and gram positive isolates i.e *Staphylococcus aureus* accounted for 47.62% and was the most common organism isolated, followed by *Pseudomonas aeruginosa & Klebsiella spp, Escherichia coli*.

Introduction

Diabetic foot is one of the serious complications associated with diabetes and affects quality of life in respective patients in all ages and races. Diabetes mellitus is a disorder that shares the phenotype of hyperglycaemia. The prevalence of diabetes depends on many aetiological factors such as age, sex, heredity, diet, socio-economic conditions and physical activity, environmental factors, life style choices etc. Diabetes is multi factorial disease in which various factors act in complex manner (Kasper Dennis *et al*., 2005).

Neuropathy, peripheral arterial disease, and pressure overload make the sufferers prone to ulcer. Among persons with diabetes mellitus, the risk of developing a foot ulcer is estimated to be 15%. Based on recent studies, the annual population based incidence ranges from 1.0% to 4.1% and the prevalence range from 4% to 10%, suggesting the life time incidence as high as 25% (Singh *et al*., 2005).

Patients with diabetes lose the protective sensations for temperature and pain, impairing awareness of trauma such as abrasions, blistering, or penetrating foreign body (Lipsky *et al*., 2004). Motor neuropathy can result in foot deformities that contribute to local pressure from footwear, making skin ulceration even more likely. Once the skin is

broken (typically on the plantar surface), the underlying tissues are exposed to colonization by pathogenic organisms. The resulting wound infection may begin superficially, but with delay in treatment and impaired body defense mechanisms caused by neutrophil dysfunction and vascular insufficiency, it can spread to the contiguous subcutaneous tissues and to even deeper structures (Abdulrazak *et al*., 2005). So the present study is designed to isolate and identify bacterial causes in diabetic patients and assess their susceptibility to antibiotics.

Materials and Methods

A prospective study was carried out in department of microbiology at DR.B R Ambedkar Medical College & Hospital, Bangalore, India.

Swabs obtained from diabetic foot ulcers cases during one year period from Dec 2015-Jan2017 were collected & processed. Patients details including age, sex, registration no, unit, occupation, history of trauma, habits of bare foot walking, alcohol, smoking, socio-economic status, past history of the disease and duration of the disease, treatment taken and any complications, existing co-morbidities.

E.g. Hypertension, Tuberculosis, Malnutrition, Anemia, Peripheral vascular disease were obtained

Collection of specimen*:* Discharge from margins and edges of ulcer were collected with help of two sterile swabs, one of which was used for gram stain and other for culture before antiseptic dressing was applied. Then swabs were immediately transported to the laboratory for culture.

Laboratory Procedures*:* All samples were subjected to conventional culture methods. All the samples were subjected to Gram's staining for microscopic examination and culture as per standard guidelines. The exudates were cultured on Blood agar and MacConkey agar. The specific identification of bacterial pathogens was based on microscopic morphology, staining characteristics, culture and biochemical properties using standard laboratory criteria. Antimicrobial sensitivity of the bacterial isolates was done on Mueller Hinton agar using Kirby Bauer disc diffusion method as recommended by Clinical and Laboratory Standards Institute (CLSI).

Results and Discussion

Total of 120 samples with the clinical diagnosis of Diabetic Foot ulcer were collected and processed. Out of 120 specimens, 105 (87.5%) specimens showed bacterial growth, while 15 (12.5%) specimens did not show any growth.

Of the total 120 diabetic foot patients samples studied 80 were males and 40 were females, the male: female ratio being 2:1.Age group ranged from 28 years to 70 years with an average of 55 years. The maximum number of patients having diabetic foot infections belonged to the age group of 56-65 years.

Table 2 Illustrates the bacterial isolates which shows52.38% gram negative isolates and gram positive isolates i.e *Staphylococcus aureus* accounted for 47.62% and was the most common organism isolated, followed by *Pseudomonas aeruginosa* & *Klebsiella spp, Escherichia coli.*

The Result of the test for susceptibility to the commonly used antibiotics are shown in Table no. 3, 4and 5. Antibiotic sensitivity pattern of *staphylococcus aureus* showed that Cefoxitin resistance i.e., Methicillin resistant *S.aureus (MRSA)* was 54%, combination of

Amoxycillin/Clavulanic acid showed 70% sensitivity while Gentamicin and Cefuroxime showed 65% and 50% sensitivity respectively. Erythromycin and Azithromycin showed 75% resistant pattern while Cefadroxil showed 55% resistance. Almost all isolates of *Pseudomonas aeruginosa* were sensitive to Piperacillin + Tazobactam, Cefipime and Imepenem, 80%, 76%, 100% respectively.

Foot ulceration is the most severe complication affecting diabetic patients which is not confined to certain superficial underlying subcutaneous tissue. Diabetic foot ulceration (DFU) arises from uncontrolled diabetes and incomplete health self-care (Mendes *et al*., 2012; American Diabetes Association, 2011).

This study investigates clinical and microbiological findings of DFU in patients. The majority of the patients with DFU were male and older than 50 years, consistent with other reported studies such as llanes *et al.*, (2001) which shows maximum age group above 57 years. This may be due to factors such as the differences in life styles and professional activities and jobs, causing the feet to tolerate more pressure.

In the present study, 105 organisms were isolated from 120 patients and *S.aureus* accounts for the major organism isolated. The observations are similar with Chincholikar (2002) while differ significantly from Ekta *et al.*, (2008) in which the major organism are GNB which again indicated the role of geographical variations in microbial etiology. *Staphylococcus aureus* was predominantly isolated organism (47.62%) followed by Pseudomonas *aeruginosa* (23.81%), *Klebsiella* (14.29%) and *E coli* (4.76%).

Other organisms like *Proteus mirabilis*, *P.vulgaris*, *Citrobacter spp* and *Acinetobacter spp* were also isolated. Almost similar results were obtained by Vvimalin Hena *et al.*, (2010) & Murtada Jeber *et al.*, (2013). In our study, Methicillin resistance was seen in 54% of the *S. aureus* which is also in concordance with findings by Gadepalli *et al.*, Ekta *et al.*, (2008) and Chincholikar (2002) in which MRSA was seen in 56%, 55.50% and 55.56% respectively. *Staphylococcus* spp., being the predominant organism isolated showed linezolid and teicoplanin to be the most effective antibiotics with 100% sensitivity and low resistance was seen to amoxy-clav (40%,n=50)& gentamicin (44%,n=50) but a high resistance was exhibited to other antibiotics. Other studies have shown different susceptibility antibiotic patterns and approximately in most vancomycin and linezolid have shown good activity against the strains. The antibiotic sensitivity pattern of Pseudomonas was approximately similar to study by Ekta *et al*., (2008). Most of the isolates were sensitive to almost all drugs used with Piperacilin/Tazobactam (80%:n=25),being most sensitive (80%,n=25),followed by Ceftazidime (72%,n=25), Cefepime (76%, n=25), Amikacin (64%, n=25) & low level of resistance seen to Flouroquinolones.

Table.1 Pattern of isolation of microbial growth from Diabetic Foot Ulcer

Total Patients examined	120
Patients with microbial growth n (%)	105(87.5%)
No growth n (%)	15(12.5%)
Gram Positive Isolates	47.62%
Gram Negative Isolates	52.38%

Table.2 Bacterial Pathogens isolated from 105 Culture Positive Diabetic Foot Ulcers

Organism	**Isolates**	**(n=105) (%)**
Staphylococcus aureus	50	47.62%
Pseudomonas aeruginosa	25	23.81%
Klebsiella spp	15	14.29%
Escherischia coli	5	4.76%
Proteus mirabilis	3	2.86%
Proteus vulgaris	3	2.86%
Citrobacter spp.	2	1.90%
Acinetobactor spp	2	1.90%

Table.3 Antibiogram of Staphylococcal isolates from diabetic foot ulcers (n= 50)

	(n=50)			
Anti microbial agent	S	%	R	%
Amoxycillin/Clav.acid	30	60.00%	20	40.00%
Azithromycin	15	30.00%	35	70.00%
Erythromycin	12	24.00%	38	76.00%
Cefuroxime	25	50.00%	25	50.00%
Cefoxitin sensitive	27	54.00%	23	46.00%
Cefadroxil	28	56.00%	22	44.00%
Gentamicin	28	56.00%	22	44.00%
Linezolid	45	90.00%	5	10.00%
Teicoplanin	50	100.00%	-	-

Table.4 Antimicrobial sensitivity of isolates of Pseudomonas aeruginosa (n = 25)

	n=25			
Anti microbial agent	S	%	R	%
Piperacilin/Tazobactam	20	80.00%	5	20.00%
Ceftazidime	18	72.00%	7	28.00%
Cefepime	19	76.00%	6	24.00%
Amikacin	16	64.00%	9	36.00%
Gentamicin	17	68.00%	8	32.00%
Ciprofloxacin	10	40.00%	15	60.00%
Levofloxacin	12	48.00%	13	52.00%
Doripenem	24	96.00%	1	4.00%
Imepenem	25	100.00%	0	0.00%

Table.5 Antimicrobial susceptibility pattern of gram negative bacteria except *Pseudomonas* (n = 105)

	n=105					
Anti microbial agent	*Klebsiella* spp	*Escherischia coli*	*Proteus mirabilis*	*Proteus vulgaris*	*Citrobacter* spp.	*Acinetobacter* spp
Imipenem	86.67%	80.00%	100.00%	100.00%	100.00%	100.00%
Amikacin	66.67%	60.00%	66.67%	33.33%	50.00%	50.00%
Gentamicin	73.33%	60.00%	66.67%	33.33%	100.00%	50.00%
Ciprofloxacin	46.67%	40.00%	33.33%	66.67%	50.00%	0.00%
Levofloxacin	40.00%	40.00%	33.33%	66.67%	100.00%	0.00%
Ofloxacin	40.00%	60.00%	33.33%	66.67%	100.00%	50.00%
Cefotaxime	33.33%	40.00%	66.67%	33.33%	50.00%	50.00%
Ceftriaxone	46.67%	60.00%	66.67%	33.33%	50.00%	100.00%
Cefipime	66.67%	80.00%	66.67%	66.67%	100.00%	100.00%
Co–trimoxazole	40.00%	40.00%	100.00%	66.67%	100.00%	50.00%
Ampicillin/ Sulbactam	80.00%	100.00%	66.67%	100.00%	100.00%	100.00%

All isolates were found 100% sensitivity to Imipenam. In present study, *Klebsiella* and *E. coli* were mostsensitive to combination like Ampicillin + Sulbactam, Gentamicin, Cefipime, Imepenem and these organisms were resistant to other Cephalosporins, Cotrimoxazole and Flouroquinolone. Similar results were found by Ekta *et al.,* (2008). The antibiotic resistance shown in the present study may be due to such factors including hospitalization, recent use of broad-spectrum antibiotics, history of surgery and chronic wounds, irrational use of antibiotics, and the transfer of resistance genes by transport means. To alleviate this situation and also reduce the rate of amputation, clinicians should prescribe antibiotics rationally, timely, and sufficiently and there should be periodic supervisions on the drug consumption by the respective organizations (Farshad *et al*., 2011).

It can be concluded that culture specimens for correct management of the DFI and knowledge of the susceptibility of antimicrobial drugs are essential for the choice of appropriate antibiotics with maximum efficacy. Diabetic foot infections are polymicrobial in nature

Organisms in mixed infections showed multidrug resistance as compared to single isolated strain.

These multidrug resistant organisms are frequently resistant to many classes of antibiotics so it is necessary for the clinician to be completely aware of the prevalence rate of multidrug resistant organisms and their management strategies. So this study will help the clicians to choose appropriate antibiotic or combination of antibiotics forthe treatment of Diabetic Foot Ulcer.

Abstract
Background: *Post operative infections in orthopedic implants is a major problem in orthopedic patients nowadays which can lead to implant failure and in severe cases can even lead to amputation and mortality.These are mainly associated with Open reduction and internal fixation (ORIF) of fractures with implants and prosthesis which has become the first line in the management of fractures in most traumacentres in recent times. This is also associated with high morbidity and cost for patient during his hospital stay.*
Objectives: *The objective of this paper is to isolate and identify the bacteriological isolates responsible and their antimicrobial sensitivity from post-operative orthopedic implant infections.*
Materials and Methods: *This was a prospective study carried out at a tertiary care hospital in India over a period of six months. The study was conducted on 50 cases of infected implants from orthopaedic wards, admitted in DR.B.R Ambedkar Medical College, Bangalore from 1st July to 1st December 2016.Pus samples were collected using two sterile swabs .One is used for Grams stain and other for inoculation on Mac conkey and blood agar. Susceptibility testing was performed by Kirby-Bauer disk diffusion technique.*
Results: *Out of the 50 samples processed, 40 (80%) of specimens showed culture positivity. Staphylococcus aureus 14(35%) was the predominant isolate followed by Escherichia coli 10(25%),Klebsiellaspp 8(20%), Pseudomonasspp 5(12.5%),Acinetobacterspp2(5%) and Proteus spp1 (2.5%). All Gram-positive cocci were susceptible to vancomycin and linezolid.*
Gram negative bacilli were resistant to ceftriaxone (84.6%), ciprofloxacin(69.2%), cotrimoxazole (69.2%)and sensitive to carbapenems and piperaciillintazobactam. ESBL production is seen in 11(61%) cases of Gram negative bacteria.
Pseudomonas isolates were susceptible to piperacillin-tazobactam, and meropenem.
Conclusion: *Orthopedic implant post-operative infections are a major concern in the present scenario. There is an increase incidence of multidrug resistance among the pathogens isolated from these isolates. Adequate preventive measures should be taken to prevent these antibiotic resistance amongst organisms. In this study Gram Positive Organisms has emerged as major threat for orthopedic implants.*
Key Words: *Bacterial isolates; Antibiogram; Orthop edic infection; Wounds; ESBL.*

Introduction

Infection is a major concern in orthopedic implants leading to implant failure. It is very difficult to treat orthopedic implant infections which may lead to implant failure. Sources of infection include environment of operating room, surgical equipments, clothing worn by medical and paramedical staff. Implant related infections can be due to biofilm formation also which is very common nowadays. In most of the cases removal of the infected prostheses is the ideal solution to cure these infections.

Orthopedic infections are one of the most common which can occur in approximately 1% of all orthopedic operations.[1] The most common orthopedic infections are surgical site infections (SSI) and implant infections in open or closed wounds. [2,3] Wound is a breach in the skin leading to exposure of subcutaneous tissue caused by trauma, surgeries, burns, diabetic ulcers, etc. It provides a moist, warm and nutrient environment that is conductive to microbial colonization and proliferation that leads to serious bacterial infections and death. Wound infections are one of the most common hospital-acquired infections morbidity and account for70-80% mortality.[4]

Surgical site infection (SSI) as defined by US Centers for Diseases Control (CDC) in 1992 is an infection occurring within 30 or 90 days after a surgical operation (or within 1year if an implant is left in place after procedure) and affecting either incision or deep tissues at the operation site. These infections may be superficial or deep incisional infection or infections involving organ or body space. [5]

Open or compound fractures are fractures that communicate with the outside environment through skin wounds. [6] The main causes of open fracture include road traffic accidents, fall from height, assaults, machine injury and others. Anglen JO et al reported 3-4% of all fractures are open fractures and the development of infection is favored by devitalization of bone and soft-tissue. Use of implants and prosthesis during the orthopedic surgeries can pose greater risk of microbial contamination and infection. [7]

Numerous studies have documented that gram-positive organisms are the most common bacteria causing infections associated with joint arthroplasty, with Staphylococcus aureusand Staphylococcus epidermidis causing the majority of the infections. [8,9-11] Enterococcus, Streptococcus, and gram-negative organisms such as Escherichia coli, Pseudomonas species, and Klebsiella species are less common but have been frequently reported [12]. These microorganisms can all be part of normalskin flora; hence, direct inoculation at the time of the operation as well as airborne contamination are the most likely causes of these infections. Although Staphylococcus epidermidis is generally not considered pathogenic, infections surrounding a joint replacement prosthesis may be more difficult to treat because of the bacterial biofilms typically produced by Staphylococcus aureus and Staphylococcus epidermidis around orthopaedicimplants [13,14]. This glycocalyx layer, which is formed on the surface of the orthopaedic devices, creates a complex environment for the bacteria. Numerous factors, including restricted penetration of antimicrobials into the biofilm, decreased bacterial growth rates, and expression of biofilm-specific resistance genes, all contribute to bacterial and biofilm resistance [15].

In addition to the irrational use of broad spectrum antibiotics, the changing pattern of microbial etiology and increasing challenge for both the patient and clinician.

In recent years the organisms from these infected cases are showing increased resistance to commonly used first line drugs and multi drug resistance. Methicillin resistance has become most common and also ESBL producers.

So the present study was conducted to delineate the occurrence and sensitivity pattern of such infections for a better management, thereby reducing both mortality and cost issues.

Materials and Methods

Study center

This was a prospective study carried out at a tertiary care hospital in India over a period of six months. (from 1st July to 1st December 2016).

Patient's selection

All the patients who had close fractures of long bones treated by ORIF with purulent discharge from incision or drain within a week after surgery or after few weeks after discharge from hospital of all age groups and both sexes were included into the study.

Patients with use of antibiotics after diagnosis of infection were excluded. Intra-operatively, cefuroxime (Zinacef) or Ceftriaxone (Rocephin) were used for perioperative antibiotic prophylaxis.

Processing of specimens

Swabs from open fractures, bed sores and wounds clinically suspected to be infected were collected with all aseptic precautions to avoid contamination and were immediately transported to the Microbiology laboratory. The pathogens were identified by standard laboratory procedures including gram's staining, motility, colony characters and biochemical reactions. for culture the specimens were inoculated into mac conkey and blood agar. Antibiotic susceptibility testing was done by Kirby-Bauer disc diffusion method as per CLSI guidelines[16]. Following antimicrobials were used

Table 1-The concentration of the antibiotics employed were as per CLSI guidelines .[16]

The drugs used for Gram positive organisms Were:	The drugs used for Gram negative organismswere:-
Azithromycin (AZM) 15 µg Clindamycin (CD) 2 µg Cefoxitin (CN) 30 µg Penicillin (P) 10 units Co-trimoxazole (COT) 25 µg(1.25/23.75 µg) Linezolid (LZ) 30 µg Vancomycin (VA) 30 µg Tetracycline (TE) 30 µg Levofloxacin (LE) 5 µg Gentamicin (GEN) 10 µg Gentamicin (HLG) 120 µg Erythromycin(E) 15µg Teicoplanin(TEI)30 µg Amoxyclav(AMC) 50/10 µg	Ampicillin (AMP) 10 µg Gentamicin (GEN) 10 µg Tobramycin (TOB) 10 µg Amoxycillin - Clavulanic acid (AMC) 20 µg + 10 µg Ampicillin – Sulbactam (AS) 10 µg + 10 µg Cefoxitin (CN) 30 µg Cefotaxime (CTX) 30 µg Cefepime (CPM) 30 µg Ceftazidime (CAZ) 30 µg Levofloxacin (LE) 5 µg Co-trimoxazole (COT) 25 µg Piperacillin (PC) 100 µg Piperacillin – Tazobactam (PIT) 100/10 µg Imipenem (IPM) 10 µg Meropenem (MRP) 10 µg Aztreonam (AT) 30 µg. Norfloxacin(NX)-10 µg Nitrofurantoin(NIT)-300 µg

For Pseudomonas species

Ceftazidime (30mg), gentamicin (10mg), amikacin (30mg), piperacillin/tazobactam (100mg/10mg), cefepime (30mg), cefoperazone/ sulbactam (75mg/30mg), aztreonam (30mg), ofloxacin (5mg), imipenem (10mg),ceftriaxone (30mg), netilmicin (30mg), ceftizoxime (30mg). All the antibiotic discs used were obtained from Hi-Media Laboratories Pvt. Ltd.

Detection of MRSA[17]

Inoculum was prepared by emulsifying 2-3 identical colonies in the broth. Inoculum turbidity was adjusted to 0.5 McFarland turbidity tube. A lawn culture was made on the surface of the MHA agar plate using sterile cotton swab and 30 µg Cefoxitin antibiotic disc was applied. The antimicrobial discs were obtained from Hi Media Laboratories Private Limited, Mumbai. The plates were incubated for 18-24 hours at 37 0 C. After 24

hours reading was taken and zone of inhibition was read and reported. The diameter of each zone (including the diameter of the disc) of inhibition was measured and recorded in millimeters and the result was then compared with the zone size interpretative chart.

If Zone if inhibition of cefoxitin is > 22 mm it is sensitive. If < 21 mm then reported as Methicillin Resistant. The concentration of the antibiotics employed were as per CLSI guidelines

Detection of ESBL[18]

Phenotypic Confirmatory test was followed using Cefotaxime 30 µg Cefotaxime-clavulanate 30/10 µg and Ceftazidime 30 µg Ceftazidime-clavulanate 30/10 µg. Standard Disk diffusion procedure followed and the disks were placed on MHA on which a lawn culture of the test organism was done. The plates were incubated for 18-24 hours at 37 0 C. After 24 hours reading was taken and zone of inhibition was read .A≥ 5-mm increase in a zone diameter for either antimicrobial agent tested in combination with clavulanate vs the zone diameter of the agent when tested alone=ESBL .

Results

Out of the 50 samples, 40(80%) culture were positive and 10(20%) culture were negative.

Out of 40 culture positive cases, 31 (77.5%) were males and 9(22.5%) cases were females. Out of 40 culture positives, 14 (35%)were Gram positive cocci and 26(65%) were Gram negative bacilli.

Staphylococcus aureus (35%) was the most common isolate followed by E coli(25%), Klebsiellaspp(20%) , Pseudomonasspp (12.5%), Acinetobacterspp(5%) and Proteusspp (2.5%).

Antibiogram of gram positive cocci showed highest resistance to Penicillin[100%], Amox-clav [71%], Cotrimoxazole [71%], Levofloxacin [57%] and Gentamicin[57%].Vancomycin, teicoplanin and linezolid did not show any resistance. MRSA was seen in (71.42%)% cases of Staphylococcus aureus.

About 100% of E.coli was sensitive to imipenem and 70 % sensitive to nitrofurantoin. However it was found resistant to ceftriaxone (90%), Ciprofloxacin (80%) and cotrimoxazole (80%). Among aminoglycoside, amikacin and gentamicin showed good sensitivity (70 %). Klebsiellaspp was equally sensitive (75%) to nitrofurantoin and amikacin and gentamicin (87%). Proteusspp was sensitive to most of the antibiotics. However, number of isolates was very small to draw a definitive conclusion. Proteus mirabilis was also sensitive to most of antibiotics with 100% sensitive to amikacin, cotrimoxazole and piperacillin-tazobactam.

Among E coli, 6(60%) cases were ESBL and Klebsiellaspp 5(62.5%) were ESBL.

Acinetobacter baumanii isolates were found to be highly sensitive (100%) imipenem. It was highly resistant to, ciprofloxacin (50%) and cotrimoxazole (50%). Pseudomonas aeruginosa isolates were sensitive to most of the antibiotics.

Discussion

In our study, out of 50 samples, 40 (80%) were culture positive.

This is similar to study conducted by Devi et al [19], in which out of 100 samples, 68% samples yielded growth. Among them, predominant organisms were Gram-negative bacilli with Pseudomonas (18 isolates) being most common organism with the highest sensitivity to piperacillin + tazobactam, imipenem and amikacin. Among the Gram-positive organisms isolated, S. aureus (17 isolates)

was the most common organism with maximum sensitivity to vancomycin and linezolid. Abraham Y et al [20] study which showed 41% positivity, whereas Gomez et al [21] and Zimmeli et al [22] reported positive cultures in 60% and 89% respectively.

Staphylococcus aureus was the most commonly isolated micro-organism in this study accounting for 35%. This was similar to a study conducted by Sonawane et al [23] where staphylococcus was the dominant organism (29.26%). This was similar to study conducted by Goel et al [24] 2013(32.8%).

But there are few studies where gram negative organisms were isolated the most. In a study conducted by Suneet Tandon et al [25%], Klebsiella (39.53%) was most isolated species. In our study maximum resistance is shown to penicillin among gram positive cocci which is similar to study conducted by Sonawane et al in 2010 and Jain et al 2014

In our study (71.42%) were MRSA, which does not correlate with other studies. Bergqvist et al [26] and Dan et al [27] found that 29.8% of hospitalized patients and 26.6% of hospital staff respectively are carriers. 12.5% (11/88) of our isolates are Methicillin Resistant Staphylococcus aureus. ESBL production is (61.1%) which corelates with Sonawane [23] et al 2010(71.72%).

The gram-negative aerobic rods like E.Coli, Pseudomonas, Proteus and Klebsiella were found to be sensitive to amikacin while essentially resistant to the cephalosporin tested. this was similar to study conducted by Satya Chandrika et al. [28] From our results, we observed that amoxicillin/clavulanic acid, ceftriaxone and ceftazidime cannot be recommended for use as an empirical therapy in SSI and open fracture infections because these drugs were inactive against most strains. Based on the antimicrobial susceptibility data, we suggest that piperacillin/ tazobactum and imipenem are the most effective agents against most of gram negative bacteria and vancomycin, teicoplanin and linezolid are the

most effective agents against gram positive organisms.

Conclusion

As there is high antibiotic resistance observed in our study, it is necessary for routine microbial analysis of samples and their antibiogram. Multidisciplinary collaboration with orthopedic surgeons, infectious disease specialist and clinical microbiologist is needed to reduce the incidence of orthopedic infections. There is a need for formulation of antibiotic policy and formulary restriction.

ABSTRACT

Background: The Human Immunodeficiency Virus (HIV) has changed from life threatening to chronic condition due to the almost universal use and accessibility of antiretroviral treatment (ART) among HIV patients. Antiretroviral (ARV) treatment works by suppressing the viral load and restoring the immune system. Once patients start Highly Active Antiretroviral Therapy (HAART), it is to be continued lifelong in spite of its many adverse side effects. **Objective:** To identify the adverse drug reactions (ADRs) to antiretroviral therapy (ART) and to assess their impact on treatment compliance in patients with HIV/AIDS in western India. **Methods:** A retrospective study was conducted in Gujarat to study the adverse effects after HAART initiation in 1244 patients on HAART who were evaluated retrospectively for their adverse drug reactions (ADRs). **Results:** The most common first line regimen was stavudine+lamivudine+efavirenz (d4T +3TC + EFV)(68.6 %) followed by stavudine + lamivudine + nevirapine (d4T + 3TC + NVP)(17.9%); zidovudine+ lamivudine + nevirapine(AZT+3TC+NVP) (10.9 %); and zidovudine+lamivudine+efavirenz

(AZT + 3TC +EFV) 2.5%. The first line of regimen was modified in 136(10.9%) patients, the most common cause for modifying therapy being development of an adverse effect 721(57.9%) and completion of antituberculous therapy in 510 cases(41.%). The most common cause for modifying therapy was skin rashes due to NVP in 279(22.4%) followed by loss of appetite 195(17.2%). **Conclusion:** A significant proportion of patients had adverse effects of HAART. A significant proportion of those started on NVP-based regimens are more likely to substitute therapy when compared with those on non-NVP-based regimens.

HAART - Highly Active Antiretroviral Therapy

ADR - Adverse Drug Reaction

INTRODUCTION

The Human Immunodeficiency Virus (HIV) has changed from life threatening to chronic condition due to the almost universal use and accessibility of antiretroviral treatment (ART) among HIV patients [1]. Antiretroviral (ARV) treatment works by providing suppression of viral load and restoring the immune system. It is estimated that out of the 35.3 million people living with HIV worldwide, 10.6 million were receiving ART in 2012 [2]. Nearly, 6.6 million HIV/AIDS related deaths worldwide have been prevented as a result of ART [2]. Despite these gains, adverse reactions to these medicines remain a significant public health concern and may compromise the effectiveness of the ART programmes [3,4].

In India, approximately 2.4 million people were living with human immunodeficiency virus (HIV) in 2009, which is estimated to be the third largest population of HIV affected people in the world.[5] With the availability of new antiretroviral drugs, there has been a decline in morbidity and mortality due to acquired immunodeficiency syndrome (AIDS).

The advent of highly active antiretroviral therapy (HAART) has resulted in significant decreases in HIV-related morbidity and mortality in both the developed and developing

world[6-8] and HAART has been touted as one of the greatest breakthroughs in the response to the HIV pandemic. HAART may be modified or interrupted as a result of many reasons, key among which are adverse effects and virological failure [8-11]. The adverse effects may in themselves result in virological failure or disease progression as a result of sub optimal dosing or treatment interruption.

In a study done in India, 90.6% of all the patients on HAART developed an adverse drug reaction and there were 618 episodes in various systems, the abdominal and central nervous systems were the most affected [12]. Luma and colleagues, studying patients in Cameroun found an adverse drug reaction (ADR) prevalence of 19.5% of which 21.2% were due to peripheral neuropathy. Overall 56.1% of ADR were attributed to the use of stavudine (d4T)[13]. Anaemia was observed as an ADR in many patients on ART, especially whenever the patients took zidovudine (ZDV) [14].

In an effort to scale up HAART to those who needed it most, the WHO in 2003 launched the "3 by 5" initiative with an objective of placing 3 million persons living with HIV on HAART by 2005[15]. In line with this initiative the World Health Organisation (WHO) developed guidelines on antiretroviral therapy for resource poor countries. The guidelines recommended a combination of two nucleoside reverse transcriptase inhibitors (NRTIs) and one non-nucleoside reverse transcriptase inhibitor (NNRTI) as first-line regimens in resource-constrained settings[16].

Access to antiretroviral therapy (ART) has improved tremendously over the last few years due to implementation and enforcement of various strategies by National AIDS Control Organization (NACO). NACO has established ART centres in selected government hospitals which offer free treatment for HIV/AIDS and related opportunistic infections. [17] In India, as of May 2009, there were 174 ART centres and 1,55,000 patients were on therapy. [18] By 2012, National AIDS Control Program III (2007-2012) aims to increase number of ART centres up to 250 where 3,00,000 adults will be given free ART. [17] In addition, 10 centres of excellence responsible for training, research work and mentoring of ART centres linked to them have been established across the country.[19]

HAART is the corner stone of management of patients with HIV/AIDS infection. [20] Consistent use is vital for drugs to be effective and to prevent emergence of resistance. However, ARV drugs are highly toxic and are associated with various adverse

drug reactions (ADRs) due to which many patients require withdrawal of the drug or even discontinue the treatment resulting in treatment failure. [21] Hence, monitoring and reporting of ADRs in HIV/AIDS patients receiving ART assumes great importance. There is paucity of data on ADRs to ART in Indian population. Keeping this in view, the present study was designed to identify the ADRs in patients receiving ART and to assess their impact on the compliance to the prescribed treatment.

MATERIAL AND METHODS

It was a retrospective study conducted at various ART centres of western India. The study was approved by GSACS, Ahmedabad.

A cross sectional retrospective study was conducted reviewing data of 1244 patients initiated on HAART. Univariate analysis was done for the dependent and independent variables. Stepwise logistic regression procedures were used to model the effect of gender on the development of ADRs controlling other variables like age, marital status, weight at baseline and CD4 at baseline.

From the patients records, findings of complete general, physical, systemic examination and all laboratory investigations were recorded. ADR monitoring was done in a systemic manner adopting both spontaneous and intensive monitoring approaches. The WHO definition of an ADR was adopted [22]. A pre-designed and pre-tested proforma had been confidentially used for ADR record keeping.

If the patient developed any ADR, the drug which was most commonly implicated in the causation was challenged by the treating physician and was replaced by another drug from the same class. The patient was then monitored for recovery from the symptoms.

The World Health Organisation (WHO) ADR probability scale was used for causality assessment.

With respect to ADR, following parameters were recorded.

1. Number of adverse drug reactions with different treatment regimens,
2. Nature of adverse drug reactions,
3. Severity of adverse drug reactions,

4. Incidence of each adverse drug reaction-calculated by dividing the number of patients suffereing from a particular adverse drug reaction by the total number of patients taking the same suspected drug,
5. Requirement of de-challenge,
6. Compliance to the prescribed treatment- monitored by pill count at each visit and as reported by the patient, and
7. Number of deaths.

RESULTS AND DISCUSSION

One thousand two hundred forty four (1244) patients who had been on ART were included in the present study, Out of which 1132(90.99%) patients complained of ADRs and few of them even recorded to have multiple ADRs.

Patients received four first line regimens as per the NACO guidelines [Table 1]. Stavudine +Lamivudine + Efavirenz was the most widely used combination [Table 2]. Drugs were given in the following dosages: Stavudine 40 mg B.D., Lamivudine 150 mg B.D., Nevirapine 150 mg B.D., Zidovudine 300 mg B.D. and Efavirenz 600mg H.S.

Out of the 1244 patients enrolled, 1132(90.99%) patients were recorded to report ADRs. About 74.91 % were recorded to develop more than one adverse reaction. A total of 1511 adverse drug reactions affecting various systems were observed in 1132 patients [Table 3]. Majority of adverse reactions were observed related to the gastrointestinal system and central nervous system including loss of appetite and insomnia each accounting for 28 percent. Maximum adverse reactions (872 out of 1511) were observed in patients who were prescribed treatment Ia (Stavudine + Lamivudine + Nevirapine). This was followed by 338 ADRs in patients receiving treatment regimen IIa, 223 ADRs in the patients taking treatment regimen I, and 78 ADRs in the patients taking treatment regimen II.

Irregular menstrual cycle was reported by 10 patients, 3 each in treatment I, II, and IIa. Loss of smell sensation and hearing impairment was observed in 2 patients receiving treatment regimen I and in 3 patients in regimen Ia.

Incidence of ADRs to a particular drug was calculated based on only the dechallenge test. Incidence of peripheral neuropathy and fat redistribution due to stavudine was 6.98% and

2.67%, respectively, and incidence of skin rash due to nevirapine was 7.23%, incidence of hepatitis due to nevirapine and efavirenz was 2.96% and 2.17 % respectively.

Even though HAART showed plenty of adverse drug reactions, at the same time it decreased morbidity and mortality in HIV/AIDS patients, it improved health status, body weight and even CD4 counts in almost about 90 % of the patients who adhere to this treatment strictly [Table 4].

The basic configuration of antiretroviral regimens is unchanged. The most common initial regimens are a non-nucleoside reverse transcriptase inhibitor (NNRTI) or a protease inhibitor (PI) with two nucleoside/nucleotide reverse transcriptase inhibitors (NRTIs). Common toxicities of ART can make adherence to therapy difficult. However, adherence is important to prevent the development of drug resistance. Unlike therapy for other diseases, a strategy of decreasing the dose or switching to a different drug to minimize toxicity and maximize adherence may not be possible with ART; the benefit of suppressing HIV may override other considerations. Identification and awareness of ART toxicity are necessary to facilitate patient adherence and determine when a change in therapy may be needed.

Routine monitoring in patients receiving ART includes a complete blood count and a comprehensive metabolic panel every three to six months. A lipid profile and urinalysis for proteinuria should be performed annually. When ART is changed, a complete blood count, metabolic panel, and lipid profile should be performed two to eight weeks afterward. Abnormal results should prompt more frequent testing based on clinical assessment.

According to Joint United Nations Programme on HIV and AIDS (UNAIDS) and WHO estimates, approximately 1,58,000 people all over the world were receiving ART in 2007[23]. It is well known that anti-retroviral drugs are highly toxic and therefore, early detection of ADRs by continuous monitoring is indispensable for successful treatment. In the present study, 1511 ADRs were observed in 1132 (90.99%) patients. Main risk factors associated with development of ADRs in HIV patients as determined by the researchers in previous studies included illiteracy, female gender, CD4 < 200 cells/µL, and opportunistic infections such as tuberculosis.[24] Earlier studies have also documented that a majority of ADRs were predictable and preventable.[24,25]

We observed that the maximum numbers of ADRs were related to the gastrointestinal system which is in agreement with findings of Modayil *et al*.[24] In our study, apparently maximum ADRs occurred in patients receiving stavudine+lamivudine+efavirenz which may be attributable to larger number of patients receiving this combination; however, it was observed that the incidence of ADRs was highest with the stavudine+lamivudine+nevirapine regimen.

Most cases (18/21) of peripheral neuropathy and all cases of lipodystrophy were observed in patients receiving stavudine therapy. Similar findings have been reported earlier. [24] We observed an incidence of 1.39% of peripheral neuropathy but no case of fat redistribution with stavudine. However, earlier studies have reported an incidence of peripheral neuropathy as 10%, 12% and a prevalence of lipodystrophy as 25%.[26,27.28] Low incidence seen in our study may be contributed to under diagnosis and that the drug is well tolerated in this part of the world. Recently updated WHO guidelines on ART for HIV/AIDS patients do not recommend use of stavudine as a first choice in first-line regimens due to these adverse effects.[20]

Incidence of skin rash (18.46%) and hepatotoxicity (3.19%) due to nevirapine seen in our study was almost the same when compared to that observed by Rotunda *et al*. (skin rash-15%),[29] Martinez *et al*. (hepatotoxicity-12.5%),[30] and Sulkowski *et al*. (hepatotoxicity-15.6%).[31] Latter also reported that the incidence of hepatitis due to efavirenz was 8%, whereas we found an incidence of only 0.43%. Further, in our study dechallenge with nevirapine and efavirenz in these patients resulted in resolution of hepatitis gradually over a period of 3 weeks and 1 month, respectively.

Few ADRs never documented earlier in the literature with use of ART such as irregular menstrual cycle, hearing impairment and loss of smell were also observed in the present study.

Issue of non-compliance is of major concern in management of HIV patients keeping in view that it requires lifelong treatment. Non-compliance causes significant economic implications by complicating disease management and its subsequent healthcare and social costs. Earlier studies have documented that most important factor resulting in non adherence to ART is toxicity.[32] We observed that it was mainly the severe ADRs which affected the patients' compliance. We observed that 22.1% of patients were non-compliant to ART because of

ADRs. These findings are in concordance with that of Monforte *et al.* who reported non compliance in 21.1% of Italian patients due to ADRs to ART.[32]

The risk of adverse drug reactions (ADRs) arises because of the effect of the disease on the immune systems and the safety profiles of the complex ART drugs [3]. There are a number of ADRs related to ART that have been documented, and may be mild to severe; and short to long term depending on the environment[1,5,33]. ADRs in developing countries may differ from those in developed countries because of high prevalence of conditions such as malnutrition, tuberculosis and patients presenting with advanced HIV disease [34]. For instance, it has been found that in Africa, neuropathy, neutropenia and lipodystrophy are the predominant ADRs[35]. Short term ADRs are a potential threat to successful initiation and adherence to ART[36]. The timing of ADRs may also depend on the type of drugs. Studies have shown that patients on Efavirenz, Lamivudine and Zidivudine or Indinavir, Zidovudine and Lamivudine may present with ADRs within the first 12 and 24 weeks, respectively[37]. ADRs may be common or specific to class of drugs [1,36]. Drugs classified as non-nucleoside reverse transcriptase inhibitors (NNRTIs) which include Efavirenz (EFZ) and Nevirapine (NVP) are known to cause rashes and hepatotoxicity. On the other hand, drugs classified as nucleoside reverse transcriptase inhibitors (NRTIs) including Zidovudine (AZT) and Stavudine (d4T) are known to cause anaemia, nausea, rashes, lipoatrophy and lactic acidosis.[1]

Apart from ADR depending on the environment and the type of ART regimen, a number of other risk factors have been identified, that include patient age, gender, duration of treatment, disease biomarkers such as CD4 count and viral load and body mass index (BMI) [38]. These risk factors have been found to interact with type of ADR. For instance, females are more likely to develop rashes and hepatotoxicity[38]; and patients aged 40 years and above are at a higher risk of developing peripheral neuropathy when taking d4T[39]. The longer a patient is on ART the less likely they would experience ADRs; possibly as a result of stability in ARV regimen, coming after many changes and eventually settling on an acceptable regimen [30].

Monitoring safety and toxicity related to ART remains a challenge facing the public health sector. Monitoring is usually done using spontaneous surveillance of HIV patients on treatment. Spontaneous reporting of ADRs is a very inefficient system in detecting drug-related conditions, leading to underestimation of the burden due to ADRs [3,40]. Thus, more systematic and robust surveillance methods including structured surveillance

pharmacovigilance systems, which assess and monitor safety profile and impact of antiretroviral medicines have been advocated. Structured surveillance tracks HIV positive patients who are on ART to assess drug related morbidity and mortality over time. South Africa, a country heavily hit by the HIV epidemic, uses spontaneous surveillance of HIV patients on ART to assess ART-related adverse effects. Though these data are routinely available, the coverage may not be adequate. Thus, for the purposes of this study, data from a structured surveillance system in Western India are used.

The adverse drug reaction events in patients often are of recurrent nature, such that the repetitions tend to cluster more in some patients than in others. Analyses of these data are complicated due to the fact that independence between the recurrent event times cannot be predicted in a subject. In medical studies, time-to-event models have been developed to account for possible dependence between recurrent events data [42]. The aim of this study was to provide a unified analysis of recurrent ADR events data from a structured antiretroviral pharmacovigilance surveillance system.

Table 1: Treatment Regimens as per NACO guidelines.

Treatment Regimens	Drugs in combination	No Patients
I	Zidovudine + Lamivudine + Nevirapine	136
Ia	Stavudine + Lamivudine + Nevirapine	223
II	Zidovudine + Lamivudine + Efavirenz	31
IIa	Stavudine + Lamivudine + Efavirenz	854

Table 2: Patient's characteristic in different treatment groups.

	Treatment regimen I	Treatment regimen Ia	Treatment regimen II	Treatment regimen IIa
No of patients	136	223	31	854
Mean Age(years)	36 + 8.34	40 + 2.87	33 + 7.20	38 + 4.31
Sex(M/F)	92/44	155/68	20/11	532/322
Weight (kg)	50 + 6.65	53 + 9.22	51 + 5.13	58 + 5.22
Current CD4 count				
< 200	43	78	21	247
> 200	93	145	10	607

Table 3: ADRs related to different systems.

System Involved	No. of patients with ADRs (%)
Gastrointestinal system	**678(36.45%)**
Loss of appetite	195(28.76%)
Dyspepsia	154(22.71%)
Abdominal Discomfort	81(11.94%)

Diarrhoea	74(10.91%)
Constipation	54(07.96%)
Nausea	51(07.52%)
Vomiting	43(06.34%)
Abdominal Pain	21(03.10%)
Hepatitis	05(00.59%)
Central Nervous System	**415(22.31%)**
Insomnia	111(28.75%)
Headache	89(21.45%)
Dizziness	78(18.80%)
Anxiety	57(13.73%)
Nightmare	27(06.51%)
Peripheral neuropathy	21(05.06%)
Excessive sleep at night	19(04.58%)
Delusion	14(03.37%)
Dermatological	**287(15.43%)**
Skin rashes & itching	279(97.21%)
Facial discolouration	08(02.79%)
Metabolic	**178(09.57%)**
Fatigue	109(61.24%)
Dyspnea	69(38.76%)
Musculoskeleton	**106(05.70%)**
Body ache	51(48.11%)
Vague chest pain	28(26.41%)
Pain in legs	27(25.47%)
Miscellaneous	**15(00.81%)**
Irregular menstruation	10(66.67%)
Loss of smell sensation	3(20.00%)
Hearing impairment	2(13.33%)

Table 4: Descriptive analysis of socio-demographic and health status of the patients at ART clinic.

	Variables	**n(%), N = 1244**
1	**Socio-demographic**	
(i)	Education (primary and above)	871(70.1)
(ii)	Work status (unemployed)	247 (19.9)
(iii)	Age (≤40 years)	705(56.7)
(iv)	Gender (female)	445(35.8)
(v)	Marital status (married)	1068 (85.9)
(vi)	Residency (urban)	466 (37.5)
2	**Clinical variables**	
(i)	Duration of ART (≤4 years)	495(39.8)
(ii)	Current CD4 level (cells/mm^3)	
a.	< 200	389(31.3)
b.	>200	855(68.7)
(iii)	Non adherence	47(3.8)
3	**General profile**	
	General health at the start of treatment	

(i)	Healthy	257(20.67)
(ii)	Mild to severely ill	987 (79.5)
4	**CD $_4$ count after treatment**	
(i)	Increased	1135 (91.2)
(ii)	Decreased	27(2.1)
(iii)`	No change	82(6.6)
5	**Health status after ART start**	
(i)	Improved	1114(89.5)
(ii)	Not improved	130(10.4)
6	**Body weight**	
(i)	Increased	1009(84.1)
(ii)	Decreased	91(7.3)
(iii)	No change	144(11.6)

CONCLUSION

HAART has decreased morbidity and mortality up to the expectation along with increasing considerable longevity of life of the HIV/AIDS patients. But all these antiretroviral drugs are highly toxic and associated with myriad adverse drug reactions and that too with a very high frequency. These ADRs are adding to the problem of non-compliance which in itself is a very big issue with ART. Hence, it is prudent to recognize these ADRs as early as possible in the course of treatment. This goal can be achieved by regular monitoring and reporting of ADRs which is indispensable for improving the treatment outcome.

ABSTRACT

Background: To detect the prevalence rate of bacterial infection among urinary isolates and to determine the antimicrobial susceptibility pattern in the rural area of Rajsamand. **Aim:** of the study was to find prevalence of uropathogen in this part of world along with to study the antibiogram of UTI cases. **Material and Method:** A retrospective analysis of bacterial pathogens and their antimicrobial susceptibility was done on urine sample s at tertiary care hospital. Antimicrobial susceptibility tests were done using disc diffusion technique as per the standard of Kirby-Bauer method. **Results:** Out of total 600 samples, 193 samples were found positive. Out of which males 74(38%) and females119(62%) were positive. Females showed higher prevalence rate of UTI than males. Gram negative bacteria were found in high prevalence rate than gram positive bacteria. E. coli 101(52 %) was the most common organism, followed by Klebsiella 25(13%), CoNs22(11%), Pseudomonas13(7%), CoPs11(6%), Enterococcus12(6%) Candida Sp. 6(3%) and Proteus Sp. 3(2%). **Conclusion:** There is a need for constant monitoring of susceptibility of specific pathogens in different populations to commonly used anti-microbial agents.

KEYWORDS: Urinary tract infection, Antibiotic Susceptibility Pattern, Uropathogenes.

INTRODUCTION

Urinary tract infection (UTI) is an important health-care problem affecting millions every year in the community and tertiary care settings. It is a term applied to a variety of clinical conditions ranging from asymptomatic presence of bacteria in the urine to severe of the kidney with sepsis.[1]

A count of $>10^5$ colony forming units (CFU)/mL of urine is considered as significant bacteriuria.[2] Etiological agents of UTI are variable and usually depend on time, geographical location and age of patients.[3] Most UTIs are caused by Gram-negative bacteria like Escherichia coli (E. coli), Klebsiella spp., Proteus mirabilis, Pseudomonas aeruginosa, Acinetobacter spp., and Serratia spp. and Gram-positive bacteria such as Enterococcus spp. and Staphylococcus spp[3]. E. coli is the single most common pathogen accounting for 70-75% of all cases of UTI.[2]

The antimicrobial agents used in treatment of UTI include cell wall inhibitors like Penicillin, Cephalosporins, DNA gyrase inhibitors like Floroquinolones and Aminoglycosides that are protein synthesis inhibitors. Inappropriate and extensive use of antibiotics has lead to the development of multidrug resistance among the pathogens. To ensure appropriate treatment, knowledge of the organisms that cause UTI and their antibiotic susceptibility pattern is mandatory.

MATERIAL AND METHOD

The study was conducted in a tertiary care hospital, Rajsamand, Rajasthan. All positive urine culture and sensitivity reports of males and females over a period of one year were included in the study. Urine culture and sensitivity reports with more than one causative organism were excluded from the study Sample size. The organism isolated and the antimicrobial susceptibility profiles were collected from the registration records using a standard data collection form.

Culture and Identification

As per the standard operating procedures, clean-catch midstream morning urine specimen were collected under

sterile conditions in a sterile wide mouth container. All samples were completely processed within 1–2 h after arrival, to avoid overgrowth of any contaminating bacteria. Urine samples were plated on Nutrient agar, Blood agar and MacConkey agar using calibrated wire loops and then incubated aerobically at 37 °C for 24 h. From positive cultures, uropathogens were identified based on biochemical reaction.[4]

Antimicrobial susceptibility tests

According to the standard operational procedures, antimicrobial susceptibility tests were done on Mueller-Hinton agar (Oxoid, Hampshire, England) using Kirby-Bauer disk diffusion method[8] antimicrobial agents of variable strength. Resistance data were interpreted according to Clinical laboratory Standards Institute. Reference strains of E. coli ATCC 25922 and Staphylococcus aureus ATCC 25923 (S. aureus) were used for quality control for antimicrobial susceptibility tests.[9] Statistical Analysis: Data entry was done using Microsoft Excel and the data was analysed using SPSS 16.

RESULTS

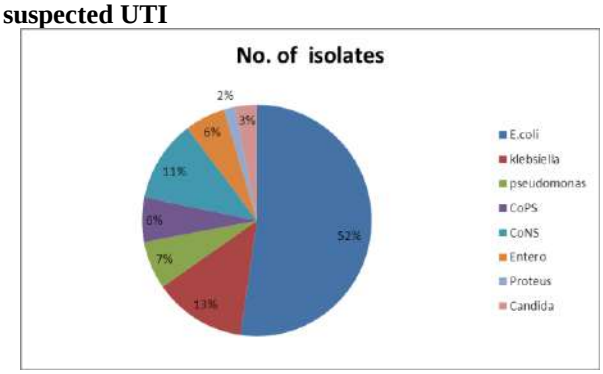
A total of 600 samples were taken during a period of 2015 -2016, out of which 193 were culture positive cases. The identification of bacteria and culture and sensitivity was carried out for the same. Out of 193 cases, males were 74 (38%) and females were 119(62%) and more common in 21-40 age group. The number of organisms isolated from females subjects were more than males (Table 1). E. coli 101(52 %) was the most common organism, followed by Klebsiella 25(13%), CoNs 22(11%), Pseudomonas 13(7%), CoPS 11(6%), Enterococcus 12(6%) Candida Sp. 6(3%) and Proteus Sp.3(2%). Sex-wise distribution of UTI by organism, Out of 74 males E. coli was isolated from 34 and Klebsiella 14 and out of 119 females E. coli was isolated from 65 and Klebsiella 11.E.coli (52%) , followed by Klebsiella (13%) were the commonest in both sexes (Table 4).The antibiotic susceptibility profile of gram negative organisms showed that E.coli and klebsiella were highly susceptible (100%) to imipenem followed by Nitrofurantoin, Amikacin, Piperacillin tazobactum, Ceftazidime/clavulanic acid while its resistance profile showed that they were more resistant to sulphamethoxazoles followed by amoxclav, ampicillin sulbactum, cephalosporins, and ceftriaxone. Staphylococcus aureus and Enterococcus were highly sensitive to Nitrofurantoin followed by Vancomycin, Linezolid, Gentamicin, Ciprofloxacin, Levofloxacin, Cotrimoxazole and Cephalosporins.

Table 1: Age and Sex distribution of patients with suspected UTI.

Age Group	Male	Female	Total
0-20	10	15	25
21-40	20	55	75
41-60	16	33	49
61-80	26	14	40
81-100	02	02	04
Total	74(38%)	119(62%)	193

Out of total 600 urine culture, 193 cases were culture Positive and sensitivity was also carried out for the same. Out of 193 cases, males were 74 (38%) and females were 119(62%) and more common in 21-40 age group. (Table.1).

Bacterial isolates from urine sample of patients with suspected UTI



E. coli 101(52 %) was the most common organism, followed by Klebsiella 25(13%), CoNs22(11%), Pseudomonas 13(7%), CoPs11(6%), Enterococcus 12(6%) Candida Sp. 6(3%) and Proteus Sp. 3(2%).

Table 2: Age- Sex distribution of patients with suspected UTI according to type of uropathogen.

Organisms	0-20		21-40		41-60		61-80		81-100		Total (n=193)
	Male	Female	Male	Female	Male	Female	Male	Female	Male	Female	
E.coli	4	9	8	26	9	20	15	9	-	1	101
Klebsiella	3	2	3	4	4	4	4	1	-	-	25
Pseudomonas	1	-	2	4	-	3	1	1	1	-	13
Proteus sp.	-	-	-	-	-	-	1	2	-	-	3
Cons	-	4	2	9	2	2	2	1	-	-	22
Cops	-	-	-	9	-	1	2	-	-	-	12
Enterococcus	2	-	4	3	-	1	-	-	1	-	11
Candida	-	-	1	-	1	2	1	-	-	1	6

According to Age-Sex distribution of Patients, Out of 74 males E. coli was isolated from 34 and Klebsiella 14 and out of 119 females E. coli was isolated from 65 and Klebsiella 11.(Table 2).

Table 3: Resistant pattern of Antibiotic in bacterial isolates from patients with suspected UTI.

Organisms	E.coli (n=101)	Klebsiella (n=(25)	Pseudo monas (n=13)	Proteus sp. (n=3)	Cons (n=22)	Cops (n=12)	Entero Coccus (n=11)
Amikacin/ Gentamycin	12 (12%)	06(24%)	03(23%)	01(33%)	NA	01(8%)	0
Cefuroxime	80(79%)	22(88%)	11(85%)	03(100%)	12(54%)	05(42%)	11(100%)
Ceftizoxime	71(70%)	20(80%)	10(77%)	02(67%)	15(68%)	05(42%)	11(100%)
Ceftriaxone	70(69%)	19(76%)	10(77%)	02(67%)	10(45%)	05(42%)	11(100%)
Ceftazidime + clavulanic acid	33(33%)	11(44%)	05(38%)	01(33%)	NA	NA	NA
Cefoperazone + sulbactam	22(22%)	11(44%)	04(30%)	01(33%)	NA	NA	NA
Cefixime	75(74%)	22(88%)	13(100%)	02(67%)	17(77%)	05(42%)	11(100%)
Vancomycin	NA	NA	NA	NA	0	0	0
Azithromycin	NA	NA	NA	NA	13(33%)	04(33%)	09(81%)
Amoxycillin + clavulanic acid	84(83%)	22(88%)	13(100%)	03(100%)	10(45%)	05(42%)	07(63%)
Ampicillin + Sulbactam	73(72%)	18(72%)	13(100%)	03(100%)	08(36%)	05(42%)	07(63%)
Piperacillin + tazobactam	18(18%)	07(28%)	05(38%)	01(33%)	NA	NA	NA
Ciprofloxacin	63(62%)	14(56%)	07(54%)	01(33%)	08(36%)	01(8%)	08(73%)
Levofloxacin	51(50 %)	13(52%)	07(54%)	01(33%)	07(32%)	0	08(73%)
Co trimoxazole	78(77%)	17(68%)	13(100%)	03(100%)	13(33%)	04(33%)	08(73%)
Linezolid	NA	NA	NA	NA	0	0	0
Aztreonam	61(60%)	19(76%)	10(77%)	02(67%)	NA	NA	NA
Imipenam	02(2%)	0	0	0	NA	NA	NA
Meropenam	02(2%)	0	0	0	NA	NA	NA
Nitrofurantoin	04(4%)	06(24%)	13(100%)	03(100%)	03(14%)	0	01(9%)
Clindamycin	NA	NA	NA	NA	11(50%)	0	NA

The overall susceptibility profiles of bacterial isolates are shown in Table 3. Amongst gram negative bacilli, amox-clav and cefuroxime had the highest overall resistance followed by Ampicillin -Sulbactam, Cefixime, Ceftizoxime, Co trimoxazole whereas other drugs showed sensitive pattern. Cephalosporins were most resistant drugs in gram positive bacilli followed by amox-clav, Azithromycin, Ampicillin- Sulbactam, Co trimoxazole, Ciprofloxacin, Levofloxacin, Clindamycin, Nitrofurantoin.

DISCUSSION

Urinary tract infection is huge burden on health care due to high prevalence of infection in both community and nosocomial settings. It is caused by variety of pathogens including *E. coli*, *K. pneumoniae* and *P. aeruginosa*. Continuous surveillance of antibiotic susceptibility patterns of uropathogens at local level is crucial in dealing with emerging problems of antibiotic resistance and provides assistance in managing effective initial therapy.[4] In present study, the prevalence of UTI in females is higher than the males which is attributed to factors like close proximity of the uretheral meatus to the anus, shorter urethra. This finding is consistent with other studies done by Jubina Bency et al Prakasam A., K.C et al and Azra S. Akram T et al. There was significant growth of E.Coli, Klebsiella, Enterococci, Staphylococcus and Pseudomonas. Ecoli & Klebsiella infections were most common organisms similar to Jubina Bency et al. *Enterococcus* was sensitive to Vancomycin & Linezolid. *Staphylococcus* was sensitive to Vancomycin.[6] The pattern of antimicrobial resistance of the micro-organisms causing UTIs vary in their susceptibility to antimicrobials from place to place and from time to time. World wide data shows that there is an increasing resistance among UTI pathogens to convential drugs. Resistance has emerged even to newer more potent antimicrobial agents.

E.coli(52 %) was the most common organism, followed by Klebsiella(13%), CoNs(11%), Pseudomonas(7%), CoPs(6%), Enterococcus(6%) Candida Sp. (3%) and Proteus Sp.(2%). This finding patterns were similar with the study of Savitha like E.coli(48.04%), Klebsiella species(8.82%) and Proteus spp.(4.90%).

It has been observed that there is slow but persistent decrease in the sensitivity of gram negative and gram positive bacteria to some quinolones derivative, Ampicillin and Sulphonamides which is alarming because these antibiotics have been one of the best options for treatment of UTI in both outdoor patients and hospitalized patients. Other factors which may influence

the sensitivity of urinary pathogens includes, routes of administration, dosage schedule, choice of antibiotic, misuse of antibiotic and condition of patients and self-medication.[7]

CONCLUSION

In this study, higher prevalence rates of urinary bacterial isolates are observed in females the most commonly found organisms were *E. coli* and *Klebsiella*. There is an emerging resistance of commonly isolated bacteria to routinely used antibiotics, which can be ascribed to inappropriate antibiotic administration. Important infecting organisms are found to be the commensals of perianal and vaginal regions, emphasizing a need to have proper hygienic practices.

ABSTRACT

Background: Bacteria associated with blood stream infections are an important public health problem which results in morbidity and mortality globally. Emergence of multidrug resistant isolates in hospitalized patients is a major problem. Automation techniques play a major role in early identification of the isolate and its drug susceptibility testing which is important for better outcome of the treatment. This study was aimed to detect the blood stream isolates and their drug susceptibility pattern in hospitalized patients.
Methods: This was a retrospective study conducted from 377 records of automated blood culture (bact/alert) and drug susceptibility testing (vitek) results. Positive blood culture bottles were sub cultured to different culture media and the isolates were identified and screened for drug susceptibility testing on Vitek II.
Results: Around 20.68% of samples were positive for blood stream infections caused by different pathogens. A total of 78 microorganisms were isolated from 377 samples. Among which gram negative bacilli was observed in 52.56%, gram positive cocci in 44.87% and yeast in 2.56% samples. Coagulase negative *staphylococci* and *Klebsiella pneumoniae* were the predominant isolates of the study.
Conclusions: Early diagnosis of blood stream infections in hospitalized patients is life saving. Hence a continuous monitoring of isolates and their drug susceptibility is the need of the day.

Keywords: Blood stream infections, Coagulase negative *staphylococcus, Klebsiella pneumoniae*

INTRODUCTION

Blood stream infection (BSI) remains one of the foremost important causes of morbidity and mortality globally. The infection may range from self limiting to life threatening sepsis.[1,2] As case fatality rate is high it requires appropriate and immediate antimicrobial therapy. Different bacteria were associated with (BSI) from time to time at different geographical areas. These bacteria play an important role in causing mortality, increasing the length of hospital stay and also the health care cost.[3]

Drug resistance of these bacteria is an important issue of public health concern. Since many studies have reported that gram negative and gram positive bacteria are associates with these infections which are often drug resistant. Empirical antibiotic therapy is initiated in almost all cases before the blood culture reports are available. Choice of right empirical therapy is important. An early blood culture report may help in selection of appropriate antibiotics.[2,4]

Minimal time is required to get a blood culture report using automated systems. The etiology and antimicrobial pattern of (BSI) may vary at different times in the same region hence a continuous update is essential for epidemiological purpose and also for rational and accurate use of antibiotics by clinicians. The present

study aimed to determine the etiology and antibiotic resistance pattern in blood stream infections.

METHODS

Study design

A retrospective study was conducted from the records of automated blood culture (bact alert) and drug susceptibility testing (vitek) results in the clinical microbiology laboratory from June, 2016 to July, 2018 at Ananta institute of medical sciences and research centre, Rajsamand. This data includes 377 records of hospitalised patients who were admitted to different units of hospital during the study period.

Sampling technique and data collection

Blood cultures were performed for different age groups up to 90 years. Samples were collected by phlebotomist from the patients after disinfection of vein puncture site with 70% alcohol. 3-4ml of blood was inoculated in 30ml BacT/Alert blood culture bottles for paediatrics and 4-5ml blood was inoculated in 30ml BacT/Alert blood culture bottles for adults. These bottles were incubated in BacT/Alert automated system. The bottles which showed positive signal for growth were removed from the automated system and subculture was done on Nutrient agar, blood agar and MacConkey's agar. Smears from the colony of different agar plates were prepared and stained with Gram stain to identify the growth (i.e. gram positive or gram negative bacteria). Then the growth of the bacteria was run on VITEK II automated system for identification of the organism and Antibiotic Sensitivity. If there is no growth of bacteria within five days of inoculation of blood sample into BacT/Alert blood culture bottle then the sample is considered to be negative.

Data regarding the age, sex, isolate and its antimicrobial pattern was collected and statistical analysis of the data was done by Chi square test to study the P value using social science statistics online software.

RESULTS

A total of 377 samples were screened for blood culture from hospitalized patients of different units. 20.68% of samples were positive for blood stream infections caused by different pathogens (Table 1).

A total of 78 microorganisms were isolated from 377 samples. Among which gram negative bacilli was observed in 52.56%, gram positive cocci in 44.87% and yeast in 2.56% samples. The leading isolate among the gram positive cocci were CONS (coagulase negative *staphylococci*) and among the gram negative bacilli, *Klebsiella pneumoniae*. Details of each isolate were mentioned in Table 1. Only two samples were found to be positive for yeast i.e. *Candida tropicalis*.

Table 1: Bacteria and yeast isolated from blood culture samples.

	Isolate	Positive %
Gram negative bacilli (A)	*Acinetobacter baumannii*	4 (9.75%)
	Acinetobacter iwoffii	1 (2.44%)
	Burkholderia cepaciae	1 (2.44%)
	Escherichia coli	10 (24.39%)
	Enterobacter cloacae Complex	2 (4.87%)
	Klebsiella pneumoniae	17 (41.46%)
	Pseudomonas aeruginosa	3 (7.31%)
	Spingomonas paucimobilis	1 (2.44%)
	Stenotrophomonas maltophilia	1 (2.44%)
	Serratia marcescenes	1 (2.44%)
Total		41 (100%)
Gram positive cocci (B)	*Staphylococcus aureus*	3 (8.57%)
	Staphylococcus cohnii#	2 (5.71%)
	Staphylococcus epidermidis#	6 (17.14%)
	Staphylococcus haemolyticus#	4 (11.48%)
	Staphylococcus hominis#	3 (8.57%)
	Staphylococcus lentus#	2 (5.71%)
	Staphylococcus pseudintermedius#	2 (5.71%)
	Enterococcus faecalis	3 (8.57%)
	CONS	10 (28.57%)
Total		35 (100%)
Yeast (C)	*Candida tropicalis*	2(100%)
Total (A+B+C)		78/377* (20.68%)

*Total number of samples tested, CONS-coagulase negative *staphylococcus*, # CONS

Isolates were predominant in males (62.82%) as compared to females (37.18%) (Table 2). Paediatric patients were more (31.57%) exposed to BSI than adult and elderly patients (23.52%). Statistical analysis showed a P value of 0.03. CONS were the leading pathogens in paediatric patients. *Klebsiella pneumoniae* was the leading pathogen among the adult and elderly patients. 83.3% (65) of samples were culture positive in <24hours, 15.4% (12) in between 24 <48hours, 1.3% (1) between 48-72hours.

Table 2: Sex wise and age wise distribution of positive and negative blood culture samples.

Variable	Blood culture result			P value
	Positive	Negative	Total	
Male	49	191	240	X^2=0.03 P=0.86
Female	29	108	137	
Age				
<5 years	25	58	83	X^2=6.88 P=0.03
5 <15 year	5	37	42	
>15 years	48	204	252	

Among the gram-negative isolates, *Escherichia coli* showed 100% sensitivity to colistin and tigecycline, 80% to ertapenem. *Acinetobacter* species showed 80% sensitivity to colistin and 70% to amikacin. *Enterobacter cloacae* showed 100% sensitivity to tigecycline,

Klebsiella pneumoniae showed 100% sensitivity to colistin and 88.3% to tigecycline. *Pseudomonas aeruginosa* showed 66.7% sensitivity to colistin (Table 3). Among gram positive isolates, CONS showed 93.1% sensitivity to linezolid, 89.7% to tigecycline and 86.2% to vancomycin. *Staphylococcus aureus* showed 100% sensitivity to oxacillin, gentamicin, linezolid, vancomycin, tetracycline and tigecycline. E*nterococcus faecalis* showed 100% sensitivity to gentamicin, linezolid and vancomycin (Table 4).

Very low positivity 1 (2.44%) was observed for *Spingomonas paucimobilis, Stenotrophomonas maltophilia, Burkholderia cepaciae* and *Serratia marcescenes.*

Trimethoprim	51.7	66.6	50

DISCUSSION

The overall frequency of blood culture isolates in present study was (20.68%). This is comparable with studies conducted in India by Pal et al, 2016 (22.3%) and Gill et al, 2016 (24.8%).[5,4] However, some studies have reported high frequency of bacterial pathogens from blood cultures (24.2%-37.1%).[6,7] This may be due to use of different blood culture systems, different sample size, variations in study design and protocols, different geographical locations, variations in causative agents and the policies adopted for infection control between countries. Incidence of gram negative bacilli (GNB) was 52.56% and gram positive cocci (GPC) were 44.87%. Similar findings with high frequency of GNB as compared to GPC were previously reported by an Indian study.[8]

In our study, coagulase negative *staphylococcus* was the leading blood culture isolates (37.1%). Similar results were reported from India (61%) and globally (42%).[9,10] They often occur as skin contaminants during the collection of blood. Cross infections in ICU'S with multidrug resistant CONS can be prevented by use of appropriate antimicrobial agents. There is a need for differentiation between true pathogen and contaminant which can be achieved by correlating clinically the blood culture isolate and time taken for positivity of CONS.[11] Among the GPC group CONS showed high frequency of antimicrobial resistance as compared to others (Table 4). *Staphylococcus* aureus was 100% sensitivite to oxacillin, gentamicin, linezolid, vancomycin, tetracycline and tigecycline. Similarly, an earlier study reported 100% sensitivity to linezolid and vancomycin.[8]

Enterococcus faecalis was observed in (8.5%) of gram positive cocci. Similar findings (8.4%) were reported by an earlier Indian study.[11] It is a normal flora of female genitourinary tract and gastrointestinal tract. Though vancomycin resistance was reported since a decade, in the present study no resistance to vancomycin was observed for *Enterococcus faecalis*. This may be due to differences in the circulating strains. However, an earlier study from north India reported 23% of vancomycin rersistant enterococci.[11]

Gram negative bacteria accounted for more than fifty percent among the total isolates of the blood culture. This is consistent with an earlier study, though there is difference in the range of isolates.[1] Among the non fermenters, *Acinetobacter* species and *psuedomonas aeruginosa* showed high level resistance to cephalosporins and carbapenems. There is increase in the trend of carbapenem resistance to *Acinetobacter* species.[11] This may be because of extensive use of these antimicrobials. The overall antimicrobial resistance of gram negative bacteria and gram positive bacteria varied from 0% to 100% in our study. This is different when compared to a previous study which reported a higher resistance in gram negative bacteria (20-100%) as compared to gram positive bacteria (23.5%-58.8%).[12] Among the *Klebsiella pneumoniae* isolates high level sensitivity was shown by colistin 100% followed by tigecycline 88.3%, imipenem 64.7% and meropenem 41.2%. Singh et al, 2014 reported 100% and 71.4% sensitivity for imipenem and meropenem respectively each.[8] *Eschericia coli* showed high level sensitivity to colistin and tigecycline 100%, followed by ertapenem 80%, amikacin and gentamicin 70%. The sensitivity of gentamicin in our study was much higher as compared to an earlier Indian study 35%.[13]

Differences in antimicrobial resistant pattern in different studies may be due to circulation of different strains in different regions at different times.

Among the yeast isolates *Candida tropicalis* was isolated in two blood culture samples. Both the isolates were 100% sensitive to fluconozole, voriconazole, caspofungi, micafungin, amphotericin-B, and flucytosin. However, studies from different parts of India reported the emergence of *nonalbicans Candida* and resistant to widely used antifungal agents.[14,15]

CONCLUSION

Coagulase negative *staphylococcus* and *Klebsiella pneumoniae* were the predominant isolates of the study. High level multidrug resistance was observed in both GPC and GNB. Tigecycline and colistin remains the choice of antibiotics for gram-negative bacilli. Gentamicin, linezolid, vancomycin and tigecycline are the choice of antibiotics for gram positive cocci. Good antibiotic policy and strict hospital infection control measures may help to curb the emergence of multidrug resistant pathogens. There is a need for continuous monitoring and updating the BSI isolates and their antimicrobial patterns for an early effective approach to treatment.

A B S T R A C T

Critical care populations are at high risk for Multi drug resistant organisms (MDRO) colonization because of rampant use of broad-spectrum antibiotics leading to colonization with resistant strains, Screening for MDR organisms is one of the many approaches needed to deal with the very major clinical problem concerning drug resistance. This study was planned to look for antibiotic resistance by simple phenotypic methods to detect Resistant *Enterobacteriaceae* include broad spectrum β-lactamase producing *Enterobacteriaceae* (ESBL and AmpC β-lactamases) and carbapenem-resistant *Enterobacteriaceae* (CRE)and or combinations of any in one go and nasal screening for Methicillin Resistant Staphylococcus Aureus (MRSA). Total of 110 patients admitted intensive care unit were screened by taking rectal and nasal swab over period of year. In our study 234-gram negative bacilli were isolated from 110 rectal swabs among those were 54(23.7%) ESBL, 22(9.4%) Amp C, and 30 (12.8%) isolates were carbapenem resistant which includes 21(8.9%) isolates were cabapenemase producer by MHT and MBL screen and 9(2.64%) isolates were carbapenemase +Amp C+ESBL combined producers. Nasal MRSA carriage rate was 8%. Present study emphasis the need for strong infection control programs to detect colonization of gut and other anatomical site by multidrug resistant organisms. Need to reduce overuse of antibiotics and establish good antibiotic stewardship programs and implementation of screening in intensive care unit.

Introduction

Human body commensal flora is a diverse ecosystem which is inhabited by aplethora of bacteria (Qin *et al.*, 2010). The healthy microbiota provides protective functions including ability to prevent colonization and or expansion of pathogens. Changes in the composition of the gut flora, may reduce colonization resistance and select for antibiotic resistance and which can happen silently, leading to the selection of highly resistant bacteria. An increase in gut permeability allows Bacterial translocation that is the invasion of indigenous intestinal bacteria through the gut mucosa to normally sterile tissues and the internal organs. (Vaishnavi, 2013) Endotoxins and other toxins can also cross the gut barrier. Bacteremia and endo-toxinaemia are among the mechanisms involved in severe sepsis and multiple organ failure (Arrieta *et al.*, 2006).

MDROs are defined as microorganisms, predominantly bacteria, that are resistant to one or more classes of antimicrobial agents. Critical care populations considered at high risk for Multi drug resistant organisms (MDRO) colonization based on factors such as antibiotic exposure history, presence of underlying diseases, prolonged duration of stay, exposure to other MDRO colonized patients, patients transferred from other facilities known to have a high prevalence of MDRO carriage, or having a history of recent hospital or nursing home stays so thereby induce healthcare-associated infections, undergo cross-transmission to other individuals, and cause limited outbreaks (MDROGuidelines2012 & MRGN guidelines 2016)

Staphylococcus aureus is a member of commensal micro flora and readily colonizes the anterior nares. Nasal carriage of S.aureus act as endogenous reservoir for clinical infections in colonized individuals or as a source of cross colonization for community spread (Kashmir *et al.*, 2014)

Screening for Multi-resistant Gram-negative bacilli (MRGN) organisms by a sensitive, specific and cost effective screening test may help the clinicians in the choice of appropriate antimicrobial therapy, provide baseline data about the epidemiology of MDR pathogen, to guide policy recommendations and help in infection control by early identification of patients, thereby facilitating an informed decision about infection control interventions These interventions may include notification to the concerned clinical and nursing team, infection control precautions such as isolation or cohort nursing of such patients, use of decolonization regimens, use of antibacterial prophylaxis during surgery or other invasive interventions of use of an appropriate agent for empirical antibiotic therapy in case of unconfirmed infection in a colonized patient (Bhattacharya 2011 & Deepa *et al.*, 2014). This study was planned to look for antibiotic resistance by simple phenotypic methods to detect Resistant.Multi-resistant Gram-negative bacilli include broad spectrum β-lactamase producing *Enterobacteriaceae* (ESBL and AmpC β-lactamases) and carbapenem-resistant Enterobacteriaceae (CRE)and or combinations of any in one go and nasal screening for Methicillin Resistant Staphylococcus Aureus(MRSA).

Materials and Methods

The present observational study was carried out in the Department of Microbiologyin tertiary care hospital.

Inclusion criteria

Patients admitted to intensive care unit with factors such as antibiotic exposure history, presence of underlying diseases, prolonged duration of stay, exposure to other MDRO colonized patients, or having a history of recent hospital or nursing home stays.

Exclusion criteria

Patients should not be a health worker, should not have any history of immuno-compromised status and patients who are not receiving antimicrobials.

Sample collection

2 Nasal swabs and 1 Rectal swab were collected from each patient admitted to intensive care unit.

Nasal swabs were taken by swirled while applying even pressure inside anterior nares with a sterile cotton swab (16). Rectal samples were collected in the sterile swab by inserting the swab 1cm into the rectum while rotating the swab. Rectal swabs are an appropriate

alternative to stool specimens (Lerner *et al.,* 2013). Total transit time to the laboratory was within 30 minutes. Samples were processed as per the standard protocols (Deepa *et al.,* 2014 & Lerner *et al.,* 2013)

All isolates of staphylococcus aureus from nasal swabs were processed routinely and tested with 30 mg cefoxitin discs (Hi-Media) on Mueller–Hinton agar plates by disk diffusion methodfor MRSA detection ((M100 27th edition 2017),16,17).

Resistant *Enterobacteriaceae* isolates to one or more classes of antimicrobial agents, resistant to third generation cephalosporins, resistant toeither of the carbapenems namely Imipenem, Ertapenem or Meropenem were selected for study. All the selected gram negative Enterobacteriaceae were tested by disc placement method (Deepa *et al.,* 2014, Neena *et al.,* 2012 & Shamsadh Begum *et al.,* 2015).

The lawn culture of test organismwas made on Muller–Hinton agar (MHA) as done for discdiffusion antimicrobial susceptibility test. In the center ofthe plate, imipenem (10 µg) (Inducer) disc was applied. At Antimicrobial susceptibility: the distance of 20 mm, the disc of cefotaxime (30 µg) was placed. From this disc, in a circular manner, clockwise, the discs of cefoxitin (30 µg) (Inducer), ceftriaxone (30 µg), ceftazidime (30 µg), ceftazidime + clavulinic acid (30/10µg), and aztreonam (30 µg) were placed such that any two adjacent discs were 20 mm apart from center to center (Figure 1). On overnight aerobic incubation at 37°C, the diameters of zones of inhibition were measured and interpreted as follows:

Extended-spectrum b-lactamase (Figure 2)

Zone diameter for aztreonam ≤27 mm, cefotaxime≤27 mm, ceftazidime ≤22 mm, and ceftriaxone ≤25 mm.

Susceptible to cefoxitin.

Increase in zone size with addition of inhibitor (ceftazidime+ clavulanic acid) by 5 mm or more.

AmpC b-lactamase (Figure 3)

Inducible

The blunting of zone of inhibition of Ceftazidime discs toward inducers

No increase of zone size with addition of inhibitor

Depressed mutants (DM)

Resistant to cefoxitin (≤ 14 mm) and cefotaxime

No increase of zone size with addition of inhibitor

Metalloβ-lactamases

Strains showing resistance to imipenem.

Multiple mechanisms

Resistant to cefoxitin

Blunting of zone toward inducer

Increase of zone size with addition of inhibitor by 5 mmor more.

The isolates showing resistance either of Carbapenemswere further analyzed as Carbapenem resistance in Gram-negative rods is mainly due to two mechanisms: first the production of carbapenem-hydrolyzing enzymes (i.e. serine carbapenemases and metallo-β-lactamases, and second the combination of membrane impermeability with production of ESBLs, pAmpC or ampC

overexpression (MDROGuidelines 2012). Double disc potentiation test (Figure 6) and Modified Hodge test (Figure 5) (Neena *et al.,* 2012; Shamsadh Begum *et al.,* 2015) was done on those carbapenem resistant isolates.

Modified Hodge test (Lee *et al.,* 2001 and Yong, *et al.,* 2002)

An overnight culture suspension of E. coli ATCC 25922 adjusted to 0.5 McFarland standard was inoculated using a sterile cotton swab on the surface of a MHA. After drying 10 µg imipenem disc was placed at the center of the plate and the test strain was streaked heavily from the edge of the disc to the periphery of the plate. The plate was incubated overnight at 37°C. Indentation produced in the zone of inhibition produced by the imipenem indicates a positive test. Maximum four strains can be tested at a time (all four directions) which gives a presence of a "cloverleaf shaped" zone of inhibition if all four test strains are positive for MBL production

Double disc potentiation test (Lee *et al.,* 2001 & Yong, *et al.,* 2002)

A 0.5 M EDTA solution was prepared by dissolving 186.1 g of disodium EDTA. (REACHEM, Chennai, India) in1000 ml of distilled water. The pH was adjusted to 8.0 by using NaOH (HI-MEDIA) and was sterilized by autoclaving.

An overnight liquid culture of the test isolate was adjusted to a turbidity of 0.5 McFarland standard and spread on the surface of a MHA plate. Two 10 µg imipenem discs were placed on the agar 15 mm apart (center to center). 10 µl of0.5 M EDTA is added to one of the imipenem disc to get a desired concentration of 750 µg. After incubating overnight at 37°C, the presence of an expanded growth inhibition zone between the two discs or increase of zone size of more than 7 mm in the disc potentiated with the EDTA (chelating agents) was interpreted as positive for MBL production

All the tests and their interpretations were according to the CLSIGuidelines (M100 27th edition 2017) and well-accepted methods by various authorities. (Lerner A *et al.,* 2013, Rodrigues C *et al.,* 2004, Neena V *et al.,* 2012 & Shamsadh Begum *et al.,* 2015)] the identity of the isolates and resistance pattern was further confirmed by using Vitek 2 GN ID (BioMerieux, France) with appropriate quality control.

Results and Discussion

Total of 110 patients admitted intensive care unit were screened over period of year.110 nasal swabs yielded 117 isolates most common being methicillin sensitive coagulase negative staphylococcus(MSCONS)42.7%, methicillin resistant coagulase negative staphylococcus (MRCONS) 34.18%, methicillin resistant coagulase positive staphylococcus(MRSA)8%, methicillin sensitive coagulase positive staphylococcus (MSSA) 10.25%. Nasal swab also yielded Serratia, Pseudomonas aeruginosa, Escherichia coli in five critically ill patients (Table 1).

110 rectal swabs yielded 234 isolates Resistant isolates toone or more classes of antimicrobial agents to third generation cephalosporins, either of the Carbapenems namely Imipenem, Ertapenem or Meropenem or Cefoxitin by disk diffusion method were selected for the study. Of the 234 isolates from rectal swab 112 isolates were multi drug resistant (Table 2). Among 125 (53.41%) isolates of Escherichia coli showed 68% were multi drug resistant.50 (1.47%) *Klebsiella spp.* showed 86% multi drug resistant. Only 7 of Enterobacter species were isolated but resistance rate was high as71%. There were few isolates of Citrobacter species, Proteus species.

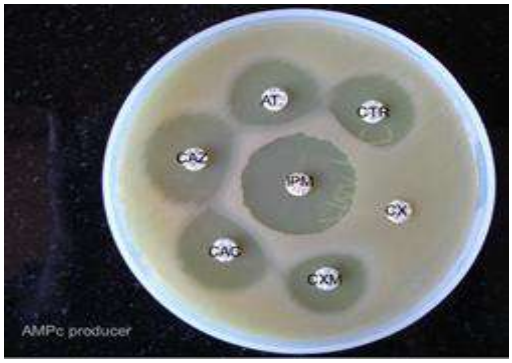

Fig.4 ESBL and AMPc producer

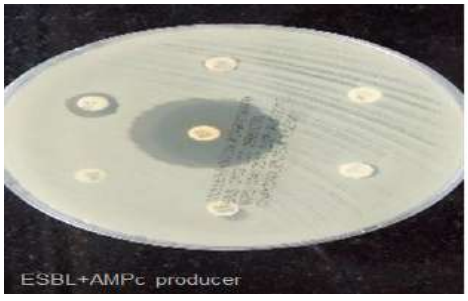

Fig.5 ESBL+ AMPc + carbapenemase producer

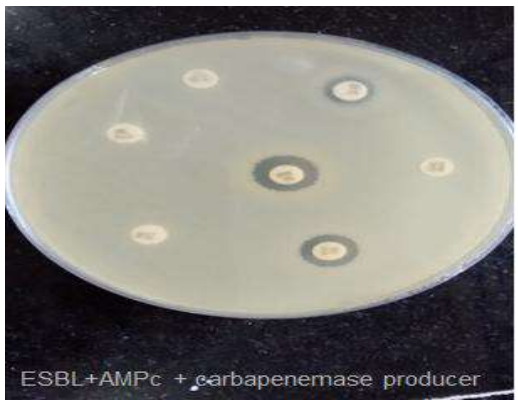

Fig.6 Modified HODGE test

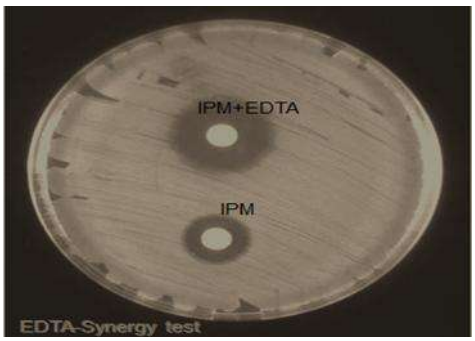
Fig.7 Double disc potentiation test



Enterococcus species and Candida species *as a* rectal colonizer. 54(28.7%) isolates ESBL producing *Enterobacteriaceae,* 31(13.1%) isolates were cabapenemase producer 9(2.64%) isolates were cabapenemase +Amp C+ESBL combined producers (Table 3). Beta-lactamases also known as penicillinase are enzymes produced bacteria that provide multi resistance to β-lactam antibiotics such as penicilins cephalosporins, cephamycins, and carbapenems**.** Bacterial translocation of such multi resistant organism may be a normal phenomenon occurring on frequent basis in healthy individuals without any deleterious consequences. But when the immune system is challenged extensively, it

breaks down and results in septic complications at different sites away from the main focus. Cross transmission of the resistant strains can occur relatively easily if strong hygiene measures are not taken.

In our study 234-gram negative bacilli were isolated from 110 rectal swabs among them 146 were multi drug resistant gram-negative bacilli, among those 112(47.8%) were-β lactamases producers 54(23.7%) ESBL, 22(9.4%) Amp C, and 31(13.1%) isolates were cabapenemase producer by MHT and MBL screen and 9(2.64%) isolates were cabapenemase + Amp C + ESBL combined producers. Shamshad begum Esak *et al.,* 2015; Deshmukh *et al.,* 2011; Shanmugan *et al.,* 2013 Priya Data *et al.,* 2012; Gupta *et al.,* 2006have reported varying resistance rates of carbapenem in Enterobacteriaceae ranging from 5,75% to 51 %. Similar study by Deepa *et al.,* 2014 showed 42.8% isolates were cabapenemase producer from gut asymptomatic colonization.

In present study nasal MRSA carriage rate was8%as compared to study by Eddie Chi Man Leung *et al.,* (2013) it was 1.38%, 14% in study by A Kohlenberg *et al.,* (2011). Screening for asymptomatic MDRO colonization will reduced the prevalence of MDRO among hospitalized patients by using a variety of combined interventions like improvements in hand hygiene, use of Contact Precautions until patients are culture-negative for a target MDRO, active surveillance cultures (ASC), education, enhanced environmental cleaning, and improvements in communication about patients with MDROs within and between healthcare facilities. However, screening patients who were not receiving antimicrobials had a minimal beneficial impact. There are few limitations in the study that we screened only nasal and gut Enterobacteriaceae colonization, need to include other anatomical sites from other wards like long term care facilities and conduct larger epidemiological study.

Present study emphasis the need for strong infection control programs to detect colonization of gut and other anatomical site by multidrug resistant organisms. Need to reduce overuse of Antibiotics and establish good antibiotic stewardship programs. Implementation of screening in intensive care unit could reduce the MDRO transmission.

A B S T R A C T

Bloodstream infections (BSIs) are among the most serious infections acquired by hospitalized patients requiring intensive care. The existence of a pathogen population with an ever-increasing resistance to antibiotics has complicated the clinical problems. This retrospective study was undertaken with a view to compile and analyse the common isolates of BSIs along with resistance pattern in a tertiary care teaching hospital. Retrospective study was conducted to identify the microbial profile in the blood culture isolates and their antibiotic susceptibility patterns in a tertiary care teaching hospital. The reports of specimens submitted for blood culture during the period of 2012-2015 to the microbiology laboratory were obtained, the positive cultures were identified, and data on the microbial species and their antibiotic patterns were collected and statically analysed. There were 4964 blood culture samples, of which 543were identified to be culture positive. Of the total culture positives177 (32.59%) were Gram positive bacteria; 309 (56.91%) were gram negative bacteria and 57 (10.50%) were *Candida species*. Among the gram positive bacteria150 (27.62%) were Coagulase negative Staphylococci (CoNS); 16 (2.94%) were *Staphylococococcus aureus* and 11 (2.02%) were Enterococcus species. In the Gram negative bacteria *E.coli* was 140 (25.78%); *Klebsiella pneumonia* was 92 (16.94%); *Acinetobacter* species was 25 (4.60%); *Pseudomonas species*was32 (5.89%). Statically significant resistance was observed in CoNS for Oxacillin; in *E.coli* for Ciproflaxacin, Amoxicillin-clavulanic acid, Piperacillin + tazobactam, Cefuroxime; and in *Klebsiella pneumoniae* for Amoxicillin-clavulanic acid, Piperacillin+tazobactam, Imipenem. CoNS is the common gram positive isolates followed by *E.coli* and *Klebsiella pneumoniae* in gram negative organisms of BSI in our setup. Significant resistance was observed for third generation cephalosporins, fluoroquinoles and piperacillin +tazobactam combination. Ongoing surveillance for antimicrobial susceptibility remains essential in case of BSI and will enhance efforts to identify resistance and attempt to prevent its spread.

Introduction

One of the major global problems is the rising trend in antibiotic-resistance mainly in hospitals, and also in the community which is a difficult condition to control without considerable measures and resources. The consequences of increased drug resistance are by far-reaching beyond any doubt when

it is concerned with Blood stream Infection (BSI) making antibiotic resistance an important health issue. In many countries antimicrobial resistance among bloodstream pathogens have severe consequences including increased health care cost, morbidity and mortality. This is especially true in countries like India, where, antibiotics are used extensively and considerable resistance is reported from all over the country.

BSI is potentially life-threatening condition and requires rapid identification with the antibiotic susceptibility pattern of the causative agent in order to facilitate specific antimicrobial therapy. Despite the availability of newer antibiotics, emerging antimicrobial resistance has become an increasing problem in many pathogens throughout the world. The organisms responsible for bacteraemia vary across geographical boundaries; but few of the pathogens like *E. coli, Klebsiella spp., Staphylococcus aureus, Coagulase negative Staphylococci (CoNS), Pseudomonas spp., Salmonella spp. and Acinetobacter spp.* are constantly associated with bacteraemia because of their frequent isolation and multi-drug resistance which has reached worrying levels. Also some phenotypes such as MRSA, VRE, MR-CoNS, and Carabapenamase producing gram negative organisms such as *P.aeruginosa* & *Acinetobacter baumanii* are of particular concern. Even central venous catheter, invasive devices, surgery and long term stay in ICUs puts the patients at higher risk of BSI.

For practicing physicians, clinical microbiologists and public health officials, knowledge of local antimicrobial resistance patterns is essential to guide empirical and pathogen specific therapy. This information is also critical for optimal decisions regarding formulation of hospital infection control policies, rational public healthcare policies, and national and international research agendas in that area. Antimicrobial resistance surveillance is essential to track changes in microbial populations, estimate the magnitude of the problem and to design and evaluate interventions. However, there is no national level information on resistance among bacteria causing bloodstream infections in India.

Therefore, the present study was a modest attempt with an objective to evaluate the bacteriological profile and tracing resistance among patients with BSI at our hospital. This study also summarizes the strategic resistance patterns of the isolated organisms from the patients admitted in our tertiary care hospital.

Materials and Methods

This retrospective analysis on blood culture-positive isolates and their antimicrobial susceptibility pattern was carried out during the period starting from 2012-2015 in a tertiary care teaching hospital in southern Rajasthan. Approval for the study was obtained from hospital ethics committee and consent was waived since this is a retrospective evaluation. Only one blood isolate per patient was included in the study. The blood sample were collected in BacT/ALERT FA (adult) and BacT/ALERT PFplus (paediatric) bottles; and received in the department. Inoculated bottles were incubated in BacT/ALERT 3D (Biomerieux) and growth indicated bottles were processed as per company instructions. Identification of microorganisms to species level and antimicrobial susceptibility testing was performed with the automated system vitek 2 compact (Biomerieux).

Statistical analysis was conducted using Microsoft excel 2010. Chi-square test was applied for the comparison of categorical

variables. *p* values less than 0.05 were considered as statically significant.

Results and Discussion

A total of 543 isolates from 4964 blood specimens cultured were analysed during study duration of 2.5 years (2012-2015). The overall culture positivity rate thus obtained was 10.93%. Out of the total isolates analysed, 84.71% were from intensive care units and rest 15.28% were from different wards (Table no.I).

The relative distribution frequency of blood isolates is depicted in table no. II. The aerobic or facultative bacterial isolates was found to be 89.50% and candida species were 10.50%. Among the pathogens; the most common isolates were 27.62% Coagulase negative staphylococci (CoNS), 25.78% *Escherichia coli*, 16.94% *Klebsiella pneumoniae*, 5.89% *Pseudomonas aeruginosa* and 5.70% *Non-albicans Candida species.*

The resistance pattern to antibiotics for gram negative isolates and gram positive isolates is shown in table no. III and IV respectively.

According to global surveillance reports, bloodstream isolates are the best candidates for the study of antimicrobial susceptibility of human bacterial pathogens. Patients with bacteraemia have remained a treatment challenge. The present study illustrates the BSI bacterial spectrum and antimicrobial resistance pattern in a tertiary care teaching hospital of southern Rajasthan.

During the study period a total 4964 blood samples for aerobic bacterial culture were received in the department for processing, of which 543 were culture positive; with an over all culture positivity rate of 10.93%.Similar rate of blood culture positivity of 12.7% was also reported by Chand wattal *et al.*,., from north India. Several studies across India have reported a varied range of positivity ranging from 3.72% to 44%.The varying rates of blood culture depends upon numerous factors such as the number and amount of blood cultures taken, the system and type of blood culture medium used for bacterial detection. In addition to this most of the patients already received some kind of antibiotics before they come to the tertiary care hospital and self-medication is very common because of the counter availability of medicines (Asmita Ashok, 2016).

In the present study, Gram negative bacteria was found to be responsible for56.90% and Gram positive bacteria caused 32.59% of the BSI. This observation is similar to the various studies done in the patients of developing countries (Vanitha 21-24). In the study conducted by Vanitha *et al.*, had reported 59.1% of gram negative organisms and 37.7% gram positive organisms. Similarly Mehta *et al.*,., also have reported gram negative organisms as the primary cause of BSI but with a higher rate of 80.96%; whereas only 18% were gram positives organisms in their study.

In the present study, CoNS were the most commonly isolated Gram positive cocci with an isolation rate of 27.62%, followed by the isolates of *S. aureus* and *Enterococci* contributing only 2.94% and 2.02% of respective isolation rates. In contrast, Asmita Patil *et al.*, and Rakhee baby *et al.*, have reported a higher isolation rate of 27.66% and 21.46% for S. aureus. Similar to our CoNS isolation rates; Chand Wattal also have reported 20.3%in blood. Anu Gupta *et al.*, and Mukherjee *et al.*, also had reported CoNS as most common Gram positive isolate; but with different isolation rates of 9.1% and 61% individually. Similar studies

from other countries carried out by Karlowsky *et al.,* and Japoni *et al.,* had reported 42% and 67.7% CoNS respectively. Previously, CoNS isolated from blood culture were considered as contaminants. But in recent years because of the increased use of intra-vascular devices, increase in immunocompromised patients and propensity to form biofilm by the organism; they are now considered as important agent for nosocomial bacteraemia. Meticulous skin disinfection at the time of venepuncture, determination of time to positivity, clinical correlation and appropriate antimicrobial therapy to prevent cross transmission from patient-to- patient can help to differentiate CoNS as potential contaminants or as true pathogens (Cockerill *et al.,* 1997, Kumar Y *et al.,* 2001). Also interpretation of blood cultures that are positive for CoNS require careful reasoning (Anu Gupta, 2010).

Among the Gram negative isolates, *E.coli,* (25.78%) was the primary isolate followed by *Klebsiella pneumoniae (16.94%),P. aeruginosa (5.89%),* and *Acinetobacter ssp. (4.60%)*. Similarly *E.coli* were reported to be most common gram negative bacilli from BSI in many studies. (Vinitha). Kalpesh Gohel *et al.,*; Wagner *et al.,* also reported E coli as commonest gram negative isolate in BSI. Although Kumar *et al.,* reported predominance of *Klebsiella* bacteraemia; in the current analysis it was the second most common gram negative organism. This diversity in the frequency can be justified due to the difference in the study plan, geographical location, seasonal variation, hospital infection control policies and disparity of the etiological agents (Asmita Ashok Patil, 2016).

In the present study, *Candida* spp. accounted for 10.50% of the BSI pathogens (5.70% Non-albicans candida and 4.78% *Candida albicans*). This data is comparable to the studies conducted by Anu Gupta *et al.,* (13%) and Chand Wattal *et al.,* (17.5%). According to surveillance data from the US centre for disease control and prevention, candida accounts for 12% of all hospital acquired BSIs (Hidron *et al.,* 2008). The fungal BSI are on rise due to extensive use of antibiotics, aggressive treatment of various diseases, increasing use of invasive devices, an increasing surviving AIDS patients etc. (Anu Gupta, 2010). These all factors in addition to solid organ malignancy, previous surgery, and increase in use of antifungal agents also contributed for the same (Chand Wattal, 2014).

The antimicrobial resistance pattern in the present study for Gram positive isolates was statically significant only for Oxacillin in CoNS isolates during the study period .Anu Gupta *et al.,* also had stated increased methicillin resistant during the two year study periods. This indicates that infections by CoNS may constitute a significant threat to septicemia in our locale and the spectrum of organisms is subject to geographical alterations. We report 100% sensitivity to vancomycin and linezolid in *Staphylococcus aureus*; whereas vancomycin resistance of 36.36% (4/11) in Enterococci was noted with 100% linezolid sensitivity. Anu Gupta *et al.,* also had reported 16.8% vancomycin resistance in Enterococci. The possible explanation for this may be due to lower number of isolates of S. aureus in comparison to CoNS; and may be the judicious use of vancomycin and linezolid in our setup.

Among the Enterobactericiae; *E. Coli* and *Klebsiella pneumonia* were the commonest to be isolated. Stastical comparison was done between the resistance pattern of isolated strains in the year 2012-2013 and 2014-2015. Statistically significant

resistance was observed for Ciprofloxacin, Amoxicillin-clavulanic acid, Piperacillin-tazobactam, and Cefuroxime in E.coli. Imipenem did not show any significant resistance in *E.coli* during study period. In *Klebsiella pneumoniae* Amoxicillin-clavulanic acid, Piperacillin- tazobactam, and Imipenem were significantly resistant. Anu Gupta *et al.,* also had reported alarming increase of resistance for most of the antibiotics during the study period. Also there was increase in the imipenem resistance in *E.coli*.

Among the Non-Enterobactericiae; no significant resistance was observed for any antibiotics during the study period. The possible explanation may be the fewer isolates of Pseudomonas species and *Acinetobacter* species.

Table.1 Distribution of positive blood cultures based on location of the patient (ICU & Wards)

Location	**2012**	**2013**	**2014**	**2015**	**Total**

One of the important outcomes of the present study was the relief for intensivist that resistant level of life saving drugs like Meropenem and Imipenem has not yet

increased to alarming stage. Thus these antimicrobials can be used as an early commencement treatment and later deescalate which can plays a vital role in reducing morbidity and mortality in BSI. The basis for this early treatment is the information about the likely pathogen and its antibiotic resistance pattern. Present study provides much needed information on the prevalence and antibiotic sensitivity pattern of prevalent blood pathogens. The analysis of resistance will help in formulating antibiotic policy and to decide the vacation period for any antibiotic in particular if required. The data will also help in limiting the indiscriminate use of antibiotics (Asmita *et al*., 2016). The main forces driving the increase in antimicrobial resistant bacteria are poor infection control practices and inappropriate use of antibiotics. Specific antibiotic utilization strategies like antibiotic restriction, combination therapy, and antibiotic recycling may help to decrease or prevent the emergence of resistance. Specific usage based on susceptibility testing may also reduce the incidence of BSIs (Vanitha).

In the current study, we also acknowledge several limitations to our study. First this is a single centre study and may not reflect the true status of the antimicrobial pattern. Second, the duration of the study is short and needed to be extended to get a prolific result. Though the fungaemia was seen due to Candida isolates (non-albicans), data from antifungal susceptilibility could be added benefit.

In conclusion, the present study revealed that Gram negative bacilli i.e. *E. coli* and *Klebsiella pneumoniae* predominantly an leading cause of BSI in our tertiary care setup; followed by CoNS. The significance of CoNS bacteraemia should be evaluated better in light of clinical profile of patient. In present study, increased resistance was observed in CoNS for oxacillin; an alarming increase of antibiotic resistance for various antibiotics was noted for *Klebsiella pneumoniae* during study period. E.coli showed significant resistant to Ciprofloxacin, Amoxicillin-clavulanic acid, Piperacillin- tazobactam, and Cefuroxime in *E.coli* with no increase in carbapenems resistance. This calls for implementation of strict antibiotic prescribing policies and hospital infection control guidelines. Ongoing surveillance for antimicrobial susceptibility remains essential in case of BSI and will enhance efforts to identify resistance and attempt to prevent its spread.

Chronic suppurative otitis media

ABSTRACT

Background: Otomycosis is one of the most common forms of otitis externa. It is often seen in cases of Chronic Suppurative Otitis Media. It is important to treat otomycosis effectively in cases of CSOM as both conditions worsen each other.
Objectives: To study the aetiology of otomycosis and fungal profile in patients of diagnosed CSOM at ENT Clinic, Udaipur.
Materials & Methods: A total of 100 clinically diagnosed patients of CSOM were enrolled in the study and the samples were obtained from each patient using sterile cotton swab and were studied for fungal profile.
Results: The most common fungi found in CSOM are Candida and Aspergillus species. In the present study out of 95 culture positive cases of CSOM, fungi were found in 13 cases (13.68%). Candida species was most common found in 10.52% of all cases and Aspergillus was observed in 3.15% of all cases. Out of all candida species 60% were albicans.

1. Introduction

Fungal infections are also closely associated with cases of CSOM as fungi thrive well in moist pus but many authors have focused their attention on the bacterial flora, and very little is known about the mycological aspects of these, the importance of which has been increasing in the recent years because of the excessive use of broad spectrum antibiotics, corticosteroids and cytotoxic chemotherapy and an increase in the number of immune deficiency conditions.[1] Most common fungi being Aspergillus spp. and Candida spp.[2]

Chronicity of ear discharge is important factor in the cause of fungal infection of otitis media. It causes humid condition in the ear and alters the pH to alkaline. Epithelial debris which eventually helps the growth of fungus. Topical use of steroid and antibiotics cause the fungal infection in the middle ear.[3,4]

The most common causal fungal organisms are Aspergillus niger, Candida albicans, Actinomyces, Trichophyton, Aspergillus fumigatus and Candida tropicalis. Common predisposing factors include prolonged treatment with topical antibiotics, hearing aid use, regular swimming in contaminated water, trauma to the ear canal and immunosuppression.[5]

The symptoms of otomycosis are non-specific and include itching, otalgia, otorrhoea, aural fullness, hearing loss and tinnitus. Furthermore, although the classic sign of otomycosis is the presence of waving conidiophores, this is not universally present. Yeasts, such as Candida species, do not form the closely woven mass of hyphae that are formed by moulds, such as Aspergillus.[6]

More common is the finding of generalized inflammatory changes of the external canal (oedema, hyperaemia, granulomatous myringitis and aural discharge of variable colour.[7]

2. Materials and Methods

For identification of fungal organism, laboratory examination of the discharge was carried out microscopically (in 10% KOH preparations) for the presence of pus cells, budding yeast cells, fungal hyphae (septate or aseptate), etc direct microscopy and culture of the material on SDA with Chloramphenicol.

To the solution of 10%KOH, 10% of glycerol is added to prevent drying. Mix the above ingredients properly and store solution at room temperature. The material was spread on a glass slide over a drop of 10% KOH solution and covered with a cover slip. Slide was examined under the microscope for the presence of fungi.[8]

The swab material was cultured over SDA cultue plate and incubated at 37^0C temperature and was observed daily for fungal growth upto 2 weeks. The growth was observed for the following–

1. Rate of growth
2. Morphology of colony
3. Texture
4. Surface pigmentation

Microscopic examination like LP mount and slide culture were done to identify the fungi.

Gram staining was done for identification of yeast and yeast like cells.

Chlamydospore formation, germ tube tests and Candida CHROM agar were done to identify Candida albicans.

3. Results

In our study, growth of microorganisms was seen in 95% of the processed samples and 5% didn't show any growth.

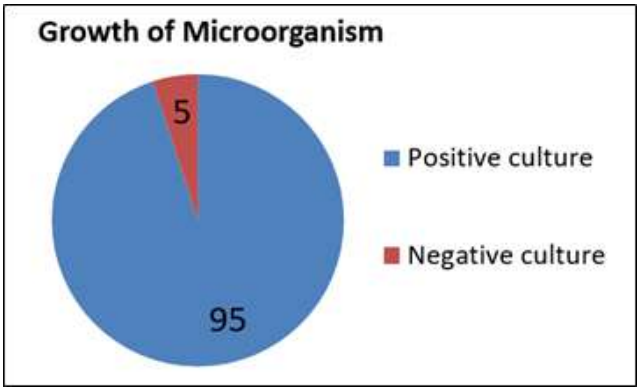

Fig. 1:

In our study Itching was the most common symptom (84.6%), followed by pain (53.8%), decreased hearing (30.7%) and sense of ear blockage (23%).

Total Fungal isolates were found in 13% of cases where Candida species was most common where it was isolated in 10% of cases. Out of total 13 fungal isolates Candida species was most common (76.92%) followed by Aspergillus species which was isolated in 23.07% of samples.

Table 1:

S. No.	Symptom	Percentage (%)
1	Itching	84.6
2	Pain	53.8
3	Decreased Hearing	30.7
4	Sense of blockage	23

Table 2:

Species	Tubotympanic	Atticoantral	Percentage
Aspergillus flavus	00	01	01 (0.99%)
Aspergillus niger	02	00	02 (1.85%)
Candida albicans	02	04	06 (5.55%)
Candida non albicans	01	03	04 (3.76%)

4. Discussion

Fungal infections of the middle ear are common as fungi thrive well in moist pus. In the present study ear discharge was seen in all the patients followed by itching (84.6%), pain (53.7%), decreased hearing (30.7%) and blocking sensation in the ear (23%). These finding were in agreement with study done my Rajpal Singh Punia et al in 2018.[9]

The most commonly found fungi in CSOM are Candida species and Aspergillus species.[10] In the present study, overall 13(13.68%) fungal isolates were obtained, out of which 4 (4.21%) were single fungal isolates. Candida species was most commonly isolated which was in 10% of cases. Out of total 10 (76.92%) candida isolates; 6 were albicans and 4 were non albicans followed by Aspergillus species which was isolated in 23.07% of samples where, Aspergillus niger was isolated in 15.38% and Aspergillus flavus 7.69% of cases. This was in accordance with study done by Harvinder Kumar et al and Prakash et al,[11] where total fungal isolates were 15% and 12.25% and Candida species was most common which was isolated in 60% of samples followed by Aspergillus species which was isolated in 40% cases whereas Prakash et al[11] reported Aspergillus species 70.83% and Candida species 29.17%. Aspergillus is a saprophytic mold and is one of the primary colonizers of the manmade substrata. Its rapid growth and production of a large number of small, dry, easily aerosolized conidia make it a significant contaminant with regards to air quality and potential human exposure-related illness. Aspergilli are common in airborne dust, and their growth is aided by cerumen and the slightly acidic pH of

the ear canal. The difference in the various studies could be due to the difference in the patient population studied and geographical variation.

5. Conclusion

The incidence of Otomycosis in patients of CSOM is high because of indiscriminate use of antibiotic and steroid drops. Discharge of CSOM also favours fungal growth.

ABSTRACT

Introduction: Contamination of operation theatres and Intensive care units through air, surface or article vehicle is major cause of surgical site and hospital acquired infections leading to increased morbidity and mortality.

Aims and Objective: The present study was conducted with aim to isolate and identify the nature of microbial contamination through air, surface and equipment of OT in a tertiary care teaching hospital.

Materials and Methods: Six months (August 2019 – January 2020) retrospective analysis of data by random sampling of the six OT's of the hospital was done. Air sampling was done by settle plate method. Surface samples were taken from different sites and equipments from the OT. Bacterial species were isolated and identified by conventional methods.

Results: Total 300 samples were collected and analysed Out of which 116 samples (38.66%) were positive for bacterial growth. The predominant bacterial species isolated from surface or equipment was Bacillus (48.27%), followed by Coagulase Negative Staphylococcus (21.55%), Gram Negative bacilli i.e. Klebsiella (8.62%) and least commonly isolated bacterial species was Staphylococcus aureus 2(1.72%). Air quality analysis showed highest bacterial CFU rate of 75cfu/m3 from general surgical operation theatres and Ophthalmology OT recorded least bacterial cfu rate of 20cfu/m3. Most common isolated species was Baciilus followed by Coagulase Negative Staphylococcii.

Conclusion: The study revealed that the OT's of our hospital showed a low bacterial contamination rate on surface swabbing and air quality CFU count per mm3 were within permissible limits. The present study emphasizes the need for periodic surveillance of OT's and ICU's and highlight the importance of early detection of bacterial contamination levels and prevention of hospital acquired infections.

1. Introduction

Hospital premises is in itself home to many kind of infections and have a potential role in transmission of so called Healthcare Associated Infections (HAI), also known as Noscomial or Hospital Aquired Infections. Hospital environmental hygiene plays very critical role in prevention of Hospital Aquired Infections and effective implementation of Hospital Infection Control programmes. HAIs are known to increases the morbidity, mortality and effective cost of treatment by increase in hospital stay.[1] Microbial contamination poses major risk factor in occurrence of surgical site infection (SSI).[2] Invasive procedures done without proper aseptic measures, irrational antibiotic usage and transmission of microbial infection between patients due to inadequate hospital infection control measures leads emergence and spread of microbial resistance in hot zones like OT's and ICU's.[3]

Microbiological surveillance is an important aspect of Infection control Programme, providing data regarding types and counts of microbial flora from various sites of healthcare facilities.[4] Knowledge of the incidence of

https://doi.org/10.18231/j.ijmmtd.2020.026

micro flora in a hospital is important for implementation of planning of adequate cleaning of hospital environment leading to prevention of further infections.

2. Aims & Objective

The present study was conducted to isolate and identify bacteriological profile and to evaluate the level of bacterial contamination found in surveillance of surface, equipment and air samples from various speciality OT's. It also aims at strengthening the Infection control strategy of the hospital towards prevention of HAI.

3. Materials and Methods

This retrospective study was conducted at the Department of Microbiology, Ananta Institute of Medical Sciences and Research Centre, Rajsamand Rajasthan over a period of six months from August 2019 - January 2020. The study is approved by Institutional Ethical Committee. The study includes random Air and Surface sampling from Operation Theatres. Samples were taken without prior information to nursing and cleaning staff so that true picture can be brought out.

Sampling procedures used in the study were surface swabbing and settle plate method.[5] All standard operating procedures were followed while taking samples. Sterile swabs soaked in nutrient broth were used for collecting samples from different sites and equipments (Instrument trolley, Anaesthesia trolley, table top, OT light, Monitor, Suction apparatus, Crash cart, IV infusion pump, door handle) from six OTs of the hospital.[6]

After labelling them properly, samples were transported to microbiology laboratory immediately for further processing. Blood agar and MacConkey agar culture plates were inoculated and incubated at 37 degree centigrade for 24 hours aerobically. Isolated bacterial species were identified by conventional method.[7] Air sampling was done by settle plate method. Blood agar plates were taken in OT and labelled with sample number, site, time and date. Plates were kept at about 1meter above the ground and 1meter from the wall at the center of OT and four corners.[8] Plates were exposed for an hour, at the time when OT's were functional. Exposed plates were sealed in plastic bags and sent to microbiology laboratory. Plates were incubated at 37degree centigrade for 24 hours. Colonies were counted and bacterial isolates were identified by conventional methods. Further, the colony forming unit (cfu) per plate was expressed as cfu/m^3 by Omeliansky formula.[9]

4. Results

Total 300 samples were processed, out of which bacterial species were isolated from 116 (38.66%) samples. Rest swab samples were sterile.

The Bacterial cfu/m^3 counts of air from all OTs ranged from 20cfu/m^3 (isolated from Opthalmology OT) to 75cfu/m^3 (isolated from General Surgery OT).

Table 1: Bacterial colony count on air sampling of various OT's.

Name of OT	Colony count(cfu/m^3)
General Surgery	75 cfu/m^3
Urology	65 cfu/m^3
Gynaecology & Obstetrics	55 cfu/m^3
ENT	25 cfu/m^3
Orthopaedics	23 cfu/m^3
Opthalmology	20 cfu/m^3

Table 2: Various Bacterial isolates from different OTs in Air sampling.

Name of OT	Microbes isolated
Orthopaedics	Bacillus ,CoNS
Urology	CoNS
Gynaecology & Obstetrics	Bacillus, CoNS
General Surgery	Bacillus, CoNS, Micrococci
ENT	Bacillus, CoNS
Opthalmology	Bacillus, CoNS

Bacillus species and Coagulase Negative Staphylococci (CoNS) were the most common isolates from different OTs in air sampling.

Table 3: Number of Bacterial isolates obtained from OTs in Surface Sampling.

Bacterial isolates	Number	% (n=116)
Bacillus	56	48.27%
CoNS	25	21.55%
Klebsiella	10	8.62%
Escherichia coli	08	6.89%
Micrococci	07	6.03%
Acinetobacter species	05	4.31%
Pseudomonas species	03	2.58%
Staphylococcus aureus	02	1.72%

Out of Total Positive Bacterial isolates most common was Bacillus (48.27%), followed by CoNS(21.55%) and least common Staphylococcus aureus (1.72%).

5. Discussion

Microbial contamination in OT leading to post operative infections can have serious implications for patients and their close contacts. A case of suspected HAIs is aggressively investigated by performing cultures from body sites of target patient, other close patients, health care staff working in wards and ICU's and environment.[10]

Specimens must be selected very carefully to obtain authentic and meaningful results. Hospital acquired infections prolongs patients hospital stay, increases morbidity, increase resistance to antimicrobials, represent a additional

financial burden for health system and cause unnecessary deaths.[5]

Prevention measures that need to be practiced to avoid such critical situations rest not only with the operating personnel but also with the entire infection control team. In this context, monitoring and microbiological surveillance can serve as warning system for change in the type and count of microbial flora.[11]

Hygienic condition of operation theatre is reflected by Microbiological quality of its air. Settle plates are believed to be more sensitive in detecting any deterioration in the microbial contamination of air in the operation theatre and conditions that could compromise the quality of the air in OT.[12]

In the present study, the count ranged between 20 – 75 cfu/m^3 of air which is well within permissible limits and correlate well with studies from Dipendra et al and Desai et al,[5,13] where as Anjali et al[11] have reported a high counts from air sampling. Variability in results in different studies can be attributed to various factors like method of surveillance, time of sampling (random /operational), ventilation of OT, disinfectants and method of sterilization used in infection control program. Highest colony forming unit count per cubic meter of air in our study was observed from General Surgery OT and least with Ophthalmology OT which coincides with study by Dipendra et al. High count seen in General Surgery OT's can be directly related to patient load in General Surgery OT and infective profile of patients in General surgery compared to Ophthalmic OT.[5]

In surface sampling, out of total 116 positive samples (38.66%), Bacillus species was most common isolate (48.27%) which is also considered to be environmental contaminant, followed by CoNS(21.55%) which is a common commensal organism and are also an important cause of SSI,[5] and shedding of CoNS from skin of Healthcare workers and patients and its easy cross transmission may be the reason for its presence in the study. This coincides with other studies by Pasquarella et al., and Desai et al.[12,13] In our study least common isolate was Staphylococcus aureus (1.72%) which is a potential pathogen and an important cause of skin and soft tissue infection. The instruments and article which were sterilised by autoclave showed no growth and highly touched surfaces like door handles, IV stand and OT lights also showed no growth of bacteria.

6. Conclusion

Our study shows that the microbiological quality of air and surfaces in OT of our hospital is satisfactory. This data can be used to set regional standards for level of acceptable microbial population and for suggesting guidelines to decrease the microbial population rates in indoor air.

The high prevalence of infective sources in hospital operation theatre environment is alarming and there is a need for strengthening of surveillance and proper implementation of infection control protocol which should be adopted at all levels of health care. Therefore, more extensive studies are required in the field for monitoring, surveillance methods and comparison of compliance between healthcare facilities, along with infection control measures which will be very useful in controlling HAIs.

ABSTRACT

Objective: The objective of our study was to examine the aerobic bacteriological profile and antibiotic sensitivity pattern to locally available antibiotics in chronic suppurative otitis media (CSOM) in Rajsamand district of Rajasthan state in India.
Materials and methods: This prospective study was conducted in the department of otorhinolaryngology, Ananta Institute of Medical Sciences, Rajsamand for a period of one year from February 2017 to February 2018. Aural swabs were taken on the first day of attendance of the patients to ENT OPD before any local medication was given to the patient, using sterile cotton wool swabs and sterile ear specula and sent for culture and sensitivity.
Results: A total of 150 cases of CSOM were selected for the study out of which 109 cases were of unilateral CSOM and 41 cases were having bilateral disease. Thus, a total of 191 swabs were taken for analysis. Out of 191 swabs processed, microbial growth was seen in 176 samples while 15 samples showed no growth. 121 (68.75%) samples showed mono-microbial growth while 55 (31.25%) samples showed poly-microbial growth. The peak incidence of CSOM was found in the age group 31-45 years (34.66%) followed by age group 16-30 years (27.33%). Females (62%) were more commonly affected than males (38%) and the female: male ratio was 1.6:1. *Pseudomonas aeruginosa (38.63%) was the most commonly isolated bacterial pathogen followed by staphylococcus aureus (35.22%) and klebsiella sp. (10.22%).*
Conclusion: A thorough and precise knowledge of the etiological agents causing CSOM and their antimicrobial susceptibility is of essential importance for an effective and efficient treatment and thus in further prevention of both complications and development of antibiotic resistance which is becoming more common now a days.

Keywords: Chronic suppurative otitis media, antibiotic resistance, staphylococcus aureus, Amikacin

INTRODUCTION

Chronic suppurative otitis media (CSOM) is a major problem globally since prehistoric times with higher incidence in developing countries because of poor socio-economic status and lack of health education. [1]

CSOM is a long standing infection of a part or whole of the middle ear cleft. Clinically, CSOM is divided into two major types: Tubotympanic CSOM i.e. 'Safe' or 'Benign' type of CSOM and Atticoantral i.e. 'unsafe' or 'dangerous' type of CSOM. [2]

CSOM is found to be the single major cause for conductive deafness (66.3%) and it is also responsible for 1.5% of speech disorders. [3]

The indiscriminate, haphazard and half hearted use of antibiotics and poor follow up of the patients have resulted in persistent changes in the bacteriological pattern of the disease, the advent of new antimicrobials, anti-inflammatory and anti-histamine agents make an evaluation of bacterial flora of CSOM important. [4]

The objective of our study was to examine the bacteriological profile and antibiotic sensitivity pattern to locally available antibiotics in CSOM.

MATERIALS AND METHODS

This prospective study was conducted in the department of otorhinolaryngology, Ananta Institute of Medical Sciences, Rajsamand for a period of one year from February 2017 to February 2018.

Aural swabs were taken on the first day of attendance of the patients to ENT OPD before any local medication was given to the patient, using sterile cotton wool swabs and sterile ear specula. The collected samples were enclosed in airtight plastic tubing and then transported to the microbiology test laboratory. The samples were always taken before cleaning/suctioning the ear canals of the excess purulent exudates. Samples from bilaterally discharging ears were collected separately. The material was inoculated on Sheep Blood agar, Mac Conkey's agar, Chocolate agar, Robertson's Cooked meat broth for aerobic and anaerobic bacteria. The swabs were incubated for 48 hr and 72hr. Organisms were identified using standard procedures. [5] Antimicrobial sensitivity testing for aerobic isolates was carried out by Kirby Bauer disc diffusion method on Muller Hinton agar. Results were interpreted in accordance with central laboratory standards institute guide-lines. [6]

RESULTS

A total of 150 cases of CSOM were selected for the study out of which 109 cases were of unilateral CSOM and 41 cases were having bilateral disease. Thus, a total of 191 swabs were taken for analysis.

Out of 191 swabs processed, microbial growth was seen in 176 samples while 15 samples showed no growth. 121 (68.75%) samples showed mono-microbial growth while 55 (31.25%) samples showed poly-microbial growth.

In present study, age of the patients ranges from 10 months to 73 years. The peak incidence of CSOM was found in the age group 31-45 years (34.66%) followed by age group 16-30 years (27.33%). Females (62%) were more commonly affected than males (38%) and the female: male ratio was 1.6:1. (table.1)

Microbiological profile of isolates from patients of CSOM and their antibiotic sensitivity pattern is depicted in table.2 and table.3 respectively.

Table.1 Age wise distribution of patients with CSOM

S.No.	Age-group (years)	Number	Unilateral	Bilateral	Mono-microbial	Poly-microbial	Sterile	Total
1.	0-15	23	11	12	22	9	4	35
2.	16-30	41	34	7	33	12	3	48

11.	Cefotaxime	27 (39.70%)	26 (41.93%)	1(5.55%)	8 (47.05%)	3(37.5%)	0
12.	Ceftazidime	51(75%)	44 (70.96%)	1(5.55%)	9 (52.94%)	0	0
13.	Piperacillin+ Tazobactam	51(75%)	55 (88.70%)	6 (33.33%)	6 (35.29%)	5(62.5%)	1 (33.33%)

DISCUSSION

CSOM is a long standing infection of a part or whole of the middle ear cleft. Clinically, CSOM is divided into two major types: Tubotympanic CSOM i.e. 'Safe' or 'Benign' type of CSOM and Atticoantral i.e. 'unsafe' or 'dangerous' type of CSOM. [2]

The definitive treatment of CSOM is by surgery (tympanoplasty and/or mastoidectomy), nevertheless, initial treatment by ear toilet and ototopical agents is necessary to prepare the ear for surgery. The selection of local or systemic antibiotic for therapy depends greatly on the type of the organism isolated in such cases.

In present study, microbial growth was seen in 176 (92.14%) samples out of 191 swabs used. 15 samples (7.8%) showed no growth. The culture results are found correlated with previous studies. [7-11] Negative cultures can be attributed to Non-bacterial growth, Anaerobic growth, Prior-antibiotic therapy and/ or Presence of antimicrobial enzymes i.e. lysozyme alone or in combination with immunoglobulins that suppress the bacterial growth. [4,10]

121 (68.75%) samples showed mono-microbial growth while 55 (31.25%) samples showed poly-microbial growth. Our study is correlated with Rama Rao et al. (1980) [3] found equal incidence of mixed and pure culture and Baruah et al. (1972) found predominance of mixed culture. [12]

In present study, most commonly affected age group was 31-45 years (34.66%) followed by age group 16-30 years (27.33%). In most of the earlier studies, the most commonly affected age group is 0-30 years. [13-18] The reason for high prevalence in higher age group in present study may be because of low socioeconomic status and poor awareness of the patients in villages near the hospital.

In the present study, Pseudomonas aeruginosa (38.63%) was the most commonly isolated bacterial pathogen followed by staphylococcus aureus (35.22%) and klebsiella sp. (10.22%).

Pseudomonas is the predominant cause of CSOM in tropical region does not usually inhabit the upper respiratory tract, its presence in the middle-ear cannot be ascribed to an invasion through eustachian tube and it should be considered as secondary invader gaining access to the middle-ear via tympanic membrane perforation. [19] Proteus mirabilis was seen in 9.65%% of the cases and Escherichia coli were isolated from 4.5% cases, and these findings were similar to the reports in earlier studies. [16,18]

In the present study the most effective antibiotic against Pseudomonas aeruginosa was found to be Vancomycin (94.11%) followed by amikacin (86.76%), piperacillin+Tazobactam, ceftazidime, netilmicin, Gentamicin, ceftriaxone and ciprofloxacin. This finding was corroborated by studies of numerous other authors. [13,18,19]

Staphylococcus aureus was found to be the second most common organism in the present study. The antimicrobial susceptibility pattern of Staphylococcus

aureus revealed highest sensitivity to piperacillin+tazobactam (88.70%) followed by amoxicillin+ clavulanate (77.41%), Vancomycin (75.80%), ceftriaxone & ceftazidime (70.96%), Netilmicin (67.74%) and Amikacin (61.29%) and least sensitivity to quinolones. In case of Klebsiella sp, Proteus, E.coli and Enterococcus faecalis-ceftriaxone, Amikacin and piperacillin with Tazobactam were found to be equally effective. These findings are in accordance with previous study done by Gulati et al (1997). [20]

CONCLUSION

A thorough and precise knowledge of the etiological agents causing CSOM and their antimicrobial susceptibility is of essential importance for an effective and efficient treatment and thus in further prevention of both complications and development of antibiotic resistance which is becoming more common now a days.

ABSTRACT

Background: *Hepatitis B infection is a major global health problem. The hepatitis B surface antigen (HBsAg) in serum is the first seromarker to indicate active HBV infection either acute or chronic. The seroprevalence of Hepatitis B surface antigen among general population attending OPD at a tertiary care hospital is useful in assessing true nature of problem, which can help to estimate the magnitude of HBV infection and aid in devising preventive measures. The aim of the study was to determine the seroprevalence of Hepatitis B infection among OPD patients attending a tertiary care hospital.* ***Methods:*** *Data from Dec 2015- April-2017 for OPD patients underwent HBsAg screening were collected and analysed.* ***Results:*** *A total number of 3891 patients were screened for HBsAg among them 1731 (44.48%) were males and 2160 (55.51%) were females. The seroprevalence of HBsAg in total OPD patients was 90(2.31%), was higher in males 46(2.65%) as compared to females 44(2.03%). The highest seroprevalence was found in 60-71 (4%) age group.* ***Conclusions:*** *The seroprevalence of Hepatitis B positive cases was 2.31% among OPD patients. Also, the rising seroprevalence rates of hepatitis B in males need urgent attention.*

Key words: *HBsAg, seroprevalence, OPD patients, tertiary care hospital*

INTRODUCTION

About 30% of the world population has serological evidence of current or past infection with hepatitis B virus. It is known to be the 10th leading cause of death and HBV related hepatocellular carcinoma is the 5th most frequent cancer worldwide.[1] About 2 billion people (or 30% of world population) worldwide have serological evidence of current or past HBV infection, and an estimated 350 million people harbor chronic infection[2]. India has been placed into the intermediate zone of prevalence of hepatitis B (2-7% prevalence rate by WHO).[2] Indian population forms the second largest global pool of chronic HBV infections and the number of HBV carriers in India is estimated to be 50 million.[3] The virus is transmitted by either per-cutaneous or mucous membrane contact with infected blood or other body fluid and is found in highest concentrations in blood and serous exudates. The primary routes of transmission are peri-natal, early childhood exposure, sexual contact, and per cutaneous exposure to blood or body fluids (i.e. injections, needle stick, blood transfusion). The hepatitis B surface antigen (HBsAg) in serum is the first seromarker to indicate active HBV infection, either acute or chronic.[4]

A large population of patients suffering from hepatitis B may be asymptomatic and can transit the disease to healthy population. The patients presenting to the OPDs of a hospital are generally those seeking treatment for mostly community acquired ailments hence the estimation of seroprevalence of hepatitis B surface antigen in such patients can be considered as a surrogate marker to represent the dynamics of virus transmission in the community. Studies have been conducted to estimate the prevalence of hepatitis B virus in selected group of people with higher risk factors such as blood donors, pregnant women, drug addicts and patients with liver disorders.

However, there is paucity of information in India on prevalence of HBV infection among general population. That is why a prevalence based study of patients at a

tertiary care teaching hospital is helpful in assessing true nature of problem in the community, which can help in assessing the magnitude of HBV infection and aid in devising preventive measures.

Community based seroprevalence studies are difficult to conduct in a developing country like India, because of socioeconomic hurdles and logistics difficulties. More than one half ambulatory and two- thirds outpatients care are catered by private health care in India.[5]

A private tertiary teaching hospital catering to the needs of a large population thus represents an important center for serological surveys. Also, the available data at Rajasthan state level on the seroprevalence and distribution of this blood borne pathogen is limited.

It was against the above backdrop that the present study was undertaken to estimate the seroprevalence of Hepatitis B viral infection among OPD patients attending tertiary care hospital.

METHODS

The present study is a prospective hospital based study conducted in the department of Microbiology, at Ananta Institute of Medical Sciences & Research Center, Rajsamand from December 2015 to April 2017. A total of 3891 blood samples were collected from patients attending different OPDs, for whom HBsAg detection was sought after a written consent. For the evaluation of HBsAg, a one-step rapid immunochromatographic Assay (ICA) was used. The qualitative detection of HBsAg was determined using a rapid Card (Hepacard-Biomed industries). The ICA are rapid and sensitive methods for detecting HBsAg. They are economical and do not require special instrumentation for analysis and have been recommended for use in clinical microbiology laboratories.[6] Immnunochromatoghraphic Assay has high sensitivity and specificity.[7] The reactive samples were retested in duplicates with fresh blood samples, if found reactive were considered as reactive.

RESULTS

We report here a study to assess the epidemiology of HBV prevalence among the OPD patients attending a tertiary care hospital of Rajsamand (Rajasthan).

A total of 3891 serum samples were processed for HBsAg detection over a period of 12 months, among them 1731 (44.48%) were male and 2160 (55.51%) were female. Table 2 shows age and sex distribution of hospital based population. The seroprevalence of HBsAg was 90 (2.31%). It was higher in males 46 (2.65%) as compared to females 44 (2.03%). The highest seroprevalence was found to be among 61-70 age groups which were (4%). The highest seroprevalence among HBsAg positive male was found in 61-70 age group which was 5.47% and among females were in age group 41-50 which was 3.71.

DISCUSSION

The seroprevalence of HBsAg in the present study was found to be 2.31%. India has been placed into the intermediate zone of prevalence of hepatitis B (2-7%) so present study findings correspond to it. HBV prevalence among the hospital based population at Karad, Maharashtra in a tertiary care hospital by Patil et al 2016,[8] the seroprevalence of HBsAg was found to be 2.25%. A study conducted by Tripathi P.c. et al 2015[9] seroprevalence of hepatitis B surface antigen at a tertiary care center in Telangna was 1.69%. Samtha P et al 2014[10] in their hospital based population at Guntur Andhra Pradesh reported prevalence of hepatitis B surface antigen was 2.4%, which approximately coincides with our study. Quadri S.A. at al 2013[11] reported the prevalence of HBsAg to be 1.63%, in a hospital based study at Bijapur, Karnataka. A recent study conducted in Rajasthan by Payal Mathur et al 2016[12] at a tertiary care teaching hospital situated at district Ajmer, the seroprevalence of HBsAg was found to be 0.94% only. Another hospital based population study conducted by Smita Sood 2013[13] at Jaipur district of Rajasthan at a superspeciality private hospital among OPD attendees, the prevalence of hepatitis B surface antigen was observed to be 1.73%. There are several studies conducted on seroprevalence of HBsAg in India. The point of hepatitis B in non-tribal population is 3.07% and among the tribal population is 11.85%. Batham A et al in their review of 54 studies on seroprevalence of HBsAg was observed 2.4% in non-tribal population and 15.9% among tribal population. Another review of hepatitis B prevalence in India by Lodha et al has conducted that it is in between 1-2%[14]. High prevalence of HBsAg (between 2-7%) has been reported in the past, and a community based study carried out in Tamil Nadu reported the prevalence of HBsAg was 5.7%.[15] Another study conducted in Sarkhet Valley, HBsAg prevalence rate was found to be 8.8% in the hospital patients.[16] The prevalence of HBsAg in patients attending surgical OPD at Fauji Foundation hospital, Rawalpindi, Pakistan has been reported as 2.28%.[17] Seroprevalence of Hepatitis B was 2.11% to3.53%[18, 19] in Rawalpindi, and 4% from Jamshoro (Sindh).[20] Very Low prevalence rate of HBsAg also has been observed in few studies Smita Sood and Shirish Malvankar 2010[21] in a study of HBsAg prevalence in hospital based population was noted to be 0.87%. The relative low prevalence in their study could be due to the fact that it was conducted in a private hospital catering usually to economically privileged class patients. Another low prevalence of 0.62% has been reported among blood donors from coastal Karnataka.[22]

Table-1 Gender Distribution of HBsAg Positive Patients

Gender	No. of sera tested	HBsAg positive sera	Percentage
Male	1731	46	2.65
Female	2160	44	2.03

Prevalence of Hepatitis B varies from country to country and depends upon a complex mixture of behavioural, environmental and host factors. In general, it is lowest in countries or areas with high standards of living (eg. Australia, North America, North Europe) and Highest in countries or area where socioeconomic level is lower (eg. China, South-East Asia, South America)[23] Most of the studies have reported high prevalence of HBsAg in males as compared to females, which is also true in our study.

Table -2 Age and Sex distribution of OPD patients with hepatitis B seropositivity

Age Group	Male	Female	HBsAg (+) Male %	HBsAg (+) Female%	Total Patients Tested	Total Patients HBsAg (+)%
0-10	36	18	0(0%)	0(0%)	54	0(0%)
11-20	80	74	2(2.5%)	0(0%)	154	2(1.29%)
21-30	338	739	8(2.36%)	8(1.08%)	1077	16(1.48%)
31-40	392	588	8(2.04%)	14(2.38%)	980	22(2.24%)
41-50	315	296	10(3.17%)	11(3.71%)	611	21(3.43%)
51-60	352	234	9(2.55%)	8(3.41%)	586	17(2.90%)
61-70	146	129	8(5.47%)	3(2.32%)	275	11(4%)
Above 71	72	82	1(1.38%)	0(0%)	154	1(0.64%)
Total	**1731 44.48%**	**2160 55.51%**	**46 2.65%**	**44 (2.03%)**	**3891**	**90 (2.31%)**

Smita sood and Shirish Malvankar have reported the prevalence to be 1.04% and 0.58%in males and females respectively.[21] Tripathi et al reported HBsAg prevalence in males 1.97% and in 1.28% females, Payal Mathur et al reported 1.12% in males and 0.7% in female, Samtha et al reported males 2.5% and 1.13% in females. There has been no plausible explanation for the higher rates in males in the general population but probably due to the higher exposure to occupational HBV, and also probably because females clear the HBV more efficiently as compared to males. In the present study, highest prevalence was found to be among 61-70 yrs age group i.e 4% followed by 41-50 i.e. 3.43% and 51-60 age group with 2.90%. Quadari et al reported relatively higher percentage of subjects in 6^{th}, 3^{rd}, and 2^{nd} decade of life respectively were found with HBsAg in their sera. Smita Sood and Shirish Malvankar reported highest prevalence among 2^{nd}, 5^{th} and elderly patients. Patil et al reported highest HBsAg prevalence among 51-60 yrs age group (5.24%) in both males (5.51%) and females (4.78%). A community based study carried out in Tamil Nadu reported that age specific prevalence for the overall exposure to HBV, HBsAg, HBeAg was not significantly different in different age group.[24] In another population studies, conducted on blood donors the HBsAg carrier rate is observed to increased directly with age up to a peak and then to decline among the older age group.[25]

CONCLUSION

Present study reported Seroprevalence of HBsAg as well as its age and sex wise distribution, our study highlights HBV infection rate in this part of the country and shall provide reference to future studies on the epidemiology of HBV infection, to understand and assess the magnitude of disease in a community and for its control and prevention. This study also shows that the ever rising Seroprevalence rates of hepatitis B among the males, is a cause of alarm in the country which also should be taken into consideration.

ABSTRACT

Background: The Human Immunodeficiency Virus (HIV) has changed from life threatening to chronic condition due to the almost universal use and accessibility of antiretroviral treatment (ART) among HIV patients. Antiretroviral (ARV) treatment works by suppressing the viral load and restoring the immune system. Once patients start Highly Active Antiretroviral Therapy (HAART), it is to be continued lifelong in spite of its many adverse side effects. **Objective:** To identify the adverse drug reactions (ADRs) to antiretroviral therapy (ART) and to assess their impact on treatment compliance in patients with HIV/AIDS in western India. **Methods:** A retrospective study was conducted in Gujarat to study the adverse effects after HAART initiation in 1244 patients on HAART who were evaluated retrospectively for their adverse drug reactions (ADRs). **Results:** The most common first line regimen was stavudine+lamivudine+efavirenz (d4T +3TC + EFV)(68.6 %) followed by stavudine + lamivudine + nevirapine (d4T + 3TC + NVP)(17.9%); zidovudine+ lamivudine + nevirapine(AZT+3TC+NVP) (10.9 %); and zidovudine+lamivudine+efavirenz

(AZT + 3TC +EFV) 2.5%. The first line of regimen was modified in 136(10.9%) patients, the most common cause for modifying therapy being development of an adverse effect 721(57.9%) and completion of antituberculous therapy in 510 cases(41.%). The most common cause for modifying therapy was skin rashes due to NVP in 279(22.4%) followed by loss of appetite 195(17.2%). **Conclusion:** A significant proportion of patients had adverse effects of HAART. A significant proportion of those started on NVP-based regimens are more likely to substitute therapy when compared with those on non-NVP-based regimens.

INTRODUCTION

The Human Immunodeficiency Virus (HIV) has changed from life threatening to chronic condition due to the almost universal use and accessibility of antiretroviral treatment (ART) among HIV patients [1]. Antiretroviral (ARV) treatment works by providing suppression of viral load and restoring the immune system. It is estimated that out of the 35.3 million people living with HIV worldwide, 10.6 million were receiving ART in 2012 [2]. Nearly, 6.6 million HIV/AIDS related deaths worldwide have been prevented as a result of ART [2]. Despite these gains, adverse reactions to these medicines remain a significant public health concern and may compromise the effectiveness of the ART programmes [3,4].

In India, approximately 2.4 million people were living with human immunodeficiency virus (HIV) in 2009, which is estimated to be the third largest population of HIV affected people in the world.[5] With the availability of new antiretroviral drugs, there has been a decline in morbidity and mortality due to acquired immunodeficiency syndrome (AIDS).

The advent of highly active antiretroviral therapy (HAART) has resulted in significant decreases in HIV-related morbidity and mortality in both the developed and developing

world[6-8] and HAART has been touted as one of the greatest breakthroughs in the response to the HIV pandemic. HAART may be modified or interrupted as a result of many reasons, key among which are adverse effects and virological failure [8-11]. The adverse effects may in themselves result in virological failure or disease progression as a result of sub optimal dosing or treatment interruption.

In a study done in India, 90.6% of all the patients on HAART developed an adverse drug reaction and there were 618 episodes in various systems, the abdominal and central nervous systems were the most affected [12]. Luma and colleagues, studying patients in Cameroun found an adverse drug reaction (ADR) prevalence of 19.5% of which 21.2% were due to peripheral neuropathy. Overall 56.1% of ADR were attributed to the use of stavudine (d4T)[13]. Anaemia was observed as an ADR in many patients on ART, especially whenever the patients took zidovudine (ZDV) [14].

In an effort to scale up HAART to those who needed it most, the WHO in 2003 launched the "3 by 5" initiative with an objective of placing 3 million persons living with HIV on HAART by 2005[15]. In line with this initiative the World Health Organisation (WHO) developed guidelines on antiretroviral therapy for resource poor countries. The guidelines recommended a combination of two nucleoside reverse transcriptase inhibitors (NRTIs) and one non-nucleoside reverse transcriptase inhibitor (NNRTI) as first-line regimens in resource-constrained settings[16].

Access to antiretroviral therapy (ART) has improved tremendously over the last few years due to implementation and enforcement of various strategies by National AIDS Control Organization (NACO). NACO has established ART centres in selected government hospitals which offer free treatment for HIV/AIDS and related opportunistic infections. [17] In India, as of May 2009, there were 174 ART centres and 1,55,000 patients were on therapy. [18] By 2012, National AIDS Control Program III (2007-2012) aims to increase number of ART centres up to 250 where 3,00,000 adults will be given free ART. [17] In addition, 10 centres of excellence responsible for training, research work and mentoring of ART centres linked to them have been established across the country.[19]

HAART is the corner stone of management of patients with HIV/AIDS infection. [20] Consistent use is vital for drugs to be effective and to prevent emergence of resistance. However, ARV drugs are highly toxic and are associated with various adverse

drug reactions (ADRs) due to which many patients require withdrawal of the drug or even discontinue the treatment resulting in treatment failure. [21] Hence, monitoring and reporting of ADRs in HIV/AIDS patients receiving ART assumes great importance. There is paucity of data on ADRs to ART in Indian population. Keeping this in view, the present study was designed to identify the ADRs in patients receiving ART and to assess their impact on the compliance to the prescribed treatment.

MATERIAL AND METHODS

It was a retrospective study conducted at various ART centres of western India. The study was approved by GSACS, Ahmedabad.

A cross sectional retrospective study was conducted reviewing data of 1244 patients initiated on HAART. Univariate analysis was done for the dependent and independent variables. Stepwise logistic regression procedures were used to model the effect of gender on the development of ADRs controlling other variables like age, marital status, weight at baseline and CD4 at baseline.

From the patients records, findings of complete general, physical, systemic examination and all laboratory investigations were recorded. ADR monitoring was done in a systemic manner adopting both spontaneous and intensive monitoring approaches. The WHO definition of an ADR was adopted [22]. A pre-designed and pre-tested proforma had been confidentially used for ADR record keeping.

If the patient developed any ADR, the drug which was most commonly implicated in the causation was challenged by the treating physician and was replaced by another drug from the same class. The patient was then monitored for recovery from the symptoms.

The World Health Organisation (WHO) ADR probability scale was used for causality assessment.

With respect to ADR, following parameters were recorded.

1. Number of adverse drug reactions with different treatment regimens,
2. Nature of adverse drug reactions,
3. Severity of adverse drug reactions,

4. Incidence of each adverse drug reaction-calculated by dividing the number of patients suffereing from a particular adverse drug reaction by the total number of patients taking the same suspected drug,
5. Requirement of de-challenge,
6. Compliance to the prescribed treatment- monitored by pill count at each visit and as reported by the patient, and
7. Number of deaths.

RESULTS AND DISCUSSION

One thousand two hundred forty four (1244) patients who had been on ART were included in the present study, Out of which 1132(90.99%) patients complained of ADRs and few of them even recorded to have multiple ADRs.

Patients received four first line regimens as per the NACO guidelines [Table 1]. Stavudine +Lamivudine + Efavirenz was the most widely used combination [Table 2]. Drugs were given in the following dosages: Stavudine 40 mg B.D., Lamivudine 150 mg B.D., Nevirapine 150 mg B.D., Zidovudine 300 mg B.D. and Efavirenz 600mg H.S.

Out of the 1244 patients enrolled, 1132(90.99%) patients were recorded to report ADRs. About 74.91 % were recorded to develop more than one adverse reaction. A total of 1511 adverse drug reactions affecting various systems were observed in 1132 patients [Table 3]. Majority of adverse reactions were observed related to the gastrointestinal system and central nervous system including loss of appetite and insomnia each accounting for 28 percent. Maximum adverse reactions (872 out of 1511) were observed in patients who were prescribed treatment Ia (Stavudine + Lamivudine + Nevirapine). This was followed by 338 ADRs in patients receiving treatment regimen IIa, 223 ADRs in the patients taking treatment regimen I, and 78 ADRs in the patients taking treatment regimen II.

Irregular menstrual cycle was reported by 10 patients, 3 each in treatment I, II, and IIa. Loss of smell sensation and hearing impairment was observed in 2 patients receiving treatment regimen I and in 3 patients in regimen Ia.

Incidence of ADRs to a particular drug was calculated based on only the dechallenge test. Incidence of peripheral neuropathy and fat redistribution due to stavudine was 6.98% and

2.67%, respectively, and incidence of skin rash due to nevirapine was 7.23%, incidence of hepatitis due to nevirapine and efavirenz was 2.96% and 2.17 % respectively.

Even though HAART showed plenty of adverse drug reactions, at the same time it decreased morbidity and mortality in HIV/AIDS patients, it improved health status, body weight and even CD4 counts in almost about 90 % of the patients who adhere to this treatment strictly [Table 4].

The basic configuration of antiretroviral regimens is unchanged. The most common initial regimens are a non-nucleoside reverse transcriptase inhibitor (NNRTI) or a protease inhibitor (PI) with two nucleoside/nucleotide reverse transcriptase inhibitors (NRTIs). Common toxicities of ART can make adherence to therapy difficult. However, adherence is important to prevent the development of drug resistance. Unlike therapy for other diseases, a strategy of decreasing the dose or switching to a different drug to minimize toxicity and maximize adherence may not be possible with ART; the benefit of suppressing HIV may override other considerations. Identification and awareness of ART toxicity are necessary to facilitate patient adherence and determine when a change in therapy may be needed.

Routine monitoring in patients receiving ART includes a complete blood count and a comprehensive metabolic panel every three to six months. A lipid profile and urinalysis for proteinuria should be performed annually. When ART is changed, a complete blood count, metabolic panel, and lipid profile should be performed two to eight weeks afterward. Abnormal results should prompt more frequent testing based on clinical assessment.

According to Joint United Nations Programme on HIV and AIDS (UNAIDS) and WHO estimates, approximately 1,58,000 people all over the world were receiving ART in 2007[23]. It is well known that anti-retroviral drugs are highly toxic and therefore, early detection of ADRs by continuous monitoring is indispensable for successful treatment. In the present study, 1511 ADRs were observed in 1132 (90.99%) patients. Main risk factors associated with development of ADRs in HIV patients as determined by the researchers in previous studies included illiteracy, female gender, CD4 < 200 cells/µL, and opportunistic infections such as tuberculosis.[24] Earlier studies have also documented that a majority of ADRs were predictable and preventable.[24,25]

We observed that the maximum numbers of ADRs were related to the gastrointestinal system which is in agreement with findings of Modayil *et al*.[24] In our study, apparently maximum ADRs occurred in patients receiving stavudine+lamivudine+efavirenz which may be attributable to larger number of patients receiving this combination; however, it was observed that the incidence of ADRs was highest with the stavudine+lamivudine+nevirapine regimen.

Most cases (18/21) of peripheral neuropathy and all cases of lipodystrophy were observed in patients receiving stavudine therapy. Similar findings have been reported earlier. [24] We observed an incidence of 1.39% of peripheral neuropathy but no case of fat redistribution with stavudine. However, earlier studies have reported an incidence of peripheral neuropathy as 10%, 12% and a prevalence of lipodystrophy as 25%.[26,27.28] Low incidence seen in our study may be contributed to under diagnosis and that the drug is well tolerated in this part of the world. Recently updated WHO guidelines on ART for HIV/AIDS patients do not recommend use of stavudine as a first choice in first-line regimens due to these adverse effects.[20]

Incidence of skin rash (18.46%) and hepatotoxicity (3.19%) due to nevirapine seen in our study was almost the same when compared to that observed by Rotunda *et al*. (skin rash-15%),[29] Martinez *et al*. (hepatotoxicity-12.5%),[30] and Sulkowski *et al*. (hepatotoxicity-15.6%).[31] Latter also reported that the incidence of hepatitis due to efavirenz was 8%, whereas we found an incidence of only 0.43%. Further, in our study dechallenge with nevirapine and efavirenz in these patients resulted in resolution of hepatitis gradually over a period of 3 weeks and 1 month, respectively.

Few ADRs never documented earlier in the literature with use of ART such as irregular menstrual cycle, hearing impairment and loss of smell were also observed in the present study.

Issue of non-compliance is of major concern in management of HIV patients keeping in view that it requires lifelong treatment. Non-compliance causes significant economic implications by complicating disease management and its subsequent healthcare and social costs. Earlier studies have documented that most important factor resulting in non adherence to ART is toxicity.[32] We observed that it was mainly the severe ADRs which affected the patients' compliance. We observed that 22.1% of patients were non-compliant to ART because of

ADRs. These findings are in concordance with that of Monforte *et al.* who reported non compliance in 21.1% of Italian patients due to ADRs to ART.[32]

The risk of adverse drug reactions (ADRs) arises because of the effect of the disease on the immune systems and the safety profiles of the complex ART drugs [3]. There are a number of ADRs related to ART that have been documented, and may be mild to severe; and short to long term depending on the environment[1,5,33]. ADRs in developing countries may differ from those in developed countries because of high prevalence of conditions such as malnutrition, tuberculosis and patients presenting with advanced HIV disease [34]. For instance, it has been found that in Africa, neuropathy, neutropenia and lipodystrophy are the predominant ADRs[35]. Short term ADRs are a potential threat to successful initiation and adherence to ART[36]. The timing of ADRs may also depend on the type of drugs. Studies have shown that patients on Efavirenz, Lamivudine and Zidivudine or Indinavir, Zidovudine and Lamivudine may present with ADRs within the first 12 and 24 weeks, respectively[37]. ADRs may be common or specific to class of drugs [1,36]. Drugs classified as non-nucleoside reverse transcriptase inhibitors (NNRTIs) which include Efavirenz (EFZ) and Nevirapine (NVP) are known to cause rashes and hepatotoxicity. On the other hand, drugs classified as nucleoside reverse transcriptase inhibitors (NRTIs) including Zidovudine (AZT) and Stavudine (d4T) are known to cause anaemia, nausea, rashes, lipoatrophy and lactic acidosis.[1]

Apart from ADR depending on the environment and the type of ART regimen, a number of other risk factors have been identified, that include patient age, gender, duration of treatment, disease biomarkers such as CD4 count and viral load and body mass index (BMI) [38]. These risk factors have been found to interact with type of ADR. For instance, females are more likely to develop rashes and hepatotoxicity[38]; and patients aged 40 years and above are at a higher risk of developing peripheral neuropathy when taking d4T[39]. The longer a patient is on ART the less likely they would experience ADRs; possibly as a result of stability in ARV regimen, coming after many changes and eventually settling on an acceptable regimen [30].

Monitoring safety and toxicity related to ART remains a challenge facing the public health sector. Monitoring is usually done using spontaneous surveillance of HIV patients on treatment. Spontaneous reporting of ADRs is a very inefficient system in detecting drug-related conditions, leading to underestimation of the burden due to ADRs [3,40]. Thus, more systematic and robust surveillance methods including structured surveillance

pharmacovigilance systems, which assess and monitor safety profile and impact of antiretroviral medicines have been advocated. Structured surveillance tracks HIV positive patients who are on ART to assess drug related morbidity and mortality over time. South Africa, a country heavily hit by the HIV epidemic, uses spontaneous surveillance of HIV patients on ART to assess ART-related adverse effects. Though these data are routinely available, the coverage may not be adequate. Thus, for the purposes of this study, data from a structured surveillance system in Western India are used.

The adverse drug reaction events in patients often are of recurrent nature, such that the repetitions tend to cluster more in some patients than in others. Analyses of these data are complicated due to the fact that independence between the recurrent event times cannot be predicted in a subject. In medical studies, time-to-event models have been developed to account for possible dependence between recurrent events data [42]. The aim of this study was to provide a unified analysis of recurrent ADR events data from a structured antiretroviral pharmacovigilance surveillance system.

Table 1: Treatment Regimens as per NACO guidelines.

Treatment Regimens	Drugs in combination	No Patients
I	Zidovudine + Lamivudine + Nevirapine	136
Ia	Stavudine + Lamivudine + Nevirapine	223
II	Zidovudine + Lamivudine + Efavirenz	31
IIa	Stavudine + Lamivudine + Efavirenz	854

Table 2: Patient's characteristic in different treatment groups.

	Treatment regimen I	Treatment regimen Ia	Treatment regimen II	Treatment regimen IIa
No of patients	136	223	31	854
Mean Age(years)	36 + 8.34	40 + 2.87	33 + 7.20	38 + 4.31
Sex(M/F)	92/44	155/68	20/11	532/322
Weight (kg)	50 + 6.65	53 + 9.22	51 + 5.13	58 + 5.22
Current CD4 count				
< 200	43	78	21	247
> 200	93	145	10	607

Table 3: ADRs related to different systems.

System Involved	No. of patients with ADRs (%)
Gastrointestinal system	**678(36.45%)**
Loss of appetite	195(28.76%)
Dyspepsia	154(22.71%)
Abdominal Discomfort	81(11.94%)

Diarrhoea	74(10.91%)
Constipation	54(07.96%)
Nausea	51(07.52%)
Vomiting	43(06.34%)
Abdominal Pain	21(03.10%)
Hepatitis	05(00.59%)
Central Nervous System	**415(22.31%)**
Insomnia	111(28.75%)
Headache	89(21.45%)
Dizziness	78(18.80%)
Anxiety	57(13.73%)
Nightmare	27(06.51%)
Peripheral neuropathy	21(05.06%)
Excessive sleep at night	19(04.58%)
Delusion	14(03.37%)
Dermatological	**287(15.43%)**
Skin rashes & itching	279(97.21%)
Facial discolouration	08(02.79%)
Metabolic	**178(09.57%)**
Fatigue	109(61.24%)
Dyspnea	69(38.76%)
Musculoskeleton	**106(05.70%)**
Body ache	51(48.11%)
Vague chest pain	28(26.41%)
Pain in legs	27(25.47%)
Miscellaneous	**15(00.81%)**
Irregular menstruation	10(66.67%)
Loss of smell sensation	3(20.00%)
Hearing impairment	2(13.33%)

Table 4: Descriptive analysis of socio-demographic and health status of the patients at ART clinic.

	Variables	**n(%), N = 1244**
1	**Socio-demographic**	
(i)	Education (primary and above)	871(70.1)
(ii)	Work status (unemployed)	247 (19.9)
(iii)	Age (≤40 years)	705(56.7)
(iv)	Gender (female)	445(35.8)
(v)	Marital status (married)	1068 (85.9)
(vi)	Residency (urban)	466 (37.5)
2	**Clinical variables**	
(i)	Duration of ART (≤4 years)	495(39.8)
(ii)	Current CD4 level (cells/mm^3)	
a.	< 200	389(31.3)
b.	>200	855(68.7)
(iii)	Non adherence	47(3.8)
3	**General profile**	
	General health at the start of treatment	

(i)	Healthy	257(20.67)
(ii)	Mild to severely ill	987 (79.5)
4	**CD $_4$ count after treatment**	
(i)	Increased	1135 (91.2)
(ii)	Decreased	27(2.1)
(iii)`	No change	82(6.6)
5	**Health status after ART start**	
(i)	Improved	1114(89.5)
(ii)	Not improved	130(10.4)
6	**Body weight**	
(i)	Increased	1009(84.1)
(ii)	Decreased	91(7.3)
(iii)	No change	144(11.6)

CONCLUSION

HAART has decreased morbidity and mortality up to the expectation along with increasing considerable longevity of life of the HIV/AIDS patients. But all these antiretroviral drugs are highly toxic and associated with myriad adverse drug reactions and that too with a very high frequency. These ADRs are adding to the problem of non-compliance which in itself is a very big issue with ART. Hence, it is prudent to recognize these ADRs as early as possible in the course of treatment. This goal can be achieved by regular monitoring and reporting of ADRs which is indispensable for improving the treatment outcome.

ABSTRACT

Background: To detect the prevalence rate of bacterial infection among urinary isolates and to determine the antimicrobial susceptibility pattern in the rural area of Rajsamand. **Aim:** of the study was to find prevalence of uropathogen in this part of world along with to study the antibiogram of UTI cases. **Material and Method:** A retrospective analysis of bacterial pathogens and their antimicrobial susceptibility was done on urine sample s at tertiary care hospital. Antimicrobial susceptibility tests were done using disc diffusion technique as per the standard of Kirby-Bauer method. **Results:** Out of total 600 samples, 193 samples were found positive. Out of which males 74(38%) and females119(62%) were positive. Females showed higher prevalence rate of UTI than males. Gram negative bacteria were found in high prevalence rate than gram positive bacteria. E. coli 101(52 %) was the most common organism, followed by Klebsiella 25(13%), CoNs22(11%), Pseudomonas13(7%), CoPs11(6%), Enterococcus12(6%) Candida Sp. 6(3%) and Proteus Sp. 3(2%). **Conclusion:** There is a need for constant monitoring of susceptibility of specific pathogens in different populations to commonly used anti-microbial agents.

KEYWORDS: Urinary tract infection, Antibiotic Susceptibility Pattern, Uropathogenes.

INTRODUCTION

Urinary tract infection (UTI) is an important health-care problem affecting millions every year in the community and tertiary care settings. It is a term applied to a variety of clinical conditions ranging from asymptomatic presence of bacteria in the urine to severe of the kidney with sepsis.[1]

A count of $>10^5$ colony forming units (CFU)/mL of urine is considered as significant bacteriuria.[2] Etiological agents of UTI are variable and usually depend on time, geographical location and age of patients.[3] Most UTIs are caused by Gram-negative bacteria like Escherichia coli (E. coli), Klebsiella spp., Proteus mirabilis, Pseudomonas aeruginosa, Acinetobacter spp., and Serratia spp. and Gram-positive bacteria such as Enterococcus spp. and Staphylococcus spp[3]. E. coli is the single most common pathogen accounting for 70-75% of all cases of UTI.[2]

The antimicrobial agents used in treatment of UTI include cell wall inhibitors like Penicillin, Cephalosporins, DNA gyrase inhibitors like Floroquinolones and Aminoglycosides that are protein synthesis inhibitors. Inappropriate and extensive use of antibiotics has lead to the development of multidrug resistance among the pathogens. To ensure appropriate treatment, knowledge of the organisms that cause UTI and their antibiotic susceptibility pattern is mandatory.

MATERIAL AND METHOD

The study was conducted in a tertiary care hospital, Rajsamand, Rajasthan. All positive urine culture and sensitivity reports of males and females over a period of one year were included in the study. Urine culture and sensitivity reports with more than one causative organism were excluded from the study Sample size. The organism isolated and the antimicrobial susceptibility profiles were collected from the registration records using a standard data collection form.

Culture and Identification

As per the standard operating procedures, clean-catch midstream morning urine specimen were collected under

sterile conditions in a sterile wide mouth container. All samples were completely processed within 1–2 h after arrival, to avoid overgrowth of any contaminating bacteria. Urine samples were plated on Nutrient agar, Blood agar and MacConkey agar using calibrated wire loops and then incubated aerobically at 37 °C for 24 h. From positive cultures, uropathogens were identified based on biochemical reaction.[4]

Antimicrobial susceptibility tests

According to the standard operational procedures, antimicrobial susceptibility tests were done on Mueller-Hinton agar (Oxoid, Hampshire, England) using Kirby-Bauer disk diffusion method[8] antimicrobial agents of variable strength. Resistance data were interpreted according to Clinical laboratory Standards Institute. Reference strains of E. coli ATCC 25922 and Staphylococcus aureus ATCC 25923 (S. aureus) were used for quality control for antimicrobial susceptibility tests.[9] Statistical Analysis: Data entry was done using Microsoft Excel and the data was analysed using SPSS 16.

RESULTS

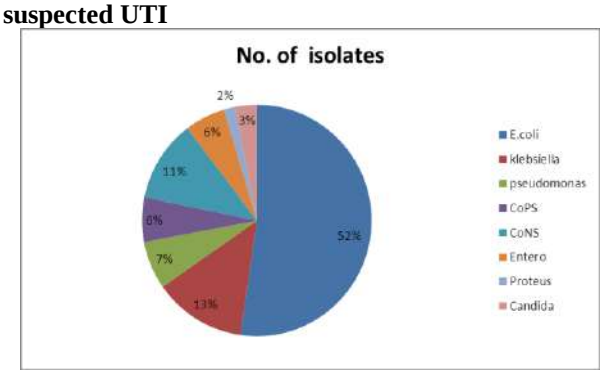
A total of 600 samples were taken during a period of 2015 -2016, out of which 193 were culture positive cases. The identification of bacteria and culture and sensitivity was carried out for the same. Out of 193 cases, males were 74 (38%) and females were 119(62%) and more common in 21-40 age group. The number of organisms isolated from females subjects were more than males (Table 1). E. coli 101(52 %) was the most common organism, followed by Klebsiella 25(13%), CoNs 22(11%), Pseudomonas 13(7%), CoPS 11(6%), Enterococcus 12(6%) Candida Sp. 6(3%) and Proteus Sp.3(2%). Sex-wise distribution of UTI by organism, Out of 74 males E. coli was isolated from 34 and Klebsiella 14 and out of 119 females E. coli was isolated from 65 and Klebsiella 11.E.coli (52%) , followed by Klebsiella (13%) were the commonest in both sexes (Table 4).The antibiotic susceptibility profile of gram negative organisms showed that E.coli and klebsiella were highly susceptible (100%) to imipenem followed by Nitrofurantoin, Amikacin, Piperacillin tazobactum, Ceftazidime/clavulanic acid while its resistance profile showed that they were more resistant to sulphamethoxazoles followed by amoxclav, ampicillin sulbactum, cephalosporins, and ceftriaxone. Staphylococcus aureus and Enterococcus were highly sensitive to Nitrofurantoin followed by Vancomycin, Linezolid, Gentamicin, Ciprofloxacin, Levofloxacin, Cotrimoxazole and Cephalosporins.

Table 1: Age and Sex distribution of patients with suspected UTI.

Age Group	Male	Female	Total
0-20	10	15	25
21-40	20	55	75
41-60	16	33	49
61-80	26	14	40
81-100	02	02	04
Total	74(38%)	119(62%)	193

Out of total 600 urine culture, 193 cases were culture Positive and sensitivity was also carried out for the same. Out of 193 cases, males were 74 (38%) and females were 119(62%) and more common in 21-40 age group. (Table.1).

Bacterial isolates from urine sample of patients with suspected UTI



E. coli 101(52 %) was the most common organism, followed by Klebsiella 25(13%), CoNs22(11%), Pseudomonas 13(7%), CoPs11(6%), Enterococcus 12(6%) Candida Sp. 6(3%) and Proteus Sp. 3(2%).

Table 2: Age- Sex distribution of patients with suspected UTI according to type of uropathogen.

Organisms	0-20		21-40		41-60		61-80		81-100		Total (n=193)
	Male	Female	Male	Female	Male	Female	Male	Female	Male	Female	
E.coli	4	9	8	26	9	20	15	9	-	1	101
Klebsiella	3	2	3	4	4	4	4	1	-	-	25
Pseudomonas	1	-	2	4	-	3	1	1	1	-	13
Proteus sp.	-	-	-	-	-	-	1	2	-	-	3
Cons	-	4	2	9	2	2	2	1	-	-	22
Cops	-	-	-	9	-	1	2	-	-	-	12
Enterococcus	2	-	4	3	-	1	-	-	1	-	11
Candida	-	-	1	-	1	2	1	-	-	1	6

According to Age-Sex distribution of Patients, Out of 74 males E. coli was isolated from 34 and Klebsiella 14 and out of 119 females E. coli was isolated from 65 and Klebsiella 11.(Table 2).

Table 3: Resistant pattern of Antibiotic in bacterial isolates from patients with suspected UTI.

Organisms	E.coli (n=101)	Klebsiella (n=(25)	Pseudo monas (n=13)	Proteus sp. (n=3)	Cons (n=22)	Cops (n=12)	Entero Coccus (n=11)

Co trimoxazole	78(77%)	17(68%)	13(100%)	03(100%)	13(33%)	04(33%)	08(73%)
Linezolid	NA	NA	NA	NA	0	0	0
Aztreonam	61(60%)	19(76%)	10(77%)	02(67%)	NA	NA	NA
Imipenam	02(2%)	0	0	0	NA	NA	NA
Meropenam	02(2%)	0	0	0	NA	NA	NA
Nitrofurantoin	04(4%)	06(24%)	13(100%)	03(100%)	03(14%)	0	01(9%)
Clindamycin	NA	NA	NA	NA	11(50%)	0	NA

The overall susceptibility profiles of bacterial isolates are shown in Table 3. Amongst gram negative bacilli, amox-clav and cefuroxime had the highest overall resistance followed by Ampicillin -Sulbactam, Cefixime, Ceftizoxime, Co trimoxazole whereas other drugs showed sensitive pattern. Cephalosporins were most resistant drugs in gram positive bacilli followed by amox-clav, Azithromycin, Ampicillin- Sulbactam, Co trimoxazole, Ciprofloxacin, Levofloxacin, Clindamycin, Nitrofurantoin.

DISCUSSION

Urinary tract infection is huge burden on health care due to high prevalence of infection in both community and nosocomial settings. It is caused by variety of pathogens including *E. coli*, *K. pneumoniae* and *P. aeruginosa*. Continuous surveillance of antibiotic susceptibility patterns of uropathogens at local level is crucial in dealing with emerging problems of antibiotic resistance and provides assistance in managing effective initial therapy.[4] In present study, the prevalence of UTI in females is higher than the males which is attributed to factors like close proximity of the uretheral meatus to the anus, shorter urethra. This finding is consistent with other studies done by Jubina Bency et al Prakasam A., K.C et al and Azra S. Akram T et al. There was significant growth of E.Coli, Klebsiella, Enterococci, Staphylococcus and Pseudomonas. Ecoli & Klebsiella infections were most common organisms similar to Jubina Bency et al. *Enterococcus* was sensitive to Vancomycin & Linezolid. *Staphylococcus* was sensitive to Vancomycin.[6] The pattern of antimicrobial resistance of the micro-organisms causing UTIs vary in their susceptibility to antimicrobials from place to place and from time to time. World wide data shows that there is an increasing resistance among UTI pathogens to convential drugs. Resistance has emerged even to newer more potent antimicrobial agents.

E.coli(52 %) was the most common organism, followed by Klebsiella(13%), CoNs(11%), Pseudomonas(7%), CoPs(6%), Enterococcus(6%) Candida Sp. (3%) and Proteus Sp.(2%). This finding patterns were similar with the study of Savitha like E.coli(48.04%), Klebsiella species(8.82%) and Proteus spp.(4.90%).

It has been observed that there is slow but persistent decrease in the sensitivity of gram negative and gram positive bacteria to some quinolones derivative, Ampicillin and Sulphonamides which is alarming because these antibiotics have been one of the best options for treatment of UTI in both outdoor patients and hospitalized patients. Other factors which may influence

the sensitivity of urinary pathogens includes, routes of administration, dosage schedule, choice of antibiotic, misuse of antibiotic and condition of patients and self-medication.[7]

CONCLUSION

In this study, higher prevalence rates of urinary bacterial isolates are observed in females the most commonly found organisms were *E. coli* and *Klebsiella*. There is an emerging resistance of commonly isolated bacteria to routinely used antibiotics, which can be ascribed to inappropriate antibiotic administration. Important infecting organisms are found to be the commensals of perianal and vaginal regions, emphasizing a need to have proper hygienic practices.

ABSTRACT

Background: Bacteria associated with blood stream infections are an important public health problem which results in morbidity and mortality globally. Emergence of multidrug resistant isolates in hospitalized patients is a major problem. Automation techniques play a major role in early identification of the isolate and its drug susceptibility testing which is important for better outcome of the treatment. This study was aimed to detect the blood stream isolates and their drug susceptibility pattern in hospitalized patients.
Methods: This was a retrospective study conducted from 377 records of automated blood culture (bact/alert) and drug susceptibility testing (vitek) results. Positive blood culture bottles were sub cultured to different culture media and the isolates were identified and screened for drug susceptibility testing on Vitek II.
Results: Around 20.68% of samples were positive for blood stream infections caused by different pathogens. A total of 78 microorganisms were isolated from 377 samples. Among which gram negative bacilli was observed in 52.56%, gram positive cocci in 44.87% and yeast in 2.56% samples. Coagulase negative *staphylococci* and *Klebsiella pneumoniae* were the predominant isolates of the study.
Conclusions: Early diagnosis of blood stream infections in hospitalized patients is life saving. Hence a continuous monitoring of isolates and their drug susceptibility is the need of the day.

Keywords: Blood stream infections, Coagulase negative *staphylococcus, Klebsiella pneumoniae*

INTRODUCTION

Blood stream infection (BSI) remains one of the foremost important causes of morbidity and mortality globally. The infection may range from self limiting to life threatening sepsis.[1,2] As case fatality rate is high it requires appropriate and immediate antimicrobial therapy. Different bacteria were associated with (BSI) from time to time at different geographical areas. These bacteria play an important role in causing mortality, increasing the length of hospital stay and also the health care cost.[3]

Drug resistance of these bacteria is an important issue of public health concern. Since many studies have reported that gram negative and gram positive bacteria are associates with these infections which are often drug resistant. Empirical antibiotic therapy is initiated in almost all cases before the blood culture reports are available. Choice of right empirical therapy is important. An early blood culture report may help in selection of appropriate antibiotics.[2,4]

Minimal time is required to get a blood culture report using automated systems. The etiology and antimicrobial pattern of (BSI) may vary at different times in the same region hence a continuous update is essential for epidemiological purpose and also for rational and accurate use of antibiotics by clinicians. The present

study aimed to determine the etiology and antibiotic resistance pattern in blood stream infections.

METHODS

Study design

A retrospective study was conducted from the records of automated blood culture (bact alert) and drug susceptibility testing (vitek) results in the clinical microbiology laboratory from June, 2016 to July, 2018 at Ananta institute of medical sciences and research centre, Rajsamand. This data includes 377 records of hospitalised patients who were admitted to different units of hospital during the study period.

Sampling technique and data collection

Blood cultures were performed for different age groups up to 90 years. Samples were collected by phlebotomist from the patients after disinfection of vein puncture site with 70% alcohol. 3-4ml of blood was inoculated in 30ml BacT/Alert blood culture bottles for paediatrics and 4-5ml blood was inoculated in 30ml BacT/Alert blood culture bottles for adults. These bottles were incubated in BacT/Alert automated system. The bottles which showed positive signal for growth were removed from the automated system and subculture was done on Nutrient agar, blood agar and MacConkey's agar. Smears from the colony of different agar plates were prepared and stained with Gram stain to identify the growth (i.e. gram positive or gram negative bacteria). Then the growth of the bacteria was run on VITEK II automated system for identification of the organism and Antibiotic Sensitivity. If there is no growth of bacteria within five days of inoculation of blood sample into BacT/Alert blood culture bottle then the sample is considered to be negative.

Data regarding the age, sex, isolate and its antimicrobial pattern was collected and statistical analysis of the data was done by Chi square test to study the P value using social science statistics online software.

RESULTS

A total of 377 samples were screened for blood culture from hospitalized patients of different units. 20.68% of samples were positive for blood stream infections caused by different pathogens (Table 1).

A total of 78 microorganisms were isolated from 377 samples. Among which gram negative bacilli was observed in 52.56%, gram positive cocci in 44.87% and yeast in 2.56% samples. The leading isolate among the gram positive cocci were CONS (coagulase negative *staphylococci*) and among the gram negative bacilli, *Klebsiella pneumoniae*. Details of each isolate were mentioned in Table 1. Only two samples were found to be positive for yeast i.e. *Candida tropicalis*.

Table 1: Bacteria and yeast isolated from blood culture samples.

	Isolate	Positive %
Gram negative bacilli (A)	*Acinetobacter baumannii*	4 (9.75%)
	Acinetobacter iwoffii	1 (2.44%)
	Burkholderia cepaciae	1 (2.44%)
	Escherichia coli	10 (24.39%)
	Enterobacter cloacae Complex	2 (4.87%)
	Klebsiella pneumoniae	17 (41.46%)
	Pseudomonas aeruginosa	3 (7.31%)
	Spingomonas paucimobilis	1 (2.44%)
	Stenotrophomonas maltophilia	1 (2.44%)
	Serratia marcescenes	1 (2.44%)
Total		41 (100%)
Gram positive cocci (B)	*Staphylococcus aureus*	3 (8.57%)
	Staphylococcus cohnii#	2 (5.71%)
	Staphylococcus epidermidis#	6 (17.14%)
	Staphylococcus haemolyticus#	4 (11.48%)
	Staphylococcus hominis#	3 (8.57%)
	Staphylococcus lentus#	2 (5.71%)
	Staphylococcus pseudintermedius#	2 (5.71%)
	Enterococcus faecalis	3 (8.57%)
	CONS	10 (28.57%)
Total		35 (100%)
Yeast (C)	*Candida tropicalis*	2(100%)
Total (A+B+C)		78/377* (20.68%)

*Total number of samples tested, CONS-coagulase negative *staphylococcus*, # CONS

Isolates were predominant in males (62.82%) as compared to females (37.18%) (Table 2). Paediatric patients were more (31.57%) exposed to BSI than adult and elderly patients (23.52%). Statistical analysis showed a P value of 0.03. CONS were the leading pathogens in paediatric patients. *Klebsiella pneumoniae* was the leading pathogen among the adult and elderly patients. 83.3% (65) of samples were culture positive in <24hours, 15.4% (12) in between 24 <48hours, 1.3% (1) between 48-72hours.

Table 2: Sex wise and age wise distribution of positive and negative blood culture samples.

Variable	Blood culture result			P value
	Positive	Negative	Total	
Male	49	191	240	X^2=0.03 P=0.86
Female	29	108	137	
Age				
<5 years	25	58	83	X^2=6.88 P=0.03
5 <15 year	5	37	42	
>15 years	48	204	252	

Among the gram-negative isolates, *Escherichia coli* showed 100% sensitivity to colistin and tigecycline, 80% to ertapenem. *Acinetobacter* species showed 80% sensitivity to colistin and 70% to amikacin. *Enterobacter cloacae* showed 100% sensitivity to tigecycline,

Klebsiella pneumoniae showed 100% sensitivity to colistin and 88.3% to tigecycline. *Pseudomonas aeruginosa* showed 66.7% sensitivity to colistin (Table 3). Among gram positive isolates, CONS showed 93.1% sensitivity to linezolid, 89.7% to tigecycline and 86.2% to vancomycin. *Staphylococcus aureus* showed 100% sensitivity to oxacillin, gentamicin, linezolid, vancomycin, tetracycline and tigecycline. E*nterococcus faecalis* showed 100% sensitivity to gentamicin, linezolid and vancomycin (Table 4).

Very low positivity 1 (2.44%) was observed for *Spingomonas paucimobilis, Stenotrophomonas maltophilia, Burkholderia cepaciae* and *Serratia marcescenes.*

Tigecycline	10.3	0	100
Trimethoprim	51.7	66.6	50

DISCUSSION

The overall frequency of blood culture isolates in present study was (20.68%). This is comparable with studies conducted in India by Pal et al, 2016 (22.3%) and Gill et al, 2016 (24.8%).[5,4] However, some studies have reported high frequency of bacterial pathogens from blood cultures (24.2%-37.1%).[6,7] This may be due to use of different blood culture systems, different sample size, variations in study design and protocols, different geographical locations, variations in causative agents and the policies adopted for infection control between countries. Incidence of gram negative bacilli (GNB) was 52.56% and gram positive cocci (GPC) were 44.87%. Similar findings with high frequency of GNB as compared to GPC were previously reported by an Indian study.[8]

In our study, coagulase negative *staphylococcus* was the leading blood culture isolates (37.1%). Similar results were reported from India (61%) and globally (42%).[9,10] They often occur as skin contaminants during the collection of blood. Cross infections in ICU'S with multidrug resistant CONS can be prevented by use of appropriate antimicrobial agents. There is a need for differentiation between true pathogen and contaminant which can be achieved by correlating clinically the blood culture isolate and time taken for positivity of CONS.[11] Among the GPC group CONS showed high frequency of antimicrobial resistance as compared to others (Table 4). *Staphylococcus* aureus was 100% sensitivite to oxacillin, gentamicin, linezolid, vancomycin, tetracycline and tigecycline. Similarly, an earlier study reported 100% sensitivity to linezolid and vancomycin.[8]

Enterococcus faecalis was observed in (8.5%) of gram positive cocci. Similar findings (8.4%) were reported by an earlier Indian study.[11] It is a normal flora of female genitourinary tract and gastrointestinal tract. Though vancomycin resistance was reported since a decade, in the present study no resistance to vancomycin was observed for *Enterococcus faecalis*. This may be due to differences in the circulating strains. However, an earlier study from north India reported 23% of vancomycin rersistant enterococci.[11]

Gram negative bacteria accounted for more than fifty percent among the total isolates of the blood culture. This is consistent with an earlier study, though there is difference in the range of isolates.[1] Among the non fermenters, *Acinetobacter* species and *psuedomonas aeruginosa* showed high level resistance to cephalosporins and carbapenems. There is increase in the trend of carbapenem resistance to *Acinetobacter* species.[11] This may be because of extensive use of these antimicrobials. The overall antimicrobial resistance of gram negative bacteria and gram positive bacteria varied from 0% to 100% in our study. This is different when compared to a previous study which reported a higher resistance in gram negative bacteria (20-100%) as compared to gram positive bacteria (23.5%-58.8%).[12] Among the *Klebsiella pneumoniae* isolates high level sensitivity was shown by colistin 100% followed by tigecycline 88.3%, imipenem 64.7% and meropenem 41.2%. Singh et al, 2014 reported 100% and 71.4% sensitivity for imipenem and meropenem respectively each.[8] *Eschericia coli* showed high level sensitivity to colistin and tigecycline 100%, followed by ertapenem 80%, amikacin and gentamicin 70%. The sensitivity of gentamicin in our study was much higher as compared to an earlier Indian study 35%.[13]

Differences in antimicrobial resistant pattern in different studies may be due to circulation of different strains in different regions at different times.

Among the yeast isolates *Candida tropicalis* was isolated in two blood culture samples. Both the isolates were 100% sensitive to fluconozole, voriconazole, caspofungi, micafungin, amphotericin-B, and flucytosin. However, studies from different parts of India reported the emergence of *nonalbicans Candida* and resistant to widely used antifungal agents.[14,15]

CONCLUSION

Coagulase negative *staphylococcus* and *Klebsiella pneumoniae* were the predominant isolates of the study. High level multidrug resistance was observed in both GPC and GNB. Tigecycline and colistin remains the choice of antibiotics for gram-negative bacilli. Gentamicin, linezolid, vancomycin and tigecycline are the choice of antibiotics for gram positive cocci. Good antibiotic policy and strict hospital infection control measures may help to curb the emergence of multidrug resistant pathogens. There is a need for continuous monitoring and updating the BSI isolates and their antimicrobial patterns for an early effective approach to treatment.

ABSTRACT

Candida albicans remains the most frequently isolated species, but an increase in the prevalence of Non-albicans candida is a matter of concern for various laboratories, as NAC show less susceptibility to antifungal agents particularly azoles[1-3]. Routinely used conventional methods are cumbersome and time consuming. Hence the present study aimed at species identification of candida isolated from various clinical specimens and also to evaluate the usefulness of HiCrome Candida differential agar as compared to routine conventional method for speciation of candida. A total of 51 non repetitive clinical isolates of Candida were obtained from various clinical samples. *Candida albicans* was the major species accounting for 23 (45.10%) of the total isolates. *Non albicans Candida* constituted 17 (33.33%) of *C. tropicalis*, 9 (17.64%) of *C. krusei* and 2 (3.92%) of *C. parasilosis*. 49 Candida species which were correctly identified by HiCrome Candida agar except 2 species of C.parasilosis (identified by conventional method) which were identified as C. glabrata by Hicrome Candida agar.

KEYWORDS

Non-albicans Candida, HiCrome Candida differential agar, conventional method, candida speciation.

INTRODUCTION

Candida species particularly Candida albicans remains the most common cause of superficial and deep fungal infections worldwide[1,2]. But an increase in the prevalence of Non albicans Candida (NAC) during the last few decades is a matter of concern for various laboratories, as NAC show less susceptibility to commonly used antifungal agents particularly azoles ie fluconazole[3-5]. Thus species identification of Candida isolates have become very necessary for providing effective antifungal therapy, which will in turn prevent the emergence of drug resistance and also nosocomial infection[6].

A large variety of techniques from conventional to molecular methods are available for yeast identification[4,5]. Routinely used conventional methods like gram staining of smear, germ tube test, colony morphology on Sabouraud's dextrose agar, urease test, growth on corn meal agar, sugar fermentation and assimilation test, growth at 45^{0}C are labour intensive, cumbersome and time consuming ie may take 3-4 days[7].

Now a days, newer methods like several chromogenic media, BiGGYagar system, API system, Vitek 2ID system and molecular methods, have been developed for rapid identification of Candida species[8-10]. HiCrome Candida agar is one of the selective and differential chromogenic media manufactured by Himedia, Mumbia, India. This media contain chromogenic substrates that react with enzymes secreted by microorganisms producing colonies with various pigmentation. These enzymes are species specific, allowing organisms to be identified to the species level by their colour and colony characteristics[11]. They are used for rapid isolation and identification of candida species directly from clinical samples and also where multiple yeast species are present in the sample. On these media results are obtained in less time ie within 48hrs, can be easily interpreted and is also cost effective as compared to other newer methods like API system, Vitek 2ID system and molecular methods which are expensive[12-15].

As many tests from conventional to molecular methods are available, clinical microbiological laboratories are facing an important challenge regarding selection of method that is cost effective, accurate, easily interpreted and also rapid for identification of Candida, which inturn is of great importance for clinicians of our hospital to select appropriate prophylactic and therapeutic antifungal drug. Keeping the above point in view, the present study aimed at species identification of Candida isolated from various clinical specimens and also to evaluate the usefulness of HiCrome Candida differential agar as compared to routine conventional method for speciation of Candida.

MATERIALAND METHOD

Study design and setting – A prospective study was carried out in the department of Microbiology, NIMS Medical College and Hospital, Jaipur (Rajasthan) from January 2017 to May 2017. A total of 50 non repetitive clinical isolates of *Candida* obtained from various clinical samples, which were received from different Wards, ICUs and OPDs of the hospital and were submitted to microbiology laboratory with all aseptic precautions were included in the study.

Specimen processing [7]

1. Direct examination of sample- Direct microscopic examination by 10% KOH mount and Gram staining reveals presence of oval budding yeast cells with / without pseudohyphae[7].

2. Culture – All the clinical samples were inoculated on to Blood agar and SDA , both were incubated at 37C for 48-72 hrs. All the samples which showed growth were identified by colony characteristics and by gram staining. Once the conformation of colonies was done, they were further speciated[7].

3. Speciation of candida isolates (Fig 1-8)

(a) Standard conventional method - Candida isolates were further speciated by standard method which includes germ tube test, growth pattern on Corn Meal agar , sugar fermentation and assimilation test[7].

(b) Growth on chromogenic agar – Isolated Candida species were also inoculated on to the chromogenic media (HiCrome Candida differential agar (M1297A); Himedia, Mumbia, India.) Inoculated plate was incubated at 37^{0}C for 24 hours. These plates were further incubated for 48 hrs to get better well developed colored colonies. The color of the colony was interpretated as per color code provided on chromogenic media (Table 1) by two observer to avoid subjective variation[11]. All the isolates with doubtful morphology were considered unidentified and excluded from the study.

RESULT

In the present study, a total of 51 (4.5%) Candida species were isolated from 1113 clinical specimens. In our study conventional method was considered gold standard method for speciation. Out of 51 Candida isolates, most common isolated species was Non-albicans Candida ie 28 (55%) followed by Candida albicans ie 23 (45%) (Fig 4). Out of 28 Non-albicans Candida, C.tropicalis was most frequently isolated (33%) followed by C.krusei (18%), C.parasilosis (4%) (Fig 9).

These 51 strains were also identified using Hicrome Candida differential agar. 49 Candida species which were correctly identified by Hicrome Candida agar except 2 species of C.parasilosis (identified by conventional method) which were identified as C. glabrata by Hicrome Candida agar (Fig 10). 100% sensitivity and specificity was observed for Candida albicans, Candida tropicalis, Candida krusei. 0% sensitivity and100% specificity for Candida parasilosis (Table 2).

DISCUSSION

In the present study, out of 51 Candida isolates, 23(45.1%) were identified as C. albicans and 28 (54.9%) were NAC species. Our study showed that Non albicans Candida were isolated at higher rate (54.9%) than C. albicans (45.1%), which was in agreement with the studies conducted by Saroj Golia et al[17] and N.Pahwa et al[19] who also showed the Non albicans Candida incidence (64% and 58% respectively) to be higher than that of C. albicans . This change in pattern has been partly attributed to increased immune suppression resulting in higher number of susceptibility in immunocompromised patients and also due to the prophylactic use of antifungal agents in critically ill patients. Hospitalization (especially in ICU), placement of central venous catheters and the other indwelling devices, previous antimicrobial therapies have played significant role in this changing pattern of Candidiasis[22,23].

In our study, the most frequently isolated species was C. albicans in 45.1% of the infections, followed by C. tropicalis 33.3%, C. krusei 17.6% and C. glabrata 3.92% respectively. Hence C. tropicalis (33.3%) was the second most common species reported in the present study. This finding was comparable with other workers like L.Sumitra Devi et al.[18] (22.9%), Divya Dadhich et al.[20] (26.4%), and Khan and Bobade O, et al.[21] (21%) [table3].

In the present study, HiCrome agar showed 100% sensitivity and 100% specificity for C. albicans, C.tropicalis and C. krusei. Our study agrees with that of the studies conducted by D. Dadhich et al[20] and Nayak et al[24].,who also showed cent percent sensitivity and specificity to these Candida species when compared with conventional method.

In our study low sensitivity was reported for C. parasilosis which correlates well with the study conducted by tha of Baradkar et al[11].

These values are in contrast to the study conducted by various other scientists[24,25]. As both the species of C.parasilosis showed characteristic morphology on corn meal agar. Hence a combination of HiCrome and Corn meal agar can identify this Candida species with in 48 hours of culture.

CONCLUSION

On completion of this study it is concluded that *Non- albicans* Candida which was earlier considered to be non-pathogenic has emerged as important pathogen. It can no longer be discarded as a lab contaminant. Hence speciation of *Candida* species is of utmost importance in the present clinical scenario.

Speciation of *Candida* using conventional methods is quite cumbersome and time consuming. Therefore species level identification using HiCrome Candida agar medium is advocated. The advantages of HiCrome Candida agar is that it is easy to prepare i.e. boiling and dispensing in petri plates. It is technically simple and cost effective compared to technically demanding and time consuming conventional methods. It also facilitates identification of two or more different species present in a single clinical sample as is seen in our study. As a result it can be concluded that the use of HiCrome agar Candida is an easy reliable method for presumptive identification of most of the Candida species Furthermore, the species level identification of the Candida isolates along with their antifungal susceptibility patterns can greatly influence the treatment options for the clinician and may have an impact on the patient care.

Table 1: Colour of different Candida species on Hicrome agar

Species	Color of the colony
C. albicans	Light-green
C. dubliniensis	Dark-green
C. glabrata	Cream to white
C. krusei	Pink, fuzzy
C. parapsilosis	White to Cream
C. tropicalis	Blue to purple

Table 2: Sensitivity and specificity of HiChrom agar for identification of various Candida spp.

Candida spp	No.of Candida spp. identified by conventional method	No.of Candida spp. identified using HiCrome agar	Sensitivity of HiCrome agar	Specificity of HiCrome agar
C. albicans	23	23	100%	100%
C. tropicalis	17	17	100%	100%
C. krusei	9	9	100%	100%
C. parasilosis	2	0	0	100%

Table- 3 Candida species isolated in various studies

Abstract: *With the increasing incidence of Methicillin Resistant Staphylococcus Aureus(MRSA), Vancomycin Intermediate Staphylococcus Aureus(VISA) & Vancomycin Resistant Staphylococcus Aureus (VRSA) strains now a days. The study was conducted to find out the magnitude of vancomycin resistance in both MRSA and MSSA and antibiotic susceptibility pattern of those isolates in a tertiary care hospital, Jaipur between January 2017 to June 2018.In this cross sectional study,287 Staphylococcus aureus were isolated and identified from various clinical specimens collected from different departments of the hospital.Among these 287 strains,146 were found to be MRSA and 141 MSSA. Subsequently ,the antimicrobial susceptibility test was performed by Kirby Bauer disc diffusion method as per CLSI guidelines. All strains found resistant to vancomycin by disc diffusion method were again grown on BHI-VSA(Brain heart infusion-Vancomycin screen agar) and also recruited to E- Test for confirmation of resistance. Minimum Inhibitory Concentration (MIC) of ≤2 were considered as VSSA,4-8 as VISA.MIC of ≥16 as VRSA. Vancomycin resistance was seen in 9 isolates of S. aureus by disc diffusion method. Among them neither was found to be VISA nor VRSA when confirmed with E-Test with all having MIC <2 .Though there was no incidence of VRSA but MIC of 1.5µg/ml in our study rang an alarm to the infection control committee of this tertiary care hospital.*

Keywords: *MIC, S.aureus, VISA, VRSA, Vancomycin Screen Agar*

I. Introduction

Staphylococcus aureus is one of the most notorious and important human pathogen that has long been recognized for its ability to cause serious and invasive diseases. Staphylococcus aureus is the most pathogenic member of Staphylococcus genus. This microbe is ubiquitous in nature which resides in the human as a commensally. Some of the commoner infection caused by Staph. aureus include Pyogenic infection (eg. Folliculitis impetigo, breast abscess, post operative wound infection, osteomylitis, septic arthritis, bronchopneumonia, lungs abscess, empyema). Disseminated infection such as Septicemia. Toxic shock syndrome (TSS), staphylococcal scalded skin syndrome(SSSS), staphylococcal food poisoning.[1] A wide range of antibiotics are used to treat the staphylococcal infections including penicillin, cephalosporin, macrolide, fluroquinolone and glycopeptide group of antibiotics.[3] In early 90s,the major treatment available to combat this organism was Penicillin and all isolates were sensitive to penicillin. In the 1960s, a new semisynthetic penicillinase-resistant antimicrobial drugs *methicillin* (formerly named as celbenine) and oxacillin were developed to treat staphylococcal infections caused by β-lactamase-production.[4] But at present, some S. aureus strains also show resistant to methicillin.[2]

Methicillin-resistant Staphylococcus aureus (MRSA)[5] has been recognized as one of the major pathogens in both hospital and community settings. The first case of MRSA was isolated way back in 1961.Since then, there has been an escalating rate of infections caused by MRSA worldwide resulting in increased mortality and morbidity statistics. In India, the prevalence of nosocomial infections caused by MRSA varies between 20 and 40%.*Vancomycin***,** a glycopeptides antibiotics had been considered to be the "gold standard antibiotic" and the drug of choice over the last 3 decades[6]

Apart from vancomycin ,other effective drugs as linezolid and teticolanin are also widely used. Injudicious and infrequent use of vancomycin even in methicillin sensitive Staphylococcal infection has resulted in emergence of the strains with higher vancomycin MIC.[7] At present few vancomycin resistant S.*aureus* strains have been reported. Initially in early twenties,only VISA (Vancomycin intermediate S. *aureus*) strains

were reported by CDC but even now in India, there is emergence of S.aureus strain with higher vancomycin MIC.

This higher vancomycin MIC has been attributed by increased thickness of cell wall as in case of Vancomycin Intermediate Staphylococcus aureus.[8] Vancomycin resistance is acquired by mutation and thickening of cell wall due to accumulation of excess amounts of peptidoglycan.[9]

Keeping the above points in view and also that documented reports of VISA and VRSA in India including Rajasthan are very few ,the present study was planned to find out the prevalence of vancomycin intermediate Staphylococcus aureus and vancomycin resistant staphylococcus aureus among isolates of Staphylococcus aureus in various clinical specimens along with their antibiotic sensitivity pattern so as to guide the clinicians of our hospital to select appropriate antimicrobial agents and also to make them aware ,that if inappropriate use of vancomycin is continued it may lead to impending public health disaster. There fore the present study is designed to find out the prevalence of vancomycin intermediate and resistant Staphylococcus aureus in clinical specimen and to determine the antibiotic susceptibility pattern of vancomycin intermediate and resistant Staphylococcus aureus and to measure the MIC values of vancomycin intermediate and resistant Staphylococcus aureus by E-test.

II. Material And Methods

The present study was conducted in the Department of Microbiology, NIMS Jaipur during the year 2017-2018. A total of 287 non- duplicate Staphylococcus. aureus isolates from various clinical specimens [pus, wound or vaginal swabs, blood, body fluids (csf, pleural fluid, ascitic fluid) urine, sputum, ET secretion etc. were included in the study. Isolates from both in-patients and out-patients were considered. Institutional Ethical clearance was obtained. Data regarding age, sex, etc was obtained from the requisition form submitted to microbiology Department, NIMS, Jaipur.

2.1 Isolation & Identification, of Staphylococcus aureus[10,11]

Smears were prepared from pus, wound swab, sediments of body fluids and respiratory samples, stained by Gram staining and examined for presence of inflammatory cells, epithelial cells and the type of microbial flora. As soon the samples received in the laboratory, Streak culture method was employed for sample inoculation on Blood agar, Nutrient agar. Culture plates were incubated at 37^{o} C aerobically for 24-48 hours .Plates were observed for typical colony characteristics of Staphylococcus aureus on Blood agar (β haemolysis) and Nutrient agar (yellow pigment).For plates with mixed culture growth, sub culture was done on blood agar and incubated for 18-24 hours aerobically at 37^{o}C. Sub culture was also done for Staphylococci colonies more than 48 hours old, where ever required. Gram's staining was performed from representative colonies, and observed for Gram positive cocci in clusters, under oil immersion microscope. Catalase test was performed from Nutrient agar plate. This test is positive for Staphylococcus aureus and differentiates from Streptococci. Slide coagulase test was employed to detect presence of clumping. factor (bound coagulase) which was indicated by prompt clumping in positive isolates. Irrespective of result of slide coagulase test, tube coagulase test was done for presence of coagulase enzyme (Free coagulase). Staphylococcus aureus is positive. For all Staphylococcus aureus strains mannitol fermentation was observed on Mannitol salt agar.

2.2 Antibiotic Sensitivity testing of Staphylococcus aureus[12]

Antibiotic susceptibility to a panel of drugs was tested using (Modified Kirby Bauer's method. Antibiotic discs procured commercially [Hi-media Laboratories, Mumbai] and were placed on inoculated MHA plates using forceps. Plates were incubated at 35±2PC for 18-24 hours. Zone of inhibition of all the antibiotics were measured with scale in reflected light against a black background, to the nearest mm. Interpretation was done according to the guidelines of Clinical Laboratory Standards Institute (2012). All Staphylococcus aureus isolates were subjected to predetermined panel of antibiotics which includes cefoxitin[30ug], Penicillin [10µgm], Cotrimoxazole [1.5/23.75µgm], Erythromycin[15µgm], Ciprofloxacin [5µgm], Clindamycin [2 µgm], Gentamycin [10 µgm], Levofloxacin [5 µgm], Tetracycline [30 µgm], Vancomycin [30 µgm]. Staphylococcus aureus ATCC 25923 was used as control. Cefoxitin disc (30 µgm) was used along with other antibiotics, to detect methicillin resistant isolates as it is a potent inducer of mec A gene mediated resistance[12].

2.3 Detection of Vancomycin resistance

Following 3 methods were used and comparison between modified Kirby -Bauer disc diffusion method using 30μg Vancomycin disc and BHI vancomycin screen agar (6 µg/ml) was done keeping in view E-test as gold standard for detection of vancomycin resistance.

2.3.1 Disc diffusion by Modified Kirby Bauer's Method[13]

It was performed using Vancomycin 30p.g disc. The diameter of-zone of inhibition was measured and interpreted according to CLSI guidelines 2007 [13]. B.BHI vancomycin screen agar[12] BHI-VSA (Hi-Media, India) plates containing 6m/m1 vancomycin were prepared. Inoculum suspensions were prepared by selecting colonies from subcultured colonies on nutrient agar plates. The colonies were transferred to sterile saline to produce a suspension that matches the turbidity of a 0.5 McFarland standard. Using a micropipette, spot of 10-µL drop onto agar surface was done and were incubated aerobically at 35±2°Cfor 24 hrs[14]. Any growth is examined carefully with transmitted light.

2.3.2 Determination of Minimum Inhibitory Concentration (MIC) values[15]

The MIC value of vancomycin was determined by E-test [Epsilometer-test]. Inoculum suspensions were prepared by selecting colonies from overnight growth on nutrient agar plates. The colonies were transferred to sterile saline to produce a suspension that matches the turbidity of a 0.5 McFarland standard and a lawn culture was prepared by pouring the growth suspension on the surface of the BHI agar plate. After drying the surface for half an hour, the E-strips were placed over the surface and incubated over night at 35°C.The plates were read only when sufficient growth was seen and the MIC values were recorded where the ellipse intersects the MIC scale on the strip. If the ellipse intersects the strip in between 2 dilutions MIC was recorded as the value which is nearest to the intersection. For classifying isolates of Staphylococcus aureus with reduced susceptibility to vancomycin based on the laboratory breakpoint published by the clinical and laboratory standards institute [CLSI guidelines][12]

Vancomycin sensitive Staphylococcus aureus [VSSA]: ≤2 µg/ml.
Vancomycin intermediate Staphylococcus aureus [VISA]: 4-8 µg/ml.
Vancomycin resistant Staphylococcus aureus [VRSA]: ≥16 µg/ml.

III. Observation And Results

During the study period, a total of 287 non duplicate Staphylococcus aureus isolates were obtained from variation clinical specimens. Methicillin resistance was detected in 146 (51%) of the total isolates. Isolates that were sensitive to methicillin were 141 (49%) in 287strains.

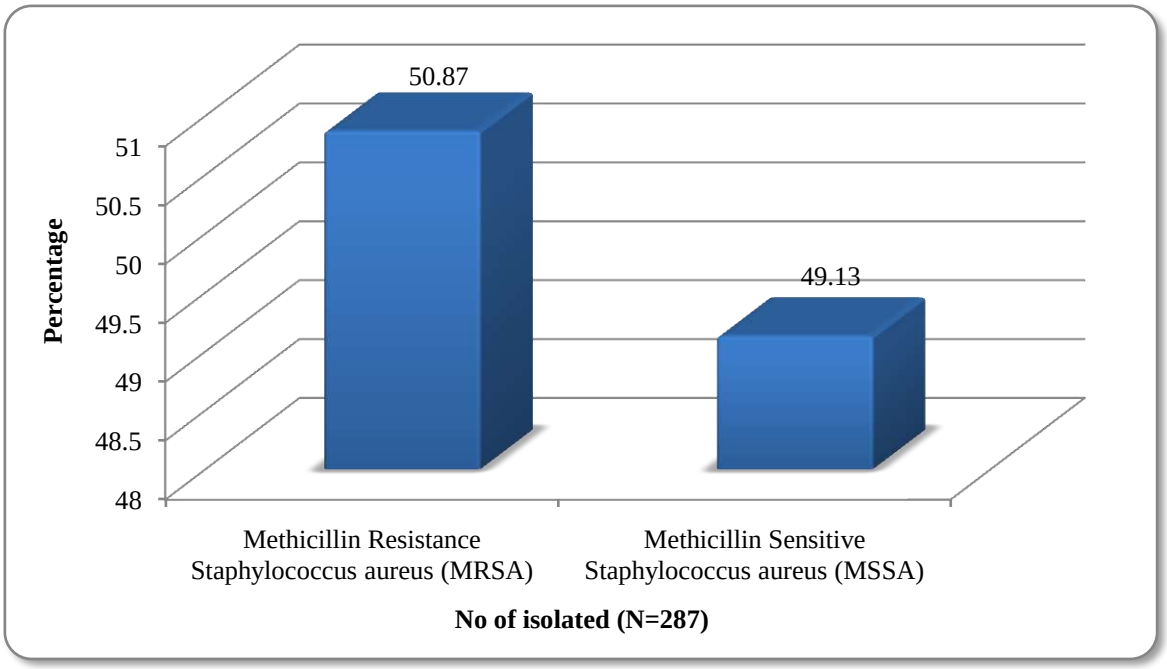

Fig. 1: Prevalence of MRSA and MSSA in total of 287 Staphylococcus aureus isolates

3.1 Vancomycin Resistance

Three phenotypic methods employed in detection of Vancomycin resistance,

3.1.1 Disc Diffusion method

In a total of 287 S.aureus stains, 9 (3%) isolates had shown resistance towards Vancomycin in Disc diffusion.

3.1.2 BHI Vancomycin screen agar (6 ugtn/ ml)

None of the isolates grew on So no resistance is.reported by this method.

3.1.3 Epsilometer [E-testl for Vancomycin

It was considered as Gold Standard. MIC values of all the 287 isolates fall in between range of≤ 2µg /ml, which is category of sensitive. All of the 9 isolates, which were resistant by Vancomycin disc diffusion, are in range of sensitive MIC.

Table No 1: Detection of Vancomycin resistance by different phenotypic methods

Methods	VISA	VRSA	VSSA	Total
Vancomycin disc diffusion (30 ug/disc)	NA	9	278	287
Vancomycin Screen Agar(6ug/ml)	00	00	287	287
Vancomycin E Test	00	00	287	287

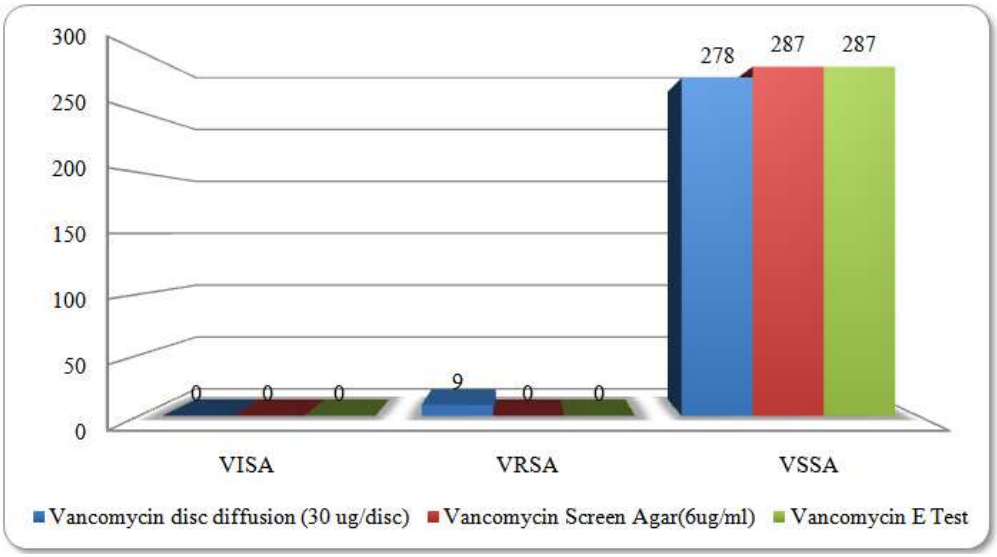

Fig. 2: Detection of Vancomycin resistance by different phenotypic methods

Table No 2: Distribution of the cases according to MIC Values (ugm/ml) against vancomycin

MIC Values (ugm/ml)	Total	
	No	%
0-0.5	169	58.89
>0.5-1	112	39.02
>1-1.5	6	2.09
Total	287	100.00

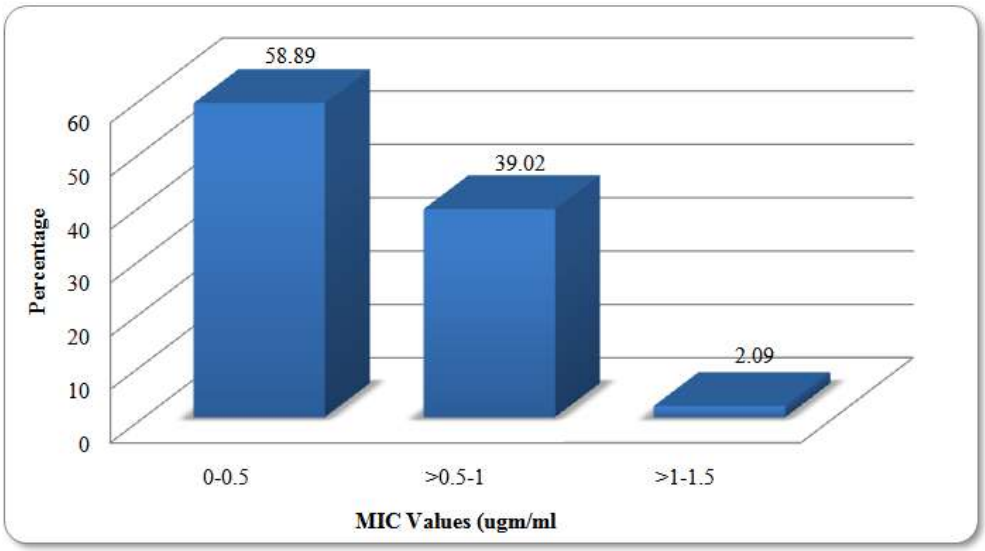

Fig.3: Distribution of the cases according to MIC Values (ugm/ml) against vancomycin

3.2 Antibiogram

All 287 Staphylococcus aureus strains were tested for antibiotic susceptibility pattern against a panel of predefined antibiotics, which was described earlier.

Staphylococcus aureus showed 88% resistance to Pencillin G, followed by 51% resistance to Cefoxitin, 43% each to Co-trimaxazole and Erythromycin, 66% to Ciprofloxacin, 31% to Clindamycin, 16% to Gentarnycin and 28% to Levofloxacin and 3% each for both Tetracycline and Vancomycin.

IV. Discussion

Staphylococcus aureus is a major human pathogen and is one of the commonest causative agent of Community and Hospital acquired infections[11]. The treatment of Staphylococcus aureus infection has become problematic because of emergence of resistance to Penicillin, Methicillin, Vancomycin and many other antibiotics, by acquiring several resistance mechanisms. Increased antimicrobial resistance for such an organism is, therefore a cause of concern.

In the past few decades MRSA has emerged as an important nosocomial pathogen worldwide. In India, prevalence rate varies from 30-85% in different parts and has now become endemic.[16,17,18] A multicentric study done in India involving 17 tertiary care Hospitals reported MRSA prevalence of 41% in 2008-2009.

MRSA is of serious therapeutic, concern not only due to its resistance to Methicillin, but also because of resistance to many other antimicrobials that are used on regular basis in Hospitals. Therefore, the most reliable and sustained therapeutic agerit against methicillin-resiStant Staphylococcus aureus (MRSA) strains is Vancomycin[19]. There is still controversy in clinicians regarding the outcome of Vancomycin treatment in MRSA. Increasing prevalence of MRSA, lead to the extensive use of vancomycin. This inturn lead to the decreased susceptibility to Vancomycin all over the World including India, this was soon followed by strains of Staphylococcus aureus that were totally resistant to vancomycin[20,21]. Such resistance resulted in serious clinical and public health consequences because currently few licenced alternatives are available. to treat vancomycin resistant Staphylococcus aureus infections.

Thus the present study was undertaken to determine the current status of Vancomycin susceptibility in our Hospital setup. to compare the Vancomycin disc diffusion test with BHI- VSA [6µgm/ml] for detecting Vanomycin resistance considering E-Test as gold standard and also to determine the antibiotic susceptibility pattern of these isolates.

In the present study a total of 287 non-duplicate staphylococcus strains were isolated from various clinical specimens. Among all these samples highest isolation was from pus 175 (61%). Harcharan Singh et al in Udaipur (65%)[22], Manu Chaudhary et al in H.P (63%)[23] and Ankur Goyal et at in Agra (66,03%) [24], also reported the highest isolation of Staphylococcus. aureus from pus.

In our study 146 (51%) isolates turned out to be MRSA and 141 (49%) as MSSA. from a total of 287 Staphylococcus aureus strains. The prevalence rate of MRSA in our institute is 51%, which is similar to the studies conducted by S.Vidhani and P.L. Mehndiratta et al in 2001[25] showing a prevalence rate of 51.6% and almost comparable -to the study conducted by Majumdar et al in 2001[26] and Assadullah et al in 2003[27] showing 52.9% prevalence rate. The higher rate in their studies may been attributed to the fact that the studies were conducted at a tertiary care multispecialty center with more and more patients coming from periphery and small nursing homes, where injudious use of antibiotics and inadequate infection control policies are prevalent.

In the present study, maximum MRSA were isolated from pus 89(61%), followed by blood 22(15%), respiratory secretions 15(10%), Swabs and body fluids 7(5%) each and least from Urine 6 (4%). This pattern correlates with studies conducted by Vidya Pai et al in 2010[28] and Nitish Kumar Sharma et al 2013[18]. This is due to the reason that Staphylococcus aureus accounts for most of the skin and soft tissue infections, septicemia and also respiratory tract infection.

Comparatively MRSA prevalence was more in males. (71%) than in females (29%) in our study: Similar findings was also reported by Rao BN et al[29] and Abhishek Mewar et al[30]. The increased rate of MRSA infections among males could be due to their more outdoor activities, inturn exposing them to contaminated environment and also compared to females, accidental injuries are more common among men.

Most of the MRSA strains were isolated from 21-30 yrs of age group (ie 23.69%) and in 31-40yrs (ie 17.77%), indicating MRSA infection is more common in working and old age group. The reason for this may be that younger age group are more involved in outdoor activities inturn exposing them to contaminated environment and in older age group it may be due to waning immunity, hormonal abnormalities and co-morbid conditions. Similar pattern of affected age group. was also reported by Ankur Goyal et al in 2013[24].

In the present study all 287 Staphylococcus aureus strains were screened for vancomycin resistance by Vancomycin disc diffusion method [30g/disc] and BHI-Vancomycin screen agar [6µg/ml]. These were further confirmed by Vancomycin E-test. All 287 Staphylococcus aureus isolates had MIC values ≤ 2µg/ml, hence all were sensitive to Vancomycin and were labeled as VSSA according to the CLSI guidelines 2012[12]. Among

these 169(59%) isolates had MIC of < 0.5µg/ml, 112[39%] had MIC of >0.5-1 µg /ml. Only 6[2%] had MIC of >1-1.5 µg /m1 and none of the isolates had MIC values of >1.5 µg /ml.

In our study no VISA. and VRSA found. This may be due to the fact that the community acquired MRSA (CA-MRSA) unlike the hospital acquired MRSA (HA-MRSA) are known to be sensitive to drugs other than vancomycin. Because of its. high cost, vancomycin may not be in use in the peripheral rural setups, thus decreasing the selection pressure for vancomycin resistance[31].

The current study only indicates the tip of iceberg. More and more studies should be undertaken in future to 'monitor the emergence of resistance to these. antibiotics. This also necessitates to find out better treatment policies and also to use cheaper and effective alternative anti - MRSA drugs so as to reduce the antibiotic pressure on vancomycin. Also clinicians should continue to exercise caution in their use of vancomycin in order to preserve this useful antibiotic and prolong its therapeutic usefulness.

V. Conclusion

To conclude, the result of our present study indicated high antibiotic resistance in commonly used antibiotics by MRSA isolates. The increased use of vancomycin drug has worsened the sensitivity.

We should undertake more and more such studies in future to fight against rising menace of antibiotic resistance, Also more research should be done to find better treatment policies, effective and cheaper alternative antibiotics in developing countries like ours. Even the clinical microbiology laboratories must ensure using detection methods with good sensitivity and specificity. We should also undertake more studies to find out the accurate screening method for VISA and VRSA. The findings of the studies should be shared with hospital infection control committee to help in the formulation of infection control polices and also antibiotic policies. So that the primary care givers can use antibiotics rationally.

However, S. aureus with reduced susceptibility was not observed in the present study. So, as a precautionary measure before starting the patient on vancomycin, the clinicians should seek the help of Clinical Microbiologist to determine the MIC of such strains so that emergence of vancomycin resistance can be prevented. All the laboratories should routinely test the MIC of vancomycin for all Staphylococcus aureus infection for appropriate treatment of patients and also for implementation of infection control.

Abstract

The changing epidemiology from *Candida albicans* to *Non-albicans Candida* along with increasing antifungal resistance is a matter of great concern in health care settings. The studies on *Candida* have largely been carried out by the morphological identification but to the best of my knowledge very little work has been done in Rajasthan to find out antifungal susceptibility pattern of *Candida* species. Keeping in view the above facts, this study was undertaken for identification and evaluation of antifungal susceptibility pattern of *Candida* species isolated from various clinical samples in a tertiary care hospital, Jaipur. A total of 51 candida species were isolated during a period from Jan 2017- May 2017 and identified by standard microbiological procedures. Antifungal susceptibility testing was carried out on the basis of CLSI M44-A guidelines. Out of 51 Candida isolates, 23 were candida albicans and 28 were Non-albicans candida. Among Non – Candida albicans, 17 isolates were C.tropicalis, 9 and 2 isolates were C. krusei and C. glabrata respectively. Candidiasis was more commonly found in female patients and in 20-39 years of age group. Overall, antifungal susceptibility of Candida species to Fluconazole was 57%, Voriconazole 76%, 88% to Amphotericin B and 94 % to Nystatin. Therefore, The changing trends in epidemiology of candidiasis, necessitates the speciation of candida species which inturn facilitate the development of effective measures to prevent and control transmission of resistant pathogen.

Keywords
Changing trends, candida species, candidiasis, antifungal susceptibility.

INTRODUCTION

The incidence and prevalence of fungal infection due to Candida species are increasing significantly in the recent few decades, so contributing to morbidity and mortality[1]. This increase is mainly due to expanding population of immunocompromised patients that use total parenteral nutrition and intravenous catheters; increasing use of prolonged antibiotic therapy; in organ transplant recipients and also a rise in use of invasive procedures for diagnosis and treatment[2,3].

Candida spp, belonging to yeast like fungi are the normal commensal microflora of skin, mucous membrane of oral cavity, gastrointestinal, genitourinary and respiratory tract[4]. They become pathogenic particularly when the host defense mechanism is lowered and causes an opportunistic infection[5,6].

Genus Candida includes > 500 species, in which only 20 species are recovered from human samples[7]. Among these 20 Candida species, *Candida albicans* is generally considered as major pathogen. But recently published epidemiological data highlights an increase of Non-albicans candida species such as *C. tropicalis, C. parapsilosis, C. glabrata, C. dubliniensis and C. krusei*[8].

In addition, the numbers of new Candida species isolated from clinical samples are increasing continuously every year, which were previously considered "non-pathogenic". The major reason for this could be the use of various commercially available identification methods by clinical microbiology laboratories worldwide to supplement the conventional methods of identification, also a rapid increase in number of immunocompromised patients worldwide in view of the HIV epidemic, organ transplantation and malignancies[9].

Candidiasis is the commonest fungal disease, usually endogenous in origin. All Candida species causes diseases ranging from simple mucosal colonization, superficial infections such as oral thrush to invasive fungal diseases, yet they show difference in disease severity and susceptibility to different antifungal agents[10].

Fluconazole is a triazole most effective and frequently prescribed antifungal drug for treatment of candidiasis, as it has an excellent patient tolerance and minimal side effects. A growing worldwide increase in use of this drug for treatment of candidiasis, in turn lead to drug resistance and also one of the principal causes of recent increase in prevalence of non- candida albicans candidiasis[11].

The changing trends of candidiasis necessitates the speciation of candida species which inturn facilitate the development of effective measures to prevent and control transmission of resistant pathogen. Hence the present study was carried out to detect the clinical distribution of candida species in various clinical specimens along with their antifungal susceptibility pattern.

MATERIAL AND METHOD:

Source of material - The present study was conducted in the department of Microbiology, NIMS Medical College and Hospital, Jaipur (Rajasthan) from January 2017 to May 2017.

Inclusion criteria

- All the *Candida* species isolated from various clinical samples will be included in the study.

Exclusion criteria

- All other fungal isolates except *Candida* species were excluded from the study.

Processing of Samples

During this period all clinical samples suspected of fungal infection, which were received from different Wards, ICUs and OPDs of the hospital and were submitted to microbiology laboratory with all aseptic precautions and processed in the following manner -

1. Direct examination of sample[7]- Direct microscopic examination by 10% KOH mount and Gram staining reveals presence of oval budding yeast cells with / without pseudohyphae.

2. Isolation and Identification of Candida species[7] - This was done by standard conventional method ie inoculation of the sample on to Blood agar and SDA, both were incubated at 37°C for 48-72 hrs. All the samples which showed growth were identified by colony characteristics and by gram staining. Once the conformation of colonies was done, they were further speciated by germ tube test, chlamydospore formation on Corn Meal agar, sugar fermentation and assimilation test.

3. **Antifungal susceptibility pattern[12,13]**- This was done by agar disc diffusion method as recommended by CLSI (M-44A) guidelines. Mueller - Hinton agar with 2% glucose and 0.5ug/ml methylene blue and antifungal agents like Fluconazole, Voriconazole, Nystatin and Amphotericin B were used.

RESULT:

In the present study, a total of 51 (4.5%) Candida species were isolated from 1113 clinical specimens (Fig-1). Maximum Candida were isolated from patients in the age group of 20-39 yrs (33.3%) followed by extremes of age ie 60-79 yrs (23%) and <19 yrs (22%) (Fig-2). Candidiasis was more common in female patients ie 28 (55%) than in males' patients ie 23(45%). Female: Male ratio was 1.2:1 (fig 3).

Out of 51 Candida isolates, most common isolated species was non - Candida albicans ie 28 (55%) followed by Candida albicans ie 23 (45%) (Fig 4). Out of 28 Non-albicans candida, C.tropicalis was most frequently isolated (33%) followed by C.krusei (18%) and C.glabrata (4%) .

Majority of Candida species were isolated from urine samples (51%) followed by sputum (22%), HVS (10%), ear swab (8%), 2% each from foleys catheter, blood, stool, ET secretion and throat swab (Fig 5). Among the isolates derived from urine, C.tropicalis (42%) was predominant followed by C.albicans (27%) and C.krusei (23%), where as C.albicans(82%) was most frequently isolated from sputum sample followed by C.krusei (18%) (Fig 6).

Overall, antifungal susceptibility of Candida species to Fluconazole was 57%, Voriconazole - 76%, 88% to Amphotericin B and 94 % to Nystatin. Hence among the 4 antifungal drugs highest susceptibility was observed for Nystatin and highest level of resistance to Fluconazole 43%. Candida albicans was 100% sensitive to Nystatin and Amphotericin B, 87% and 78 % sensitive to Fluconazole and Voriconazole respectively, where as C.tropicalis was 88%, 82%, 65% and 59% sensitive to Nystatin, Amphotericin B, Voriconazole and Fluconazole. 100 % resistance was seen in C. glabrata against Fluconazole, followed by 100% sensitivity to Nystatin and Voriconazole. In case of C.krusei, 89% resistance was reported for fluconazole, followed by 11%, 22% and 33% resistance to Nystatin, Amphotericin B and voriconazole respectively. (graph 1,2,3,4).

DISCUSSION:

Over the past two decades, a significant increase in the incidence of mycosis in general and Candidiasis in particular is reported in various studies[14]. Also, in recent years non- Candida albicans, emerged as a major pathogen causing serious diseases in humans as they are resistant to commonly used antifungal agents[15]. To tackle this grave situation, the present study was under taken to provide a detailed analysis of the distribution and antifungal susceptibility of 51 isolates of Candida species in various clinical samples and in patients of different age group and gender.

In the present study maximum number of Candida species were isolated from urine samples followed by sputum samples. This is similar to the study conducted by Sukumaran et. al.[16] and Agarwal et. al.[17], in which more no of Candida isolates were found in urine samples. Similarly, a study conducted by Sundar Khadka et. al.[18] isolated maximum number of Candida species from urine (48%) and sputum (42%) samples. These studies indicate increased incidence and isolation of Candida species in Urinary tract and respiratory tract infection.

In the present study Non-albicans candida were isolated at a higher rate (55%) than C.albicans (45%),which was in agreement with the studies conducted by Ragini et al.[19],Chakrabarthi et al.[9] and Agarwal et al.[21] These studies indicate that Non-albicans candida are emerging as a major pathogen and they are treat for future. This change in pattern has been partly attributed to increased immune suppression resulting in higher number of susceptibilities in immunocompromised patients and also to the prophylactic use of antifungal agents in critically ill patients. Hospitalization (especially in

ICU), placement of central venous catheters and the other indwelling devices, previous antimicrobial therapies have played significant role in this changing pattern of Candidiasis.

Among the non- Candida albicans, C.tropicalis(33%) was most frequently isolated followed by C.krusei(18%) and C.glabrata(4%).These findings are comparable to the studies conducted by different researchers like Divya Dadhich et al.[22] and L. Sumitra deviet al.[23] while a study carried out by Mokadas et al.[24] reported C.parasilosis as the most common Non-albicans candida species. In our study the most common isolate in Urine and blood samples was C. tropicalis which correlates well with the study of L. Sumitra Devi et al.[23] C. albicans was the most common isolate in Sputum which is in accordance with the studies of B. Madhumati et al.[25]

In the present study, it was found that Candidiasis can occur at all ages. The youngest in our study was one-year old baby while the eldest was 85 years. The mean age was found to be 43 years. The highest incidence was seen in the age group of 20-39 years. This is similar to the study conducted by Lata R Patel et al, Dalal et al.[100], Jayalaxmi et al[101] showing maximum cases in the age group of 21-40 years.

Comparatively Candida isolation was more in female patients (55%) than in male patients (45%) in our study. Similar finding was also reported by Megha Pawar et al and Sujatha R et al with female predominance. The possible reason is that Candiduria and genital Candidiasis is more common in females during reproductive age group.

In this study, Candida species were more susceptible to Nystatin, followed by Amphotericin B (88%), Voriconazole (76%) and Fluconazole (57%). Hence Nystatin and Amphotericin B emerged as most efficacious drug for the treatment of Candidiasis and also 43% Candida isolates demonstrated resistance to fluconazole which is similar to study done by Deorukhkar et al. Highest resistance to fluconazole was reported by Non – Candida albicans.

CONCLUSION:

To conclude, the present study highlights the predominance of Non- Candida albicans in various clinical specimens. Among commonly used antifungal drugs Nystatin, Amphotericin B, Voriconazole showed high rates of sensitivities while Fluconazole was least effective for candidiasis. This study in our set up will help in recognizing the emerging candida species along with their increasing drug resistance. Therefore, the changing trends of candidiasis, necessitates the speciation of candida species along with their antifungal susceptibility pattern, this will enable the clinicians to choose appropriate antifungal agents, which will inturn decrease the patient's morbidity and mortality.

Blood stream infections are very common in the paediatric age group and these are one of the common causes of morbidity and mortality in neonates and children. Objectives of the study are to isolate the different organisms from Blood cultures of Neonates by BACTEC method and know their Antibiotic susceptibility patterns. We processed 100 Blood samples of the Neonates from PICU of NIMS Medical College and Hospital between January and June 2016 (06 months). Samples were collected in BACTEC PEDS PLUS vials with all aseptic precautions. The vials were placed in the BACTEC 9050 and cultured. The positive vials were further plated on BA, MacConkey Agar looked for the growth and identified by necessary biochemical reactions and antibiotic susceptibility is done by Kirby-Bauer method. Out of 100 blood culture samples, 58 were positive. Out of 58, 18 yielded CoNS (31.03%), 12- *Klebsiella* spp (20.68%), 04 - *Staphylococcus aureus* (6.89%), 06 - *Enterococcus* spp (10.34%), 12- *Enterobacter* spp (20.68%), and 02 each of *E. coli* (3.44%), *Citrobacter* (3.44%) and *Acinetobacter* (3.44%). Significantly high rates of Gram Negative bacterial infections were seen followed by Gram Positives. Automated Blood Culture systems significantly reduced the time required for processing of samples and also facilitated the yield of diverse organisms. Antibiotic Susceptibility patterns also showed Gram Negative bacteria to be less sensitive than Gram Positive bacteria.

Introduction

Blood stream infections are very common in the paediatric age group and these are one of the common causes of morbidity and mortality in neonates and children. The incidence of sepsis is increasing all over the world leading to high morbidity and mortality rates (Kavitha *et al*., 2010). Detection of Bacteremia by blood culture is critical in managing patients with infection, and directs the appropriate selection of antimicrobials. Blood culture is a common laboratory investigation where blood is inoculated into culture medium and continuously monitored for positive growth. Media used in the blood culture bottles support the growth of most medically important bacteria. Manual culture techniques often take a longer duration for detection and isolation of organisms (Tarai *et*

al., 2012). Blood culture technology has changed from tube or bottles of liquid culture medium requiring frequent inspection, microscopic or blind plating on to solid culture medium to see if growth has occurred to modern, closed, computer based systems, which assess changes in CO2 indicating growth every 10-15 minutes (the BacT/ALERT microbial detection system, Organon Teknika Corporation, Durham, North Carolina, USA) (Butterly, 2002). The BacT/ ALERT method is reported to more rapidly detect positive blood culture results in pediatric and newborn patients than other systems (Kumer *et al.*, 2001).

Sepsis is a commonly encountered and potentially life threatening problem in Neonatal intensive care units (NICU's), it is not easy to establish a definite diagnosis of Sepsis in the neonates. Early clinical signs are mostly non-specific and in conclusive (Khadija *et al*., 2011). Current study was undertaken to find out the common bacterial pathogens and their susceptibility pattern in neonates with sepsis in a tertiary care hospital providing neonatal intensive care services. Improvement in outcome and successful treatment depends on early initiation of appropriate antibiotic therapy (Srinivasa *et al*., 2014). It is estimated that 26% of newborn infants who die do so as a result of infections that occur around birth. After the first week of life, infections are the main cause of neonatal death in many countries. Most published data are from hospitals where *Klebsiella* species, *Escherichia coli* (*E. coli*), and *Staphylococcus aureus* (*S. aureus*) are the most common causes of infection (Shrestha *et al*., 2013). The early symptoms of sepsis are non-specific, and the outlook is considered to be worst in babies in whom antibiotics are started late. Antibiotics are therefore generally given to all babies with clinical or laboratory indicators of infection and babies at high risk of early onset sepsis. A large number of babies who are evaluated for sepsis do not have proven infection. This means that most of the antibiotics given to babies on the neonatal unit are given to babies without infection. Inappropriate use of antibiotics has been implicated in the development of multi-resistant bacteria in hospitals, Recently published studies suggest that antibiotic courses may be safely reduced to 24–36 hours in asymptomatic term babies (Kumar *et al*., 2001; Khadija *et al*., 2011).

Thus the Objective of this study was to measure the time required for the bacteria to be detected in blood cultures taken from suspected sepsis newborns by the BACTEC microbial detection system (Waricha *et al*., 2006) and also to establish an anti-biogram pattern in and around NIMS University, Jaipur.

Materials and Methods

NIMS Medical College and Research Centre is a 950 bedded hospital located in Jaipur. There is a dedicated team of 05 doctors at Central Laboratory handling approximately 600-650(includes pathology, microbiology and biochemistry samples) samples per day. Microbiology lab is equipped with BACTEC 9050 Blood Culture System (BD).

In this study we used BACTEC PEDS PLUS vials (Yellow top- paediatric aerobic) from the neonates suspected of Septicaemia from PICU. We analyzed 100 blood cultures collected during January to June 2016 after approval of the Hospital ethical committee.

Blood Collection: Under strict aseptic conditions, disinfect the venepuncture site using chlorhexidine with 70% alcohol swabs, allowing the site to completely dry. Draw 0.5-1.0ml of blood and place it in paediatric aerobic bottle. Fill the necessary requisition forms. All the paediatric aerobic bottles were sent to Microbiology laboratory.

Sample processing, identification and sensitivity

BD BACTEC 9050 System was used for incubation and the bottles were incubated until microbial growth was detected (BACTEC). BACTE 9050 is an automated blood culture system, which contains a sensor which responds to the concentration of CO_2 produced by the metabolism of micro organisms or the consumption of O_2 needed for the growth of micro organisms. The sensor is monitored by the instrument every ten minutes for an increase in its fluorescence, which is proportional to the increasing amount of CO_2 or the decreasing amount of O_2 present in the vial. BACTEC 9050 bottles that showed growth were plated onto sheep BA and MacConkey Agar and further incubated at 35+/- 2^0 C. Growth's were stained by Gram's method (WHO; Koneman's Color Atlas and Textbook of Diagnostic Microbiology, 5th edn). The positive growth was further processed by routine biochemical reactions and Antibiotic Susceptibility was put up by modified Kirby Bauer's method (Lalitha, 2004). CLSI guidelines were followed for interpretation of results (Collins *et al*., 1995; Forbes *et al*., 2002; Evans *et al*., 1996; WHO, 1980).

Results and Discussion

Our study analyzed the blood cultures from 1st January to 30th June 2016. A total of 100 Blood cultures were received from Pediatric ICU. Total blood cultures that came positive were 58. Out of 58, 28 samples yielded Gram Positive cocci (CONS-18, *S. aureus*-04, and *Enterococcus*-06) and 30 samples yielded Gram Negative Bacilli (*Klebsiella*-12, *E. coli*-02, *Citrobacter* -02, *Enterobacter*-12 and *Acinetobacter*-02). Most of the blood cultures grew within 72 hrs of incubation.

Table.1 Antibiotic used in the study

S.NO	Antibiotic	Potency	Abbreviations
1.	Amoxiclav	30mcg	AMC
2	Penicillin	10Units	P
3	Linezolid	30mcg	LZ
4	Vancomycin	30mcg	VA
5	Ampicillin	10mcg	AMP
6	Azithromycin	15mcg	AZM
7	Pipercillin/Tazobactum	100/10mcg	PIT
8	Cefoperazone/Sulbactum	30/15mcg	CFS
9	Cefoxitin	30mcg	CTN
10	Ceftriaxone	30mcg	CTR
11	Chloramphenicol	30mcg	C
12	Ofloxacin	5mcg	OF
13	Cefepime	30mcg	CPM
14	Amikacin	30mcg	AK
15	Imipenem	10mcg	IPM
16	Ceftazidime-Clavulanic acid	30/10mcg	CAC

Table.2 Number of organism isolates from culture positive neonates

Isolates	Frequency of isolates (%)
CoNS	18 (31.03%)
Klebsiella spp.	12 (20.68%)
S.aureus	04 (6.89%)
Enterococcus	06 (10.34%)
E.coli	02 (3.44%)
Citrobacter	02 (3.44%)
Enterobacter	12 (20.68%)
Acinetobacter	02 (3.44%)

Neonatal septicemia refers to generalized bacterial infection documented by positive blood culture in first five weeks of life. It is the major cause of mortality and morbidity accounting for 30-50% neonatal deaths in developing countries. In India a lot of neonatal mortality is accountable by septicemia and its treatment failure due to emergence of drug resistance. The fact is that the isolated organisms have developed increased drug resistance over the last few years. Most of the Laboratories in India use conventional Glucose broth/BHI broth for Blood culture routinely. Use of BACTEC PEDS PLUS bottles is intended to maximize the yield of obligate aerobes and anaerobes. BACTEC BD bottles not only yielded Gram Positive cocci, but also Gram Negative bacilli, they also showed positive cultures in patients with single dose of Antibiotics, since the Antimicrobial activity is neutralised by resins present in the bottles. Blood cultures remain a valuable microbiological test for diagnosis of Septicaemia. Automated blood culture methods significantly reduced the time required for processing of samples and also facilitated yield of GPC and GNB.

Neonatal septicemia remains a major clinical problem with high morbidity and mortality rate, especially in developing countries like India. The present study showed that gram negative bacteria were the most prevalent cause of infections in neonates in our hospital. *Klebsiella* spp. was the most commonly isolated gram negative organism whereas CONS were the most commonly isolated from gram positive organism. Drug resistance to conventional antibiotics is a common problem. As neonatal septicemia is considered a life threatening Emergency condition, prompt treatment with antibiotics is necessary. WHO has recommended the use of pencillin or ampicillin plus an aminoglycoside for neonates. The present study showed Imipenem, piperacillin tazobactum, Cefaperazone sulbactum and Ceftazidime-clavulunic acid are more effective drug for the treatment of gram negative organisms. Linzeolid, Vancomycin shows 100% susceptibility for gram positive organisms and more effective drugs for the treatment of gram positive isolates. So, it will important to continue surveillance of neonatal sepsis in order to follow closely changing in trends and risk factor to obtained information for empiric antibiotic therapy and to react rapidly in case of major changes in susceptibility patterns and occurrence of outbreaks.

ABSTRACT

Background: Rapid and accurate detection of methicillin resistant *Staphylococcus aureus* (MRSA) is an important role of clinical microbiology laboratories to avoid treatment failure. The aim of this study was to compare conventional methods against the cefoxitin disc diffusion method to determine the best phenotypic method.
Methods: Study was carried out in the Department of Microbiology, National Institute of Medical Sciences & Research, Jaipur (India), between July 2016 – December 2016. The methods included were Oxacillin E-test MIC, Oxacillin screen agar, Oxacillin disk diffusion, Cefoxitin disk diffusion and CHROMagar- MRSA methods. Antimicrobial susceptibility performed as per CLSI guidelines.
Results: Out of 142 isolates of *S. aureus*, fifty three (37.32%) strains of MRSA were isolated from clinical specimen. E-MIC test was selected as gold standard method. The sensitivity and specificity of Oxacillin screen agar and CHROMagar-MRSA were same 98.07% and 97.80%, respectively. The sensitivity and specificity of oxacillin disk diffusion were 94.23% and 98.89%. Fifty three strains of *S. aureus* were MRSA by cefoxitin disk diffusion method and Oxacillin Ezy MIC test. The sensitivity and specificity of cefoxitin disk diffusion method and Oxacillin Ezy MIC method was 100% and 100% respectively. All isolates including MRSA were susceptible to Vancomycin and Linezolid.
Conclusions: All phenotypic methods had high sensitivity and specificity for detection of MRSA. However, cefoxitin disk diffusion method in comparison to other methods had higher sensitivity and specificity.

INTRODUCTION

Staphylococcus aureus is an important etiological agent of hospital and community acquired infections.[1,2] The organism has a potential to spread and is reason of outbreaks particularly in hospitals.[3] Methicillin resistant *S. aureus* (MRSA) was first reported in 1961. Now a day matter of concern for microbiologist and clinician is how to overcome methicillin resistance problem.[4] The importance of MRSA as a nosocomial as well as community acquired pathogen is well documented.[5,6] Emerging of MRSA worldwide has led to the overuse of glycopeptides antibiotics, and to the emergence of Vancomycin resistant *S. aureus*.[7] Methicillin resistance in *S. aureus* is mediated by the *mecA gene* which codes for an additional penicillin binding protein, PBP2 or PBP2a.[8] MRSA strains are frequently resistant to many different classes of antibiotics, second and third-line antimicrobial

resistance is a growing concern.[9] Considering the increasing rate of infections caused by MRSA, performance of reliable, accurate and rapid testing for detection MRSA is essential for both antibiotic therapy and infection control measures.[10] There are many molecular and conventional phenotypic methods are available for detection of MRSA in clinical microbiology laboratories. Molecular methods are not affordable by every laboratory especially in India, so it is essential to evaluate an accurate sensitive method which can provide equivocal results with molecular methods.

The aim of this study was to determine the incidence of methicillin resistance and to compare various methods for detection of methicillin resistance with Cefoxitin disc diffusion method at National Institute of Medical Sciences and Research located in Jaipur. E-MIC test was selected as gold standard method.

METHODS

Sample processing

This is a prospective study and the clinical isolates of *S. aureus* from different specimens including tracheal aspirates, wound and soft issue, urine, blood and other specimens between July 2016 to December 2016 in National Institute of Medical Sciences & Research, Jaipur, 142 strains of *S. aureus* isolated from patients admitted to our hospital were included. The majority of patients were hospitalized patients. Briefly, the samples were cultured aerobically in blood and MacConkey agar. The plates were incubated overnight at 37ºC. All isolates were identified using gram stain, biochemical tests including catalase, coagulase. Antimicrobial susceptibility testing of MRSA isolates by Modified Kirby Bauer disk diffusion method (MKBDDM) as per CLSI Guidelines 2016.[11]

Methicillin resistance detection

1. *Cefoxitin disk diffusion*

All strains of *S. aureus* were tested with 30 mg cefoxitin discs (Hi-Media) on Mueller–Hinton agar plates. For each strain, a bacterial suspension adjusted to 0.5 McFarland was used. The zone of inhibition was determined after 16–18 h incubation at 37^{0}C. Zone size was interpreted according to CLSI (2016) criteria: susceptible, >22 mm; resistant, <21 mm.[12]

2. *Oxacillin disk diffusion*

All strains of *S. aureus* were tested with 1 mg oxacillin discs (Hi-Media) on Mueller–Hinton agar with an addition of 4% NaCl. For each strain, a bacterial suspension adjusted to 0.5 McFarland was used. The zone of inhibition was determined after 16-29 h incubation at 35^{0}C. Zone size was interpreted according to CLSI (2016) criteria: susceptible, >13 mm; intermediate, 11–12 mm; and resistant <10 mm.[12]

3. *E-test method (Ezy MIC strip OXA 0.016 – 256 mcg/ml Hi-media)*

The conditions for testing include Muller- Hinton with 2% NaCl. The inoculum density was adjusted equivalent to 0.5 to 1.0 McFarland standards. The plates were swabbed accordingly. By the help of an applicator MIC strip on each plates was placed and were kept at 35^0 C for 24 hrs. The MIC less than 2 ug were considered sensitive and more than 4 ug as resistant.[13]

4. *Oxacillin screening Agar (Oxacillin resistance screening agar base Hi-media)*

This method requires suspending test organism to the density of 0.5 McFarland and inoculating MH agar containing 4% NaCl and 6 mg/ml oxacillin with a spot or a streak of the organism. Plates were incubated at 35^0 C for 24hrs. Any growth other than a single colony was considered as resistant.[14]

5. *MRSA CHROMagar (Hi Crome MeReSa agar Hi-media)*

CHROMagar (Hi-Media) is a new chromogenic medium for the identification of MRSA. For each strain, a bacterial suspension adjusted to 0.5 McFarland was used. Subsequently, a swab was dipped in the suspension and streaked onto a CHROMagar plate. The plates were incubated at 35^0 C for 18-24 hrs. The growth of any green color colony was considered to be MRSA positive.[15]

S. aureus ATCC 25923 was used as a control strains for quality control.

RESULTS

Out of 142 isolates of *S. aureus*, fifty three (37.32%) strains of MRSA were isolated from clinical specimen. E-MIC test was selected as gold standard method. All isolates of MRSA were 100% susceptible to vancomycin and linezolid.

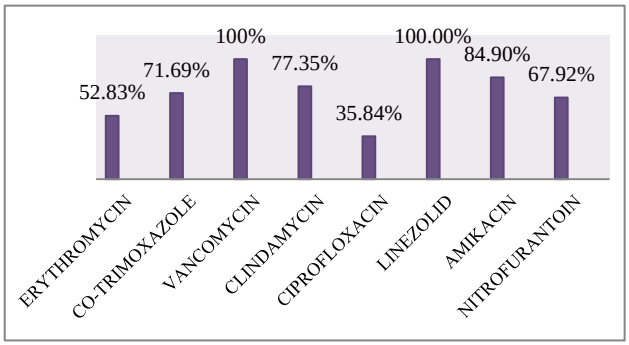

Figure 1: Susceptibility of MRSA isolates.

Table: 1 Sensitivity and Specificity of different methods.

Methods	Total No of MRSA	False -VE	False +VE	Sensitivity (%)	Specificity (%)	PPV	NPV
E-test	53	00	00	100.00	100.00	100	100
CHROMagar	50	01	02	98.07	97.80	96.36	98.89
OXA. Screen AGAR	50	01	02	98.07	97.80	96.36	98.89
Cefoxitin disk diffusion	53	00	00	100	100.00	100	100
Oxacillin disk diffusion	49	03	01	94.23	98.89	98.15	96.74

Sensitivity and specificity of different methods is illustrated in Table 1. The result of susceptibility testing of MRSA isolates to other antibiotics is shown in Figure 1.

Table 1 show the E-test method and Cefoxitin disk diffusion method gives 100% sensitivity and specificity comparison to other tests for the MRSA detection.

Figure 1 shows the vancomycin and linezolid drugs are higher sensitive comparison to other drugs and both are drug of choice for the treatment of MRSA patients.

DISCUSSION

Testing of methicillin resistance in *S. aureus* has been a challenge for clinical laboratories for many years. Several studies have shown that detection of *mecA* gene is a gold standard method for diagnosis of MRSA in clinical microbiology laboratories, but most of the developing countries cannot afford molecular methods in routine due to its high cost, so it is essential to evaluate an easy, cost effective, accurate and sensitive method for MRSA detection that can be used in routine lab and also which can give equivocal results with molecular method.

In the present study, we evaluated five different phenotypic methods for the detection of MRSA. A total 142 *S. aureus* were isolated from different clinical samples. All of the 142 *S. aureus* isolates were processed for methicillin detection by the cefoxitin disc diffusion test as described above in material method section. 53 (37%) were observed as Methicillin Resistant *S. aureus* (MRSA) by cefoxitin disc test with 100% sensitivity and 100% specificity.

These 53 MRSA strains were then compared with oxacillin disc diffusion test, oxacillin screen agar, MRSA chrome agar and E-test strip method, we observed 49 strains as true MRSA, 3 as false negative MRSA and 1 isolate as false positive MRSA by oxacillin disc diffusion test with 94.23% sensitivity and 98.89% specificity. 50 strains detected as true MRSA, 1 false negative MRSA and 2 false positive MRSA by oxacillin screen agar with 98.07% sensitivity and 97.80% specificity. Similarly 50 strains were detected as true MRSA, 1 false negative MRSA and 2 false positive MRSA by chrome agar method with 98.07% sensitivity and 97.80% specificity. The E- test strip method gave equivocal results to cefoxitin disc diffusion test i.e. 53 strains were confirmed as true MRSA with 100% sensitivity and 100% specificity.

There is variation among the results reported regarding sensitivity of different conventional methods used for detection of MRSA by number of authors.[16] However, most of the studies reported 100% sensitivity and 100% specificity with cefoxitin disc diffusion method which is in accordance with our results.[17] Karami et al depicted 100% sensitivity and 100% specificity with E Test MIC which is also similar to our observation.[18]

Our observation does not suggest oxacillin disc diffusion, oxacillin screen agar and MRSA chrome agar to be used in routine as there are chances of misinterpretation ultimately risk of treatment failure which is not acceptable and affordable at any cost. E test MIC detected all of 53 isolates as true MRSA that can also be an alternate to molecular method also it is easy to perform in routine.

Recently CLSI has replaced oxacillin with cefoxitin for detection of MRSA. Regarding cefoxitin disk diffusion, many studies reported that the results of cefoxitin disk diffusion tests correlate better with the presence of *mecA* than do the results of disk diffusion tests using oxacillin. In a study by Anand et al, results of cefoxitin disk diffusion method for detection of MRSA were in concordance with the PCR for *mecA* gene.[17] Another study by Anupurba et al, showed a high correlation between MICs of cefoxitin and presence of *mecA* in staphylococcus spp. Recently it is shown that cefoxitin disk diffusion method is more reliable than oxacillin disk diffusion method for detection of MRSA.[19]

In our hospital, 37.32% of all *S. aureus* infections are caused by MRSA. Susceptibility test profiles revealed a higher level of resistance to commonly prescribed antimicrobial agents among MRSA. All isolates were sensitive to Vancomycin and Linezolid. These results were comparable to studies carried out by others (Anupurba et al).[19] In the present study the antibiotic sensitivity pattern of MRSA included Erythromycin (52.83%), Co-trimoxazole (71.69%), Clindamycin (77.35%), Ciprofloxacin (35.84%), Nitrofurantoin (67.92%) and Amikacin (84.90%). Vancomycin and Linezolid are (100%) susceptible to all MRSA isolates. In other study conducted by Datta et al, also found (100%) MRSA strains were sensitive to Vancomycin and Linezolid.[12]

CONCLUSION

In our study we found that the cefoxitin disc is a good method for MRSA detection but it should be supplemented with some other method so that no MRSA is missed. No other method (oxacillin disc diffusion, MRSA chrome agar and oxacillin screen agar method) was as sensitive and specific as cefoxitin disc diffusion test and Oxacillin E test strip was so it is advisable to combine two methods, one with high sensitivity and the other with high specificity. According to our results, the best combination is the cefoxitin disc diffusion method and the Oxacillin E- strip test. Since the Oxacillin E- strip test is expensive it cannot be applied to all tests. Therefore, isolates that give a zone diameter of less than 20 mm can be easily reported as MRSA and only those with zone diameters of 20–22 mm need to be confirmed by Oxacillin E- strip.

ABSTRACT

Background: South Asian countries constitute 22% of world population and 40% of developing world and account for more than 40% of global burden of stroke death[1]. There are insufficient studies available on ischemic stroke in Asian countries including India.

Aims: The present study aimed at evaluating risk factors, clinical profile and stratification of ischemic Stroke subtypes based on TOAST categories among patients admitted in a tertiary care hospital, in North India.

Methods and Material: An Observational prospective hospital based Study was carried out on patients of acute Ischemic stroke admitted within 7 days of symptom onset to a tertiary care hospital during June 2015 to December 2016 who were suitable as per our inclusion and exclusion criteria.

Results: A total of 164 acute ischemic stroke patients were enrolled during the study period. Acute ischemic stroke was found comparatively more in Male patients [71%] than in females [29%]. More than one fourth of patients were between 61-70 years (28%) followed by 51-60 (23.8%). The most common risk factors were Hypertension (56.1%) followed by Diabetes (40.2%). The most common clinical presentation was limb weakness in (70.7%) of patients followed by dysarthria (58.5%).The most common subtypes of acute ischemic stroke was undetermined etiology (UDE) in 34.7% followed by Stroke of other determined etiology in 24.3% .

Conclusions: The present study suggests that male and middle aged individuals are at increased risk of having acute ischemic stroke. The commonest risk factor in our study was Hypertension, followed by diabetes, CAD, smoking and tobacco chewing. The most common etiology of ischemic stroke was stroke of undetermined etiology.

KEYWORDS

Ischemic stroke, risk factors, clinical presentation, hypertension, North India.

INTRODUCTION

Stroke is the 2nd leading cause of death and third leading cause of disability worldwide[2]. Globally, 70% of strokes and 87% of both stroke-related deaths and disability-adjusted life years occur in low- and middle-income countries (LMIC)[3-5]. The disability in LMIC like India, largely driven by demographic changes and further enhanced by the increasing prevalence of the key modifiable risk factors. So there is double whammy for LMIC as both primary prevention and stroke treatment is not up to the mark.

Hence the present study aimed at Stratification of ischemic Stroke subtypes and to identify the common modifiable and non- modifiable risk factors along with clinical presentation among ischemic stroke patients in North India.

Subjects and Methods

Study Population:-

The present study was undertaken after obtaining permission from the institution's research and ethical committee. Patients of acute Ischemic stroke admitted within 7 days of symptom onset to a tertiary care hospital during June 2015 to 31stDecember 2016 who were suitable as per our inclusion and exclusion criteria were included in the study.

Inclusion criteria:

- Patients of all age group diagnosed as having acute ischemic stroke within 7 days of symptom onset, based on the imaging study (MRI or CT scan) during the study period.

Exclusion criteria:

- All other patients not willing to give an informed consent, stroke mimics and ICH were excluded from the study.

Study Design:-Observational prospective hospital based Study

Sample Size

For the margin of error at 2% and confidence level of study at 99%, a minimum of 136 patients (calculated using Raosoft sample size calculator and based on similar previous studies reported prevalence of stroke is 83%)[6] were required for Evaluation of clinical in different subtypes of ischemic stroke and to Assess Prognosis of patients in different sub types of ischemic strokes. So the sample size in our study was minimum of 136 patients.

Methodology-

- An informed consent of each patient studied prospectively was obtained.
- A detail history in terms of name, age, sex, chief complaints, past and family history was taken. History related to etiological factor like smoking, diabetes, hypertension, previous stroke, history of atrial fibrillation, dyslipidemia, malignancy etc. was noted.
- Diabetics- Patients who are known diabetics, or newly diagnosed (HbA1C ≥6.5%)
- Hypertension- Patients on antihypertensive medication or having previous history of hypertension.
- Dyslipidemia- Total cholesterol >200mg/dl and /or LDL cholesterol >100mg/dl.
- Smoking- 10 or more cigarette or Bidi per day for at least 6 months
- Alcoholic- on average ≥ 2 drinks/day for males and ≥ 1 drinks for females (previous drinker: ex drinker for more than 1 year).
- Tobacco Chewer – History of tobacco chewing
- Hypothyroidism- History of hypothyroidism or newly diagnosed
- Renal disease- History of chronic kidney disease (Stage I-V) or newly diagnosed.
- CAD- History of angiographically proven CAD.

Subtypes of ischemic stroke

Clinical examination of patient was done including general physical and neurological examination with parameters like baseline NIHSS**,** Pupils, Cranial nerves examination, Muscle Tone, Power in limbs, Deep tendon reflexes, Sensory examination, Cerebellar signs. Based on clinical and radiological findings patients were classified in different TOAST categories

Data processing and analysis

All the analysis was carried out on SPSS 16.0 version (Chicago, Inc., USA) with statistical significance at <0.05.

Results

A total 164 acute ischemic stroke patients were enrolled during June2015 to December 2016 and were evaluated for risk factors, clinical presentation and stroke subtype.

Demographic profile

In the current study, acute ischemic stroke patients was found comparatively more in Male patients i.e. 117 [71%] than in female

patients 47 [29%]. The male to female ratio was 2.49:1. The mean age was 57.77±15.16 years for males and 62.19±14.54 years for females, More than one fourth of patients were between 61-70 years (28%) followed by 51-60 (23.8%), >70 (22%), <40 (14%) and 41-50 (12.2%) years. (Figure 1-3)

Risk factor profile

Among ischemic stroke patients, 92 (56.1%) were hypertensive, 66 (40.2%) were diabetic and 24 (14.6%) had dyslipidemia. History suggestive of coronary artery disease was present in 36 (22%) patients, atrial fibrillation was present in 16 (9.8%) patients, and 10 (6.1%) patients each had rheumatic heart disease and Renal disease. Family history suggestive of stroke was present in 23(14%) patients and previous history of stroke was found in 14% patients. Smoking habit was seen in 12.8% patients and tobacco chewing habit was seen in 6.1%. Alcoholic were 3%. (Figure 4-6)

Figure 7 is showing distribution of patients with recurrent stroke according to the time interval from the previous stroke. Maximum (39.1%) patients had previous stroke between 1-5 years followed by 30.4% of patients within 3months to 1 year and 26.1% before 5 year. Only 4.3 % of patients were having stroke within 3 months of previous stroke.

Clinical presentation

Figure 8 is showing distribution of symptoms in acute ischemic stroke. Acral weakness was the most common symptom present in 70.7% of patients followed by dysarthria (58.5%), aphasia (22.6%) and ataxia (11.6%). Other uncommon symptoms were Loss of consciousness (11%), headache (7.3 %), vertigo (1.8%), seizure (1.2%), visual loss (1.2%), and altered sensorium (0.6%).

Ischemic stroke subtype

An important objective of our study was to classify the patients in to subtypes of acute ischemic stroke. Despite extensive evaluation , etiology remained undetermined in 34.7% (UDE). Stroke of other determined etiology in 24.3%, small vessels (20.7%), large artery atherosclerotic disease in12.8% and Cardio-embolic in 7.3 % patients were seen. Stroke of other determined etiology was identified in 40 patients (24.3%), which included hyperhomocysteinemia in 33 (82.5%), malignancy in 4(10%), Antiphospholipid syndrome in 1 (2.5%), dissection in 2(5%) patients. (Figure 9-10)

DISCUSSION

The present observational prospective hospital based Study provides advance and unique data on clinical presentation, etiological and risk factors of ischemic stroke in a section of Indian population. Out of 164 acute ischemic stroke patients, 117 [71%] were male and 47 [29%] were female (p =0.08). Male to female ratio in our study was 2.49:1. This gender differentiation is similar to other studies reported by Raghuvanshi S. et al[7], Marulaiah S.K. et al[8] and Kashinkunti et al[9]. The male to female ratio is comparable to other studies conducted by Raghuvanshi S. et al[7]., from Bhopal and Parvaiz A Shah et al[10]., from Kashmir showing a M:F ratio of 2.89:1 and 2.4:1 respectively. The above studies concluded that stroke is more common among men than women. Male sex is one of the strong risk factor for stroke. Women have lower stroke incidence than men because of genetic factors, positive effects of estrogen on the cerebral circulation, and low blood pressure levels. Moreover, ischemic heart disease, peripheral artery disease and cigarette smoking are more prevalent among male stroke patients[11].This gender difference probably resulted from inherent social bias, in which female patients are less likely to be admitted to hospital compared to male patients which is less likely in urban setting. This observation is in contrast to the study done by Yadav R.S. et al[12] in which there was female predominance in ischemic stroke patients; may be due to disorders related to pregnancy, excess use of contraceptive pills and also stroke in females due to migraine in these studies.

In our study, the mean age of patients of acute ischemic stroke at presentation was 57.77±15.16 years for males and 62.19±14.54 years for females. More than half of the patients were in the age group of 51–70 years (51.8%).Young patients with ischemic stroke (age ≤50 years) comprised of 26% of the cohort while 7.3% were in age group of >80 year.The above mentioned observations are similar to studies conducted by Grau AJ et al[13], Acciarresi M et al[14], in which ischemic stroke mean age for males was lower females (59.3±13.6 versus 66.85±14.9).This is dissimilar to studies conducted by Al-Rajeh S et al[15],El Sayed MM et al[16]., in which stroke occurred at a younger age in women than men. The age distribution in our study is similar to studies carried out by Yadav R.S. et al[12] and Marulaiah S.K. et al[8], with 45.5% were 51-70 years, and 51% patients in 51-70 years, respectively. The data of young ischemic stroke is comparable with the studies done by Misbach and Wendra et al[17], and Eapen et al[18], with incidences of young patients with ischemic stroke were 12.9% and 15.4% respectively. Stroke at earlier age has been shown by various studies conducted in India[7].

The mean age of stroke in present study was 59.04±15.07 years which is comparable to study conducted by Raghuvanshi S. et al[7] (Indians) 53.02±12.45 years versus (Americans) 71 ± 13 years. In comparison with the studies carried out by Kissela et al[19], and Baidya et al[20], the mean age of the patients with stroke is relatively lower in our study. It is possibly because of lack of preventive strategies in place regarding various risk factors of stroke at the population level.

In the present study, hypertension was the most common risk factor among the stroke patients (56.1%). Diabetes was the second most common (40.2%) and CAD was the third most common disease (22%). This is similar to study conducted by Nadia Aquil et al[21], in which hypertension was most common with (55%), diabetes mellitus (49%), CAD in (30%) and dyslipidemia in 22% patients. Similar trend was seen in study conducted by N.A. Syed[22], in which hypertension was reported as the most commonest risk factor (66.2%), followed by diabetes mellitus in 41.5% patients. In study by Marwat et al[23], hypertension was the most common risk factor (75%) followed by diabetes mellitus (54.5%), IHD (36.3%), hyperlipidemia (13.6%) and valvular heart disease (6.8%).

In contrast to the present study, Vaidya et al[24], reported that the most common risk factor was hypertension with (30.1%) incidence, second most commonest was CAD (16.1%), dyslipidemia (15.6%) and diabetes mellitus in 10.8% patients. A study by Misbach and Wendra et al[17]., hypertension was the most important risk factor for ischemic stroke, as other risk factors were hyperlipidemia, diabetes mellitus, IHD and atrial fibrillation.

Hypertension has been observed the most common risk factor of ischemic stroke in various studies. This alarmingly high prevalence of hypertension in patients with ischemic stroke calls for need of treatment of major public health problems and indicates the need to incorporate treatment of hypertension into health care policy measures in order to reduce morbidity and mortality of stroke. Also the risk of stroke in diabetic patients is about double than that found in non-diabetic individuals[25].

Out of 164 patients, 21 (12.8%) were smokers,6.1% patients were tobacco chewer and only 3% patients were alcoholic.This is comparable to the study done by Deepa Dash et al[26] and Azra Zafar et al[27], who found smoking in 9.5% and 7.2% patients respectively but is in contrast to studies conducted by Raghuvanshi S et al[7] and Yadav RRS et al[12], in which the smoking rate was much higher ie 44% and 23.8% respectively. The observation of tobacco chewing habit is comparable to the study conducted by Raghuvanshi S et al[7]., in which 10% patients were tobacco chewer, a slight high rate of tobacco chewing is noticed in study conducted by Yadav RRS et al[12], ie 14.8%. The alcoholics (3%) are comparable to the study done by Vaidya C et al[25], with 6.6%. This is much lower than the studies conducted by Eapen RP et al[18], and Naik M et al[28], who found 35.3% and 30.5% alcoholics respectively. The current study had a reduced frequency of smoking, tobacco chewing and alcoholics compared to previous Indian studies. A bias due to suppression of history of addiction may be responsible for some reduction.

In the present study, previous history of stroke was found in 14% patients. This figure is generally in agreement with studies conducted by Raghuvanshi S et al[7], and Yadav RSS et al[12]., with history of stroke in 13.7%, and 9.8% patients respectively. Maximum (39.1%) patients had previous stroke between 1-5 years followed by 30.4% of patients within 3 months to 1 year and 26.1% before 5 year. Only 4.3 % of patients were having stroke within 3 months of previous stroke in the present study.

The most common stroke subtype in the present study was undetermined etiology(34.7%)followed by stroke of other determined cause (24.3%), small vessel disease (20.7%), large vessel disease

(12.8%) and cardioembolic stroke (7.3%). This is comparable with the study done by Yatsu FM et al[29] and Kunitz SC et al[30] in which 33% and 33% patients were remained in stroke of undetermined etiology. This is much higher than the previous studies done by Kaul S. et al[31] in 27%, Raghuvanshi S et al[7] in 21.7% and Nadia et al[21] in 18% patients. The most common reason for categorizing these patients as having an undetermined etiology was due to fact that a large number of patients had two or more etiological possibilities and some patients could not be evaluated extensively for stroke subtypes on account of various reasons. (Table1)

Stroke of other determined etiology was identified in 40 patients (24.3%).The most common etiology in this group was hyperhomocysteinemia in 33(82.5%), followed by cancer in 4(10%), Antiphospholipid syndrome in 1 (2.5%), dissection in 2(5%) patients. Similar to the study conducted by Kaul S et al[31]., in which Stroke of other determined etiology was identified in 17 patients (4%), in which hyperhomocysteinemia was the most common etiology ie in 8 (47.1%) patients, followed by anticardiolipin antibody in 4(23.5%) and dissection in 2(11.7%).A study conducted by Kumar SSS et al[32]., hyperhomocystenemia (55%) was predominantly seen followed by Protein S deficiency, Protein C deficiency and antithrombin III deficiency in 21%, 14% and 7% patients respectively and Antiphospholipid antibody (APLA) was positive in 3% . In contrast to the study conducted by Deepa Dash et al[26]., reported the most common etiology in patients with ODC to be dissection (51.3%). Increased incidence of hyperhomocysteinemia in our study is probably due to slight higher incidence of smoking.

Third most common cause of ischemic stroke was small vessels etiology (20.7%).This is comparable to 18% reported previously by Parvaiz AS.etal[10], however, lower than 43% and 42.7% reported by Nadia et al[21] and Syed NA[22] et al respectively.

The frequency of cardioembolic stroke was 7.3% in this study. This is much lower than that reported from Sacco RL et al[33] (19%) and Raghuvanshi S et al[7] (16%) but comparable to 6% by Syed et al[22] and 10% by Kaul et al[31].

Most common symptom at presentation amongst patients of acute ischemic stroke was hemiperesis (70.7%) followed by dysarthria (58.5%)which was similar to the findings in study done by Vaidya.etal[24] . Weakness and dysarthria (58.5%) were also the most common symptoms in the study performed by Kumar NSSetal[32] where they found motor weakness in 94% of cases and dysarthria in 72% of cases. The higher occurrence of these symptoms in this study may be related to the higher percentage of anterior circulation stroke (86%) of patients. Other uncommon symptoms were aphasia (22.6%) loss of consciousness (11%), headache (7.3 %), vertigo (1.8%), seizure (1.2%), visual loss (1.2%) and altered sensorium (0.6%). Headache ataxia, vetigo and visual loss were associated with posterior circulation stroke.

Strength and limitations of the study

This is a prospective study with a relatively large sample size and also ensured uniform data collection of various risk factors related to stroke ,we obtained reliable information about clinical characteristics risk factors to achieve the goals of our study. This will in turn help the health care authorities to formulate the preventive strategies for management of risk factors and will also decrease the gravies effect of stroke by having overview knowledge about clinical characteristics of stroke.

There are certain limitations of our study. First, this study was confined to a single tertiary care hospital and thus represents a limited population. Moreover, this Hospital is a specialized neurology and neurosurgery hospital of India. The patients treated here are usually in a more critical condition as these patients are referred from the adjacent peripheral areas including rural and urban areas in and around metropolitan city, also referred from other neighbouring states and this may result in selection bias.

CONCLUSION

Our study suggests that acute ischemic stroke was maximum in male and middle aged patients. The most common preventable stroke risk factors were smoking, HTN, diabetes and CAD. The most common clinical presentation was limb weakness and dysarthia. Our study showed that most common subtype of acute ischemic stroke was stroke of undetermined etiology.

Considering the high morbidity and mortality associated with stroke, a large scale community based health awareness programme should be launched with the help of social group, local political leaders and healthcare workers. So that stroke can be recognized at its early stage and available treatment should be offered to the patients. It is also important for the local health care workers to know the acute ischemic stroke treatment guidelines.

To conclude, further similar studies on ischemic stroke, its clinical profile, risk factors should be encouraged, so that local risk factors of the defined area could be identified and shared with frontline healthcare workers, so that screening and management of common risk factors can be executed at the community level.

A B S T R A C T

In recent times, the treatment of Staphylococcus aureus infection has become problematic because of emergence of resistance to antibiotics which is a cause of concern for all the clinicians and microbiologists worldwide. Infections caused by MRSA have been associated with high morbidity and mortality rates. Hence this study was conducted to know the prevalence of Methicillin resistant Staphylococcus aureus [MRSA] isolates in various clinical specimens and to determine the sensitivity of these isolates to different antimicrobial agents. Among the 161 clinical isolates of S. aureus, highest isolation was from pus samples (64%), followed by blood (13%) and respiratory secretions (13%). 82 (51%) were identified as MRSA by Cefoxitin disc diffusion method and maximum MRSA were again isolated from pus (61%). Comparatively MRSA prevalence is more in males (73%) and most common affected age group was 21-30 years. All MRSA strains were resistant to penicillin (100%), followed by ciprofloxacin (93%) and erythromycin (61%). We found statistically significant differences in the drug susceptibility pattern of MRSA & MSSA for Penicillin, Clindamycin, Erythromycin, Ciprofloxacin, Co-trimoxazole and Levofloxacin. MDR-MRSA strains in our study is 45%. Hence we suggest, more and more studies in future are needed to fight against rising menace of antibiotic resistance among Staphylococcus aureus

Introduction

Staphylococcus aureus, the most clinically significant species of Staphylococci has been recognized as an important cause of human disease for more than 100 years (Ankur *et al*., 2013). It is one of the pathogens of greatest concern because of its intrinsic virulence factors, its ability to cause diverse array of life threatening infections, it's competency to adapt to different environmental conditions and its nasal carriage, which accounts for possible spread and re infection (Anupurba *et al*., 2003). Infections by *Staphylococcus aureus* are continuously challenging the clinicians despite the availability of antibiotics from nearly 70 yrs. This was due to the emergence of various types of antibiotic

resistance mechanisms especially to methicillin and vancomycin, which was the theme of several epidemiological studies (Arora *et al*., 2010; Assadullah *et al*., 2003).

With the introduction of Penicillin in 1940, it was thought that we can escape from the deadly threats of Staphylococcal infections, but no sooner in 1944 first strain of *Staphylococcus aureus* resistant to penicillin G appeared in London, mediated by the presence of penicillinase enzyme which hydrolyses the β-lactam ring of penicillin (Astagneau *et al*., 1996). By 1950s, penicillinase producing strains of *Staphylococcus aureus* were so common that penicillin became useless against Staphylococcal infections. To resolve this issue, in 1960 semi-synthetic penicillin (penicillinase stable penicillin) - like Methicillin came in picture, but availability of these agents did not stem the tide of resistance as within a year the first MRSA was reported from U.K. This was mediated by the presence of PBP-2a which is expressed by an exogenous gene, *mecA* (Bandaru, 2010).

In the past few decades MRSA has emerged as an important nosocomial pathogen worldwide. In India, prevalence rate varies from 30-85% in different parts and has now become endemic (Barber, 1961; Boucher, 2010). A multicentric study done in India involving 17 tertiary care Hospitals reported MRSA prevalence of 41% in 2008-2009 (Clinical and Laboratory Standards Institute, 2012), MRSA is of serious therapeutic concern not only due to its resistance to Methicillin, but also because of resistance to many other antimicrobials that are used on regular basis in Hospitals. Therefore, the most reliable and sustained therapeutic agent against methicillin-resistant *Staphylococcus aureus* (MRSA) strains is Vancomycin. Increasing prevalence of MRSA has lead to the extensive use of vancomycin. This inturn has lead to the decreased susceptibility to vancomycin. Such resistance is a serious clinical and public health consequences because currently few licenced alternatives are available to treat vancomycin resistant *Staphylococcus aureus* infections.

The association of Multidrug resistance with MRSA adds to the problem and the presence of MDR strains in the hospital cannot be neglected. Several studies are prevailing for Methicillin resistance from India but few have worked on Multi-drug resistance. MRSA strain showing resistance towards ≥ 3 antibiotics is defined as MDR strain and its prevalence ranges from 23% - 60% in India (Diep *et al*.,). The emergence of MDR MRSA infections is worrisome in the present therapeutic scenario. Keeping the above points in view, the present study was planned to find out the prevalence of MRSA among isolates of *Staphylococcus aureus* in various clinical specimens along with their antibiotic sensitivity pattern so as to guide the clinicians of our hospital to select appropriate antimicrobial agents and also to make them aware, that if inappropriate use these antibiotics is continued it may lead to impending public health disaster.

Materials and Methods

Source of material

The present study was conducted in the Department of Microbiology, GMCH, Udaipur, during the year 2013-2014. A total of 161 non- duplicate *Staphylococcus aureus* isolates from various clinical specimens [pus, wound or vaginal swabs, blood, body fluids (csf, pleural fluid, ascitic fluid) urine, sputum, ET secretion etc] were included in the study. Isolates from both in-patients and out-patients were considered. Institutional Ethical clearance was obtained. Data regarding age, sex, patient location, history of any clinical

illness etc. was obtained from the requisition form submitted to Microbiology Department, GMCH.

Inclusion criteria

All *Staphylococcus aureus* strains isolated from various clinical specimens, were included in the study.

Exclusion criteria

Clinical specimen's yielding growth of Gram positive cocci other than *Staphylococcus aureus* and all gram negative bacteria were excluded.

Isolation and identification of *Staphylococcus aureus*

All the isolates were identified by standard procedures (gram staining, catalase test, mannitol fermentation, Hugh-Leifson OF media, slide coagulase and tube coagulase test). Tube coagulase was taken as the main criteria of identification and was performed by diluting plasma in freshly prepared normal saline (1:6). Three to four colonies were emulsified in 1 ml of diluted plasma and the tubes were incubated at 37ºC. Readings were taken at 1, 2, 3 and 4 h and further incubated at room temperature if no clot formation was observed (Yogesh *et al*., 2013).

Determination of antibiotic susceptibility

All *Staphylococcus aureus* isolates were then subjected to antimicrobial susceptibility testing by modified Kirby–Bauer disc diffusion method. Antibiotics tested were Penicillin [10 units], cefoxitin (30 µg), Vancomycin [30µg], Linezolid [30µg], Pristinomycin (Quinupristin/Dalfopristin) [15µg], Gentamicin [10µg], Tetracycline [30µg], Chloramphenicol [30 µg], Ciprofloxacin [5µg], Levofloxacin [5µg], Erythromycin [15µg], Clindamycin [2µg], Rifampicin [5µg] and Cotrimoxazole [1.5/23.75µg]. *Staphylococcus aureus* ATCC 25923 was used as control strain. Zone of inhibition of all the antibiotics were measured with scale in reflected light against a black background, to the nearest mm. Interpretation was done according to the guidelines of Clinical Laboratory Standards Institute.

Detection of methicillin resistance

Cefoxitin disc (30 µgm) was used to detect methicillin resistant isolates as Cefoxitin, which is a potent inducer of the mecA regulatory system, is being widely used as a surrogate marker for detection of mecA gene-mediated methicillin resistance. MRSA strains exhibiting inducible resistance to methicillin grow much more readily in the presence of cefoxitin than oxacillin, due to an enhanced induction of PBP 2a by cefoxitin. Isolates with zone diameter of ≤21 mm were considered resistant to methicillin and zone of ≥22 mm were sensitive (Harcharan *et al*., 2014).

Results and Discussion

In the present study, a total of 161 non duplicate *Staphylococcus aureus* isolates were obtained from various clinical specimens. *Staphylococcus aureus* infection was found comparatively more in Male patients i.e. 115 [71%] than in female patients 46 [29%]. The male to female ratio was 2.5:1. Age group of 21-30 yrs and 51-60 yrs were predominantly affected. [Figure 1 and figure 2]. Among all *Staphylococcus aureus* isolates, majority contribution was from Pus samples 103 (64%), followed with blood 23(15%), respiratory secretion 18 (11%) and body fluids 7 (4%). Swabs and Urine samples grew only 7 (4%) and 3 (2%) respectively.[Table1] Out of total 161 Staphylococcus aureus strains, 82 (51%) were found to be MRSA

and79 (49%) were MSSA. Pus shown the highest prevalence of resistance towards methicillin i.e. (61%) followed by Blood (15%), Respiratory secretions (10%), body fluids (5%), Swabs (5%), and Urine (4%).[Figure 3, Figure 4] Comparatively MRSA prevalence is more in males (73%) and most common affected age group was 21-30 years.

Out of 161 *Staphylococcus aureus*, only 19 (12%) strains were sensitive to all antibiotics.[Table 2] Maximum resistance was shown by MRSA isolates. All the MRSA isolates were resistant to penicillin (100%) and all were sensitive to Linezolid, Pristinomycin, Chloramphenicol and Rifampicin. Among the MRSA strains, least sensitivity was showed by Ciprofloxacin (93%) followed by erythromycin (66%), Co-trimaxazole (54%), Levofloxacin (46%), Clindamycin (46%) and Gentamicin (30%). Tetracycline (6%), Vancomycin (3%) showed good efficacy.

Figure.1 Sex wise distribution of patients with *Staphylococcus aureus* infection

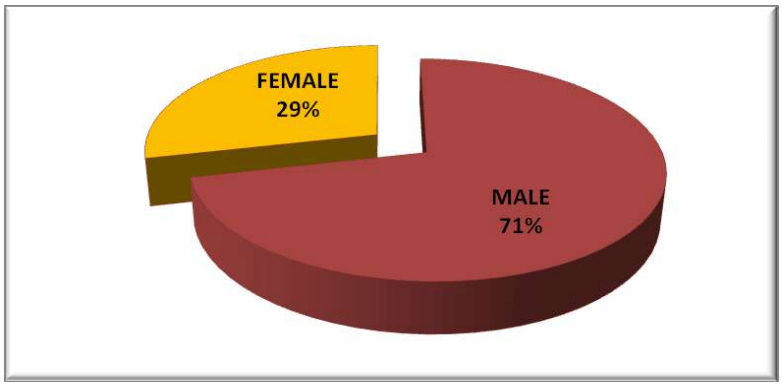

Figure.2 Age wise distribution of patients with *Staphylococcus aureus* infection

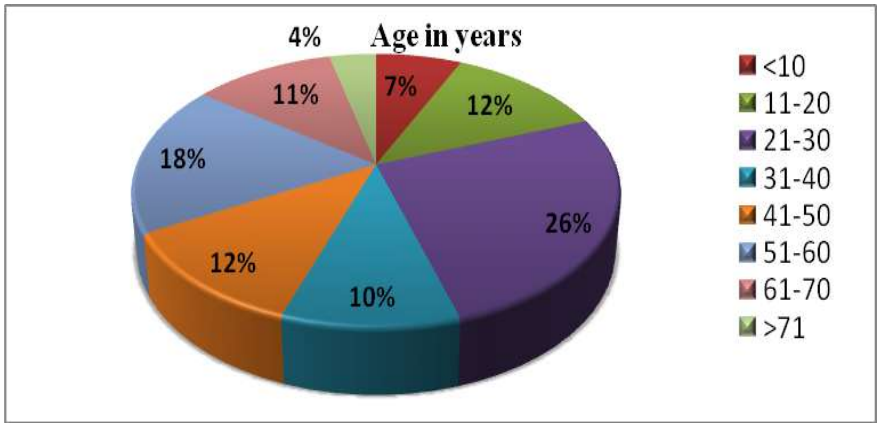

Figure.3 Total number of MRSA and MSSA in *Staphylococcus aureus* isolates

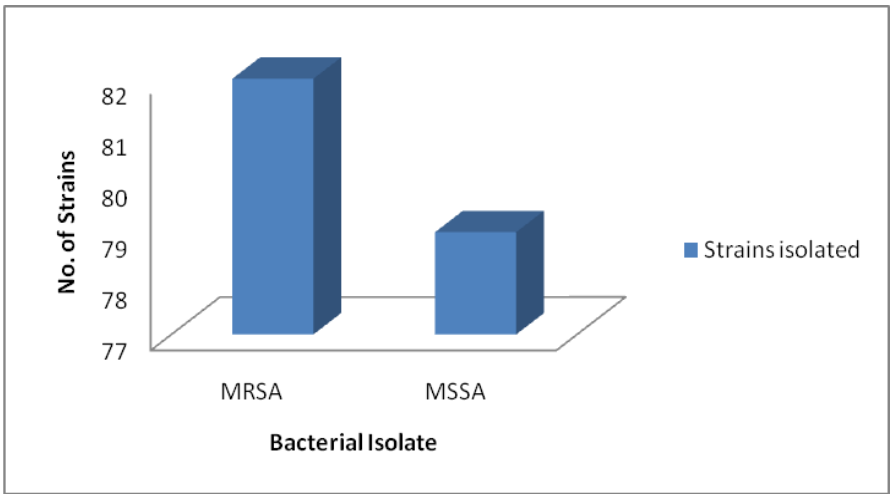

Figure.4 Specimen wise distribution of MSSA

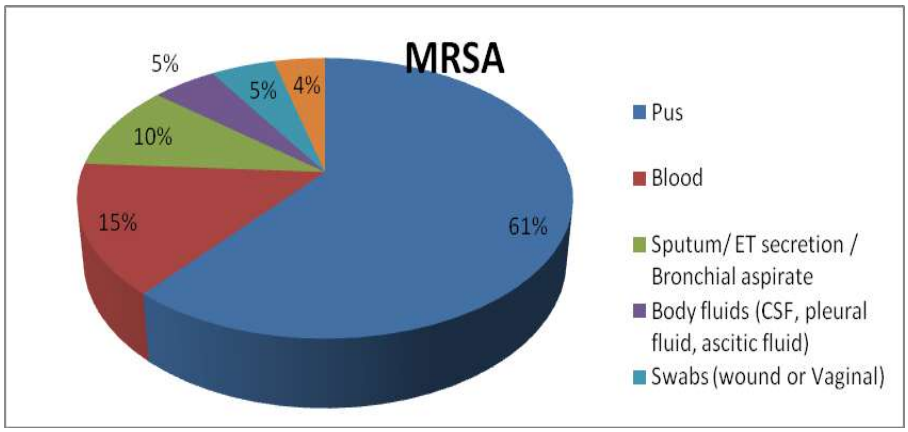

The sensitivity pattern of MSSA was quite different from the MRSA strains. All the MSSA strains showed cent percent sensitivity to Gentamicin, Tetracycline, Vancomycin, Linezolid, Pristinomycin, Chloramphenicol and Rifampicin. Levofloxacin showed the highest sensitivity (91%) among MSSA strains followed by Clindamycin (85%), Erythromycin (80%), Co-trimoxazole (67%), Ciprofloxacin (61%) and showed least sensitivity to penicillin (24%).(Table 3) Among all above mentioned drugs, antibiotic resistance for MRSA and MSSA was statistically significant only for Pencillin, Clindamycin, Erythromycin, Ciprofloxacin, Co-trimozole and Levofloxacin.(Table 4).

Staphylococcus aureus is a major human pathogen and is one of the commonest causative agent of Community and Hospital acquired infections. The treatment of *Staphylococcus aureus* infection has become problematic because of emergence of resistance to Penicillin, Methicillin, Vancomycin and many other antibiotics, by acquiring several resistance mechanisms. Increased antimicrobial resistance for such an organism is, therefore a cause of concern.

In the past few decades MRSA has emerged as an important nosocomial pathogen worldwide. In India, prevalence rate varies from 30-85% in different parts and has now become endemic (Lowy, 1998). A multicentric study done in India involving 17 tertiary care Hospitals reported MRSA prevalence of 41% in 2008-2009 (Mallick *et al*., 2010). MRSA is of serious therapeutic concern not only due to its resistance to Methicillin, but also because of resistance to many other antimicrobials that are used on regular basis in Hospitals. Therefore, the most reliable and sustained therapeutic agent against methicillin-resistant *Staphylococcus aureus* (MRSA) strains is Vancomycin. Extensive use of this antibiotic inturn lead to the emergence of Vancomycin intermediate *Staphylococcus aureus* [VISA] and Vancomycin resistant *Staphylococcus aureus* [VRSA] strains in various parts of the world (Manu *et al*., 2013).

In the present study a total of 161 non-duplicate *Staphylococcus aureus* strains were isolated from various clinical specimens. Among all these samples highest isolation was from pus 103 (64%). Harcharan singh *et al.,* (2014) in Udaipur (65%), Manu Chaudhary *et al.,* (2013) in H.P (63%) and Ankur Goyal *et al.,* in Agra (66.03%), also reported the highest isolation of *Staphylococcus aureus* from pus.

All the *Staphylococcus aureus* strains were screened for Methicillin resistance using Cefoxitin disc diffusion method. Since it is a potent inducer of *mecA* gene, hence considered as a surrogate marker for detection of methicillin resistance by CLSI 2012, in our study 82 (51%) isolates turned out to be MRSA and 79(49%) as MSSA, from a total of 161 *Staphylococcus aureus* strains. The prevalence rate of MRSA in our institute is 51%, which is similar to the studies conducted by Vidhani and Mehndiratta *et al*., in 2001 showing a prevalence rate of 51.6% and almost comparable to the study conducted by Majumdar *et al*., in 2001 and Assadullah *et al*., in 2003 showing 52.9% prevalence rate. The higher rate in their studies may been attributed to the fact that the studies were conducted at a tertiary care multispecialty center with more and more patients coming from pheriphery and small nursing homes, where injudious use of antibiotics and inadequate infection control policies are prevalent. Verma *et al*., in 2000 reported a higher prevalence rate of 80.89% in Indore and Mehta *et al*., in 2007 reported a lower prevalence rate of 24% in Chandhigarh. This variation in prevalence may be because of several factors like different Geographical and

environmental conditions, population group under study, healthcare facilities available in the particular hospital, implementation and monitoring of infection control committee, rationale antibiotic usage which varies from hospital to hospital. We have 51% prevalence rate of MRSA in our hospital setup. It therefore calls in for better vigilance and implementation of more effective MRSA surveillance programme complemented with improved infection control practices.

In the present study, maximum MRSA were isolated from pus 50 (61%), followed by blood 13(15%), respiratory secretions 8 (10%), Swabs and body fluids 4(5%) each and least from Urine 3(4%). This pattern correlates with studies conducted by Vidya Pai *et al.,* in 2010 and Nitish Kumar Sharma *et al.*, 2013. This is due to the reason that *Staphylococcus aureus* accounts for most of the skin and soft tissue infections, septicemia and also respiratory tract infection.

Comparatively MRSA prevalence was more in males (73%) than in females (23%) in our study. Similar findings was also reported by Rao *et al*., (2010) and Abhishek Mewar *et al*., The increased rate of MRSA infections among males could be due to their more outdoor activities, inturn exposing them to contaminated environment and also compared to females, accidental injuries are more common among men.

Most of the MRSA strains were isolated from 21-30 yrs of age group (ie 32%) and in 51-60yrs (ie 26%), indicating MRSA infection is more common in working and old age group. The reason for this may be that younger age group are more involved in outdoor activities inturn exposing them to contaminated environment and in older age group it may be due to waning immunity, hormonal abnormalities and co-morbid conditions. Similar pattern of affected age group was also reported by Ankur Goyal *et al*., in 2013. Isolation was more from the IPD patients (88.8%) than from the OPD patients (11.2%). Among IPD patients, highest prevalence was seen in orthopedics, oncology and surgical wards. Similarly Mallick and Basak reported 84.8% MRSA from IPD patients, in which maximum strains were isolated from surgical and orthopedics ward. This might be because the patients in these wards are usually with open wounds and are debilitated. They undergo multiple interventions in the hospital which further increases the risk of MRSA infection due to multiple people involvement as well as prolonged stay in the wards. Along with these factors, the patient is usually on multiple antibiotics.

Resistance of MRSA to a wide range of antibiotics is well documented[35]. In the present study antibiotic resistance is significantly more in MRSA strains of *Staphylococcus aureus* as compared to MSSA strains. Statistically significant difference was observed for Penicillin, Fluoroquinolones, Erthromycin, Clindamycin and Co-trimoxazole. Such similar statistically significant difference between the sensitivity pattern of MRSA and MSSA was also reported by Vidhani *et al*., (2013), Shilpa Arora *et al*., (2013) Majumder *et al*., (2013).

For Penicillin 100% resistance was observed for MRSA strains in our study and such similar finding was also reported by Gupta *et al*., (2010), Anupurba *et al*., The resistance rate of Ciprofloxacin in MRSA strains was high [93%], consistent with the resistance rate of Pulimood *et al*., [90%] and Udaya Shankar *et al*., [95.8%]. Our study had also showed high degree of resistance to Erythromycin and Co-trimoxazole. Such high resistance pattern observed for these antibiotics in our study may be due to the differential clonal expansion and indiscriminate empirical use of these drugs. The present study also showed a low level of resistance to Clindamycin, similar to the study conducted by Ankur

Goyal *et al*., (2013). This may be due to the antibiotic recycling and the dependence of the clinicians more on beta lactam drugs. In the light of the present study, we would recommend use of Clindamycin for the management of soft tissue infections, with MRSA strains that are sensitive to Clindamycin since it has better soft tissue penetration and no renal dosing adjustments and thus by reserving Vancomycin for life threatening infections.

The association of Multidrug resistance with MRSA adds to the problem and the presence of MDR strains in the Hospital can't be neglected. Several studies are prevailing for Methicillin resistance from India but few have worked on Multi-drug resistance. MRSA strain showing resistance towards ≥ 3 antibiotics is defined as MDR strain. MDR MRSA strains in our study is 45%, a study conducted by Majumder *et al*., (2013) reported 23.2% MDR- MRSA, 32% by Anupurva *et al*., and as high as 63.6% by Rajaduraipandi *et al*., (2000). The emergence of MDR MRSA infections is worrisome in the present therapeutic scenario, hence a continuous antibiotic surveillance is required for all the *Staphylococcus aureus* isolates. This inturn will help in formulation of effective antibiotic policies in the health care set-up or else the threat will increase.

In the present study 3% resistance was observed for Vancomycin by disc diffusion test, Harcharan Singh *et al*., (2013) conducted a study in Udaipur and observed a higher resistance of 13% to Vancomycin by using Disc diffusion method only. Similarly Yogesh Kumar Gupta *et al*., and Ankur Goyal *et al*., had reported no vancomycin resistance by Disc diffusion in Rajasthan and Agra respectively.

To conclude, the result of our present study indicated high antibiotic resistance to commonly used antibiotics by MRSA isolates. The increase in vancomycin resistance among MRSA and MDR- MRSA and excessive use of antimicrobial agents has worsened the sensitivity. Hence prudent and responsible usage of newer antibiotics is advocated to preserve their continued effectiveness in the management of difficult to treat infections caused by MRSA and VRSA. We should undertake more and more such studies in future to fight against rising menace of antibiotic resistance. Also more research should be done to find better treatment policies, effective and cheaper alternative antibiotics in developing countries like ours. The findings of the studies should be shared with hospital infection control committee to help in the formulation of infection control polices and also antibiotic policies. So that the primary care givers can use antibiotics rationally.

ABSTRACT

Backgrounds: *P. aeruginosa* is major causative organism of Nosocomial infections. The emergence of drug resistance and its transmission from patients to patients and from healthy persons to patients in ICU is major health concerns before the health workers in India. Moreover the accumulation of number of drug resistance genes in the this organism gives limited options for treatment of infections caused by it. Therefore, continued surveillance of drug resistance in this opportunistic pathogen is necessary to plan effective anti-microbial treatment against the infections caused by it.

Materials and Methods: From different clinical samples, *P.aeruginosa* was isolated and identified and tested for drug resistances on suitable media using standard procedures before the start and at the end of Stewardship Program. Statistical analysis was done using R statistical package in Linux system.

Results: All the drug tested for drug susceptibility testing show decreased in incidence of drug resistance after a one year time span. Gentamycin show highest decrease of 16.58% followed by ceftazidime at 13.92% and carbenacillin at 12.38%. whereas, the reduction in drug resistance to penicillin and and piperacillin is very low, i.e. only 1.19%.

Conclusions: Imipenem, with incidence of drug resistance of 4.13%, was found to be most effective drug and piperacillin and ciprofloxacin , both with incidence of drug resistance of 41.66% were least effective drug against P. aeruginosa in our study in the year 2016.

KEYWORDS : Antimicrobial Stewardship program, Nosocomial infections, Antimicrobial resistance, P. aeruginosa.

Introduction:

Pseudomonas aeruginosa, which is quintessentially ubiquitous opportunistic pathogen found in soil and water, causes number of post-operative and medical devices associated nosocomial infections in Indian hospital settings.

Spread of *Pseudomonas* infections through contaminated water is most common route of infection in hospital settings[1]. Lung infection of *Pseudomonas* is acquired by inhalation of aerosols of *Pseudomonas* contaminated water[1].

Moreover, due to high particulate pollution caused by soil dust, infections caused by Pseudomonas present in the dust is also high. Persons carry millions of dust particles and hence Pseudomonas present in them, which them easily transmit to inpatients.

The multi-drug resistance to number of routinely used anti-microbial drugs in this organism is matter of concerns among health workers in controlling and treating the infections caused by this organism, especially in hospital inpatients.

10% of the infections contracted during hospital stay of patients are caused by *Pseudomonas aeruginosa*[2].

Although the Pseudomonas infections are third leading causes of nosocomial infections that prolong the ICU stay, multi-drug resistance in this pathogen contributes to higher morbidity and mortality as compared to other pathogens in tertiary health care settings[3,4,5].

Number of studies in India have reported high prevalence of drug resistance in *Pseudomonas aeruginosa* isolated from various samples from 8.43% to 32.1%[6,7,8,9]

The higher drug resistance observed in *Pseudomonas aeruginosa* is due to presence of intrinsic drug resistance to number of drugs used against them, the selection pressure because of higher amount of antibiotics use inappropriately adds to the total drug resistance increasing incidence it many folds in this opportunistic pathogen.

To minimize the transmission of drug resistance and halt accumulation of drug resistance genes in *P. aeruginosa,* number of researchers suggested implementation of Stewardship programs[10]

One of the causes of emergence of drug resistance in bacteria, is higher selection pressure by use of higher amount of antibiotic inappropriately in hospital settings.

Stewardship program is defined as efforts of prescribing appropriate antimicrobial agents, its route, dosing and duration of its use in inpatient settings in order and reduce or prevent emergence of antimicrobial resistance, adverse consequences of its use, improve patients' health and provide cost effective therapy. Cochrane suggested one year period of the assessment of stewardship Programs on incidence of drug resistance in bacteria[10].

In the present study, researchers have studied the epidemiology of trends of drug resistance and incidence of infections caused by *Pseudomonas aeruginosa* with respect to the antimicrobial Stewardship programs for a period of one year.

Materials and Methods:

Sampling :

The number of clinical samples such as pus, urine, blood, sputum and body fluids were collected, as per standard procedures, from inpatients who developed infections after some kind of surgery or after some invasive medical procedures in order to investigate nosocomial infections, their causative organisms and incidence of drug resistance among them. The patients who have already have infections caused by *Pseudomonas aeruginosa* on admission to the hospital were excluded from this research study. Total 250 samples were processed for culture identification and drug susceptibility during each years of 2015 and 2016.

Culturing and identification of Pseudomonas isolates:

The isolates, for *Pseudomonas aeruginosa,* were cultured aerobically in Muller-Hinton broth for 16 to 24 hours at 37°C. The isolates were Gram stained and inoculated first into brain-heart infusion medium and then onto cetrimide agar. The Gram-negative bacteria from

isolated colony from cetrimide agar were confirmed as *Pseudomonas aeruginosa* by biochemical tests. The isolated were tested for oxidative fermentation and ability to grow at 42°C[11].

Implementation of Stewardship Program:
The above mentioned samples were microbiologically processed, drug susceptibility testing of isolated *Pseudomonas aeruginosa* was carried out in order to find out incidence of antibiotic resistance in this organism before the start and at the end ,after one year, of antimicrobial Stewardship program.

The antimicrobial Stewardship program was carried out between between January 2015 to December 2016 and continued thereafter also.

In the present Stewardship program, appropriate antimicrobial drug selection and its dosing was implemented. Antimicrobial therapy was started only after the culture identification and drug susceptibility testing were carried out. The antibiotic therapy was stopped as soon as a targeted infection is subsided.

Drug Susceptibility Testing:
Antibiotic susceptibility testing was carried out by Kirby-Bauer disk diffusion method as per CLSI guidelines[12,13] using antibiotics, gentamycin, piperacillin, carbenicillin, ciprofloxacin, amikacin, ceftazidime and imipenem.

Frequencies of drug resistance for each drug tested were recorded sample wise, gender wise and age group wise. Proportion and P-value was calculated using R-package of statistical analysis[14].

Results and discussion:
Results :
The total 250 various samples were selected randomly during January 2015 to December 2015, processed for drug resistance and data such as type of samples, type of infections and incidence of drug resistance was analyzed sample wise, gender wise and age-groups wise. Same procedure was followed for the 250 samples processed during January 2016 to December 2016. Sample-wise, gender-wise and age-groups wise incidences of nosocomial infections caused by *Pseudomonas aeruginosa* were recorded in **table No.1, 2** and **3** respectively.

Table No. 1 Sample-wise incidence of *Pseudomonas aeruginosa isolates* in 2015 and 2016 (sample size = 250)

Sr. No.	Specimen	Number of Samples in 2015	Number of Samples in 2016	proportions (%) in 2015	Proportions (%) in 2016
1	Wound Swab/Pus	20	14	57.14	58.33
2	Urine	10	5	28.57	20.83
3	Sputum	3	3	8.57	12.50
4	Body fluid	2	2	5.71	8.33
Total		35	24	100	100

Table No. 2 Gender-wise incidence of *Pseudomonas aeruginosa* infections in 2015 and 2016.

Sr. No.	Gender	Number in 2015	Number in 2016	Proportion(%) in 2015	Proportion(%) in 2016
1	Male	21	14	60	58.33
2	Female	14	10	40	41.66
Total		35	24	100	100

Table No. 3 Age-groups wise incidence of *Pseudomonas aeruginosa* infections in 2015 and 2016

Sr.No.	Age in years	No. of Patients in 2015	No. of patients in 2016	proportion (%) in 2015	Proportions (%) in 2016
1	0-21	3	2	8.57	8.33
2	21-40	5	8	14.28	33.33
3	41-60	17	12	48.57	50
4	61-80	10	2	28.57	8.33
Total		35	24	100	100

The data of incidence of drug resistance in *Pusedomonas aeruginosa* for year 2015 and 2016 was tabulated in **table No. 4.**

Table No. 4 Incidence of drug resistance in *Pseudomonas aeruginosa* isolates in 2015 and 2016 (Sample size = 250)

Sr. No.	Drugs (Mcg)	No. Of Sensitive Samples In 2015(%)	No. Of Sensitive Samples In 2016(%)	No. Of Resistant Samples In 2015(%)	No. Of Resistant Samples In 2016(%)	P-values
1	Gentamycin (10)	19(54.28)	17(70.83)	16(45.71)	7(29.13)	0.06391
2	Carbenicillin (100)	19(54.28)	16(66.66)	16(45.71)	8(33.33)	0.1516
3	Piperacillin (100)	20(57.14)	14(58.33)	15(42.85)	10(41.66)	0.5413
4	Amikacin (30)	20(57.14	16(66.66)	15(42.85)	8(33.33)	0.1516
5	Ciprofloxacin (5)	18(51.42)	14(58.33)	17(48.57)	10(41.66)	0.5413
6	Ceftazidime (30)	17(48.57)	15(62.5)	18(51.42)	9(37.50)	0.3075
7	Imipenem (10)	32(91.42)	23(95.83)	3(8.57)	1(4.13)	2.98e-06

Proportion of Wound and pus samples were remarkably high followed by urine samples both in years 2015 and 2016.

Male inpatients recorded higher incidence of pseudomonas infections than female patients both in the years 2015 and 2016.

The lowest resistance was observed for imipenem both for 2015 and 2016 of 8.57% and 4.13% respectively.

During the period of one year, all the drugs tested for drug susceptibility show remarkably high drug resistance.

Ceftazidime show highest resistance of 51.42%, followed by ciprofloxacin with resistance of 48.57%, in 2015 among all the drug tested whereas imipenem show lowest resistance of 8.57% in 2015.

In 2016, imipenem show lowest drug resistance of 4.13%, whereas other drugs show resistance between 29.13%(Gentamycin) to 41.66%(ciprofloxacin and piperacilin).

Discussion :
The incidence of Pseudomonas isolates and infections were 14% and 9.6% in the years, 2015 and 2016 respectively, sample-wise, gender-wise and age-group wise.

All the drugs tested for drug resistance, though show remarkably high resistance during 2015, the incidence of drug resistance has come down by 10% to 12% in 2016. During 2015, incidence of drug resistance for ceftazidime was 51.42% which observed to be 37.50% in 2016; thus incidence of drug resistance for this drug reduced by 16.58%. which is highest decrease in incidence of resistance. Penicillin, piperacillin show very negligible reduction of drug resistance, 1.19%, during a year period.

Incidence of drug resistance for Imipenem was recorded 8.57% in 2015 whereas it come down to 4.13% in 2016; a marginal reduction of 4.44%.

Thus the reduction in incidence of drug resistance is proportionate to initial incidence of the previous year, i.e. 2015; higher the incidence more is its down fall as results of various practices

followed in Stewardship program in this research work. However, the reduction in drug resistance to penicillin and and piperacillin is very low, i.e. only 1.19%, despite their remarkably high resistance in 2015; this might be due to presence of number of mutations governing a single drug resistance which take time to revert back to normal genes and this inferences can be supported by the facts that chromosomal β lactamase and MexAB-OprM MDR system are required for drug resistance to β lactam antibiotics[15]. This type of cooperative mutations show very low mutability rate in the organism[16] resulting in low decrease in incidence of drug resistance.

The high incidence of drug resistance among patients visiting this hospital might be because of accumulation of drug resistant strains of Pseudomonas aeruginosa among patients, most of who are living in dusty environment and frequently followed antibiotics regimes for acute respiratory system's illness; this inferences are drawn from oral communications by the patients since the history of such patients can not be recorded, which is the limitation of this research work.

Some significant outcomes of this research work are that that avoiding inappropriate use of anti-microbial drug, combination of more that one antibiotic use and implementation of good sanitary and aseptic practices in hospital environment help controlling spread of drug resistance in *Pseudomonas aeruginosa.*

Since the said hospital is situated in dusty environment and the dust being the major source of Pseudomonas infections, the researchers have suggested the air handling system to the administration of the hospital. The air handling system would provide microbe-free air to the modular operation theater, thus substantially reducing the microbial loan in the hospital air. The researchers, therefore, suggested to the said hospital administration to install pure air handling system in their hospital. The researchers also suggested to stop prescribing those antibiotics with high incidence of drug resistance, e.g. penicillin, piperacillin, ciprofloxacin and ceftazidime.

Conflicts of Interests:

The authors have no any kind of affiliations or financial involvement with any organization or department of government or private body with a financial interest in or conflict with the subject matter or materials discussed in the manuscript apart from those disclosed.

ABSTRACT

Background: *Pseudomonas aeruginosa* is a Gram negative, motile rod shaped bacterium. Production of different virulence factors make the *P.aeruginosa* more virulent. About 65% hospital acquired infections are associated with biofilms.

Objectives: To study incidence, antimicrobial susceptibility pattern and biofilm formation of *P.aeruginosa* clinical isolates.

Materials and Methods: Total 400 various clinical samples from different wards received for routine culture and sensitivity tests in the microbiology laboratory were processed during January 2015 to June 2015. Blood agar, MacConkey agar and nutrient agar plates were used for culture. Confirmed *P. aeruginosa* Isolates were screened for antimicrobial susceptibility pattern and biofilm formation. Muller-Hinton agar plates were used to study antimicrobial susceptibility pattern. Biofilm formation was studied by tube method.

Results: Total 6.25% (25/400) clinical samples were positive for *P.aeruginosa*. Out of 25, 18 (72%) isolates were from pus, 5/25(20%) urine and 2/25(8%) sputum. Twenty out of 25 (20/25, 80%) isolates were from male patients and 5/25 (20%) form female patients. Higher incidence was found in 41- 60 years of age group (19/25, 76%). *P.aeruginosa* found highly resistant to ceftazidime (48%) and 100% susceptible to imipenem. Fourteen out of 25 (14/25, 56%) isolates showed biofilm production and 11/15 (73.33%) MDR *P.aeruginosa* isolates showed biofilm production.

Conclusion: Most effective drug was Imipenem. Antibiotic resistance was higher among biofilm producers. This study showed strong association between biofilm formation and drug resistance.

Key words: *Pseudomonas aeruginosa*, Biofilm Formation, Imipenem.

INTRODUCTION

Pseudomonas aeruginosa *(P.aeruginosa)* is a gram negative, opportunistic pathogen. It causes acute and chronic infections.[1]

Moist sites in the hospital environment are known reservoirs of *P.aeruginosa* strains. They are often multidrug resistant due to intrinsic and acquired determinants.[2] It can survive with low levels of nutrients and grow in temperatures ranging from 4 – 42°C.[3]

P.aeruginosa is one of the members of normal flora of nasopharynx and is capable of colonizing the respiratory tract.[4]

Biofilm formation, development of drug resistance and production of different virulence factors make the *P.aeruginosa* more virulent.[5] It can cause Urinary tract infections, respiratory tract infections, dermatitis, soft tissue infections, bacteremia, bone and joint infections and gastrointestinal infections. They are more common in immunocompromised patients and in cystic fibrosis patients.[6]

Because of different metabolic and virulence properties, *P.aeruginosa* is capable of surviving in different environmental conditions.[7]

Biofilm production is an important determinant of pathogenicity in infections caused by *P.aeruginosa*. Biofilm presents strong resistance to the immune system and antibiotics. *P.aeruginosa* forms biofilm that contribute to acute, chronic and persistent infections.[8] *P.aeruginosa* is one of the main pathogenic organisms responsible for drug-resistant nosocomial infections and is becoming day-by-day very common pathogen. It may colonise healthy human without causing disease. Injudicious administration

of broad spectrum antibiotics, instrumentation and intrinsic resistance of microorganisms contribute to make *P.aeruginosa* a nosocomial pathogen.[9] Keeping these facts in mind, this study was undertaken to study the prevalence, antimicrobial susceptibility pattern and detection of biofilm formation among the *P.aeruginosa* clinical isolates.

AIMS AND OBJECTIVES

To determine prevalence, antimicrobial susceptibility pattern and to study biofilm formation of *P.aeruginosa* clinical isolates.

MATERIALS AND METHODS

This study was conducted at the Department of Microbiology in Dr. D. Y. Patil Medical College, Hospital and Research centre, Pimpri, Pune-411018. The study was conducted during January 2015 to June 2015.

Total 400 various clinical samples received from different wards of all ages and both sexes for routine culture and sensitivity tests were processed and confirmed *P.aeruginosa* isolates were screened for antimicrobial susceptibility pattern and biofilm formation.

Isolation and Identification of *P. aeruginosa*

All clinical samples were inoculated on Blood agar, MacConkey agar and Nutrient agar plates. The inoculated plates were incubated for 24 hours at 37°C. Isolates were confirmed as *P.aeruginosa* by colony morphology, grape like odour, pigment production (Figure-1), growth at 42°C, Gram staining, motility, and biochemical tests like catalase, oxidase, nitrate reduction test and citrate utilization tests.[10]

Antimicrobial Resistance Pattern

Antimicrobial resistance pattern was studied on Muller-Hinton (MH) agar by standard disc diffusion method (Kirby-Bauer) as recommended by Clinical and Laboratory Standards Institute.[11] Bacterial inoculum was prepared by using 16-24 hours old culture. Bacterial suspension was prepared using 4-5 isolated colonies. Standard inoculum size was prepared using turbidity standards (0.5 Mcfarland=$1.5x10^8$ CFU/ml) as a reference to adjust the turbidity of bacterial suspensions so that the number of bacteria will be within a given range.[12]

Bacterial suspension was inoculated on Muller-Hinton agar plates by using sterile swab on entire surface of agar plates. Antimicrobial agents used to study resistance pattern were amikacin (30µg), ceftazidime (30µg), ceftazidime/ clavulanicacid (30/10µg), ceftazidime/ tazobactum (30/10µg), carbenicillin (100µg), ciprofloxacin (5µg), gentamicin (10 µg), imipenem (10 µg) and piperacillin (100 µg).The antibiotic discs were placed on the surface of the inoculated plates and gently pressed with sterile forcep. Plates were incubated at 37°C for 18-24 hours. (Figure-2).

The diameter of inhibition zone was measured in millimetres and isolates were scored as sensitive or resistant by comparing with values recommended on standard charts.

Pseudomonas aeruginosa ATCC 27853 was used as the quality control organism in antimicrobial susceptibility determination.

Evaluation of Biofilm Formation by Tube Method

This is a qualitative method used for detection of biofilm formation. This test was carried out as described by Christensen et al.[13] A loopful of test organisms from overnight culture plates were inoculated in 10 ml of trypticase soy broth with 1% glucose in test tubes. Inoculated tubes were incubated at 37°C for 24hrs. Then tubes were decanted, washed with phosphate buffer saline (pH 7.3). Then tubes were dried and stained with crystal violet (0.1 %). Excess stain was removed and after washing with distilled water, tubes were dried in inverted position. Then dried tubes were observed for biofilm formation. A visible thick film lined the wall and the bottom of the tube was considered biofilm positive. The amount of biofilm formed was graded and recorded as a positive and negative biofilm formation (Figure -3A and 3B).

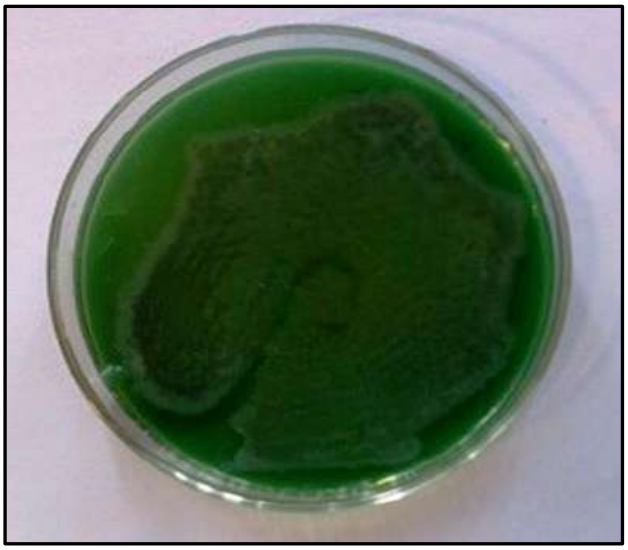

Figure 1: Growth of *P.aeruginosa* on nutrient agar.

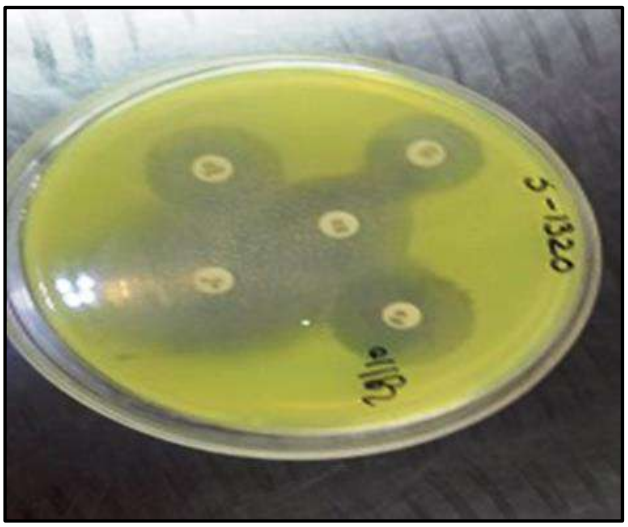

Figure 2: Antibiotic susceptibility test.

RESULTS

Out of 400 various clinical samples, 25 (6.25%) were positive for *P.aeruginosa.* Out of 25, 20 (80%) were from male patients and 5 (20%) were female patients (table 1).

Higher rate (19/25, 76%) of *P.aeruginosa* was found in 41-60 years of age group (table 2)

Out of 25 *P.aeruginosa* isolates, 18 (72%) were from pus followed by urine 5 (20%) and sputum 2 (8%) (table 3).

All Isolates were sensitive to imipenem (25/25, 100%) and antibiotic resistance was higher in ceftazidime (12/25, 48%). A total of 60% (15/25) *P. aeruginosa* were Multidrug resistance.

Out of total 25, 14 (56%) *P.aeruginosa* showed biofilm formation. Out of 15 MDRPA, 11 (73.33%) showed biofilm formation.

Age in years	n	%
0-20	01	04%
21-40	05	20%
41-60	19	76%
Total	25	100%

Table 3: Distribution of specimens of *P.aeruginosa* clinical isolates.

Specimen	n	%
Pus/wound swab	18	72%
Urine	05	20%
Sputum	02	8%
Total	25	100%

Table 4: Antimicrobial susceptibility pattern

Antibiotic	Sensitivity (%)	Resistance (%)
Amikacin (30mcg)	19 (76%)	6 (24%)
Ceftazidine + Clavulinic acid (30 + 10mcg)	16 (64%)	9 (36%
Ceftazidime + tazobactum (30 mcg + 10 mcg)	14 (56%)	11(44%)
Ceftazidime (30 mcg)	13 (52%)	12 (48%
Carbenicillin (100mcg)	14 (56%)	11 (44%)
Ciprofloxacin (5mcg)	17 (68%)	8 (32%)
Gentamicin (10mcg)	18 (72%)	7 (28%)
Imipenem (10mcg)	25 (100%)	0 (0%)
Piperacillin (100mcg)	16 (64%)	9 (36%)

DISCUSSION

The aim and objectives of this study were to determine prevalence, antimicrobial susceptibility pattern and to study biofilm formation of *P.aeruginosa* clinical isolates. The researcher processed total 400 various clinical samples received in Microbiology laboratory during January 2015 to June 2015.

Out of 400 clinical samples processed, 25 (6.25%) were positive for *P. aeruginosa.* In India, other researchers in similar studies have reported 2.76%, 8.2% prevalence of *P.aeruginosa* clinical isolate respectively.[14,15]

Prevalence of *P.aeruginosa* in pus was found to be 72 % (18/25) followed by 20% prevalence of the organism in urine. The higher prevalence (50.7%, 55.3%) of this pathogen in pus was also reported by other researchers respectively.[16,17]

The higher prevalence of *P.aeruginosa* isolates was observed in male patients (80%) than female (20%). Similarly, in other studies also the researchers reported the higher prevalence of *P.aeruginosa* in male than in female patients.[18] This shows that the male patients are more exposed to this pathogen than the female patients due to their occupational risks.

Higher prevalence of *P.aeruginosa* was found in 41-60 years age group (19/25, 76%) both in male and female patients. The other studies have also reported similar finding in India.[19]

P.aeruginosa clinical isolates were most sensitive to imipenem (100%) followed by Amikacin (76%) and least sensitive to ceftazidime (52%). These results are in agreement with other similar studies where researchers found that the pathogen was 90% sensitive to imipenem.[20] Thus imipenem is the most effective antibiotic and there is no resistance to this antibiotic; therefore this antibiotic should be used very judiciously so that least or no drug resistance develop in this pathogen. Out of 25 *P.aeruginosa* clinical isolates, 60% (15/25) showed MDR pattern. The higher MDR in this pathogen suggests that there is urgent need to implement the antibiotics stewardship program so that no further increase in the drug resistance appears in this pathogen. Further research is needed to find out the best antibiotic combinations to minimise the emergence and transmission of drug resistance in *P. aeruginosa.* In this study, 14/25 (56%) *P.aeruginosa* isolates showed biofilm production. This finding is in agreement with the 53.3%.[21] A total of 73.33% (11/15) MDR *P.aeruginosa* showed biofilm formation. The high proportion of biofilm markers among MDR *P.aeruginosa* strains suggest that the biofilm production play

some significant roles in showing drug resistant in agreement with same results shown in different studies.[22,23] This also suggests that there is strong association between biofilm formation and drug resistance. The association of biofilm production with MDR *P. aeruginosa* should be further investigated. Many times, the biofilm producing strains showing the drug resistance, clinically, is not true drug resistance but due to poor penetration of the drug in the biofilm showing the drug resistance in this pathogen.

CONCLUSION

Most effective drug was imipenem. Antibiotic resistance was higher among the biofilm forming strains of *P.aeruginosa*. Biofilm formation in MDR *P. aeruginosa* clinical isolate was recorded as 73.33%. This study showed strong association between biofilm formation and drug resistance. There should be continuous surveillance of drug susceptibility testing among *P. aeruginosa* strains in hospital setup. Further research is needed to find out the best antibiotic combinations to minimise the emergence and transmission of drug resistance in *P. aeruginosa.*

ETHICAL STATEMENT

The present study was approved by Institutional Ethical Committee of Dr. D. Y. Patil Medical College, Hospital and Research Center, Pimpri, Pune-411018.

Abstract:
Background: *Pseudomonas aeruginosa (P.aeruginosa) is an opportunistic pathogen and can infect almost all tissues. After multiplication and colonization, P.aeruginosa spreads within cells. Toxins and enzymes produced by P.aeruginosa are key factors that invade host cells and produce disease. P. aeruginosa harbours virulence genes like plcH, plcN, plcB, exoS, exoT, exoU, lasB, pilB, exoS, algD, nanI, pvdA. These virulent genes colonize the host cells and play important role in causation of disease. Phospholipases C involve in pathogenicity. P.aeruginosa produces two types of phospholipases C, haemolytic phospholipase C and non-haemolytic* phospholipase *C encoded by plcH and plcN genes respectively. Haemolytic phospholipase C is responsible for haemolysin production and show haemolytic activity. Phospholipases C are secreted via a micro machine known as Type -2 secretion system. Phosphate deficiency induces production of haemolytic phospholipase C. This study was focussed on study of detection of plcH gene and its and phenotypic expression in P.aeruginosa strains isolated from various clinical samples obtained at Tertiary Care Hospital.*
Objectives: *Detection of plcH gene and its phenotypic expression in P. aeruginosa isolated from various clinical samples received in a Tertiary Care Hospital.*
Materials and methods: *Thirty strains of P. aeruginosa isolated from clinical specimens were identified using standard laboratory methods. Gene plcH were detected by polymerase chain reactions and gel electrophoresis technique. Production of haemolysins was studied on 5% sheep blood agar plates.*
Results: *PCR amplification results showed presence of plcH genes in 22 (73.33%) out of 30 P.aeruginosa strains and 21 (70%) of the isolates showed haemolysin production.*
Conclusion*: Gene plcH of p. aeruginosa is one of the important virulent factors and plays key role in development of disease. It is concluded that plcH gene can be a striking pathogenic factor shown by presence of 73.33% and expressed phenotypically by 70% of P. aeruginosa strains isolated from clinical samples. The proved role of plcH virulent gene in the causation of disease would help in geeting clue of the prognosis of infections caused by Pseudomonas and scheming successful therapy and designing suitable vaccine against the prevention of infections caused by Pseudomonas.*
Key words: *P.aeruginosa, plcH, Haemolysin, PCR.*

Date of Submission: 20-12-2020 Date of Acceptance: 03-01-2021

I. Introduction

P. aeruginosa is Gram negative, motile, rod shaped opportunistic pathogen. It causes chronic and acute infections in human. Infections caused by *P. aeruginosa* play major role in cystic fibrosis, sepsis and in burn patients. Infections caused by *P. aeruginosa* are commonly observed in immune suppressed patients. [1-5].

A serious issue in infections caused by *P.aeruginosa* is multi-drug resistance to routinely used antibiotics to treat patients [6-7]. These high and multi-drug resistance is acquired due to genetic, intrinsic and acquired resistance [8]. *P.aeruginosa* is more virulent as it produces large number of cellular and extracellular virulence factors regulated by quorum sensing system. These virulence factors contribute in causation of disease in humans [9].

Virulence factors produced by *P.aeruginosa* play an important role in pathogenicity are exotoxins and exoenzyme U, exoenzyme S, exoenzyme T secreted by T3 secretion system encoded by *exoU, exoS* and *exoT* virulent genes respectively and elastage B encoded by *lasB. P.aeruginosa* produces haemolytic phospholipase C and non-haemolytic phospholipase C which are encoded by *plcH* and *plcN* virulence genes respectively. Phospholipid present in surfactans may be hydrolysed by phospholipases C [10-11].In India, very few researchers have worked on virulence factors like haemolytic phospholipase C and its allied *plcH* gene produced by *P. aeruginosa*. Considering these facts in mind, this research study was designed to detect and study the

distribution of *plcH* virulence gene and its phenotypic expression in *P. aeruginosa* isolated from various clinical samples obtained at Tertiary Care Hospital.

Aims and objectives: Aims and objectives were detection of *plcH* gene and its phenotypic expression in *P. aeruginosa* isolated from various clinical samples received in a Tertiary Care Hospital.

II. Materials And Methods:

This study was carried out at the Department of Microbiology, in Dr.D.Y.Patil Medical College, Hospital and Research Cenre, Pune-411018.

Various clinical samples like urine, sputum, pus, blood and body fluids, were received from different clinical wards including of all ages and both sexes for routine culture and sensitivity tests. All different clinical samples received were processed and confirmed strains of *P.aeruginosa* were screened for detection of *plcH* gene by Polymerase chain reactions technique and production of haemolysins was studied on 5% sheep blood agar plates.

Ethical statement

This research study was approved by Institutional Ethical Committee of Dr.D.Y.Patil Medical College, Hospital and Research Centre (Dr.D.Y.Patil Vidyapeeth), Pune.

Source of Funding: None.

Coflict of Interest: None.

Isolation and Identification of *P.aeruginosa*

All different clinical samples received were inoculated onto nutrient agar, blood agar and MacConkey agar plates. After inoculation and incubation 37ºC for 24 hrs, plates were examined for presence of growth. *P.aeruginosa* was confirmed by studying colony morphology, pyocyanin pigments production, typical grape like odour, tendency to growth at 42ºC, Gram staining, motility test, positive citrate and oxidase tests [12].

Detection of haemolysin production of *P.aeruginosa* isolated from various clinical samples

Detection of Hemolysins: All 30 strains of *P.* aeruginosa isolated from various clinical samples under this study were screened for detection of haemolysin production activity. *P.aeruginosa* grown for 18 hours at 37ºC in nutrient broth were plated on blood agar containing 5% (vol/vol) sheep blood to obtain isolated colonies. Plates were incubated at 37ºC for 24 hours. The clear zone around the colonies (total lysis of red blood cells around the colonies) was considered as positive reaction for production of haemolysins [13, 14].

Detection of *plcH* gene of *P.aeruginosa* isolated from various clinical samples

Extraction of DNA:

For the screening of *plcH* virulence genes of *P.aeruginisa,* Chromosomal DNA from the 30 clinical strains of *P.aeruginosa* clinical isolates under this study was extracted. Purification of extracted DNA was carried out using (Ganeaid-Presto™ Mini gDNA bacteria Kit) a commercial available DNA extraction kit following the manufacturer's guidelines.

Polymerase Chain Reaction: The sequences of the primers used in polymerase chain reactions for detection of *plcH* gene and its molecular weight are shown in Table No.1.

Table No.1: The Primer sequence used for the screening of *plcH* genes.

Gene	Primer sequence	Amplicon size	Length(bp)	References
plcH	Forward 5'-GAAGCCATGGGCTACTTCAA-3' Reverse 5'-AGAGTGACGAGGAGCGGTAG-3'	20 20	307	15, 16

The chromosomal DNAs extracted from *P.aeruginosa* strains under study were used as templates for polymerase chain reactions. Polymerase chain reactions were carried out in 25ul mixture containing 7.5ul distilled water, 1.5ul forward primers, 1.5ul reverse primers, 2.0ul DNA template and 12.5ul mastermix (Geneaid-Presto™Mini gDNA bacteria Kit).

The Polymerase chain reactions were carried out using conditions as shown in Table No.2

Table 2: Conditions used for Polymerase Chain Reactions.

Gene	Initial denaturation	No.of Cycles	Denaturation in each cycle	Annealing	Primer extention	Final extention
plcH	95ºC, 2 min	30	95ºC, 30 sec	55ºC,30 sec	72ºC, 30 sec	72ºC,5 min

Gel electrophoresis

Polemerase chain reaction products of *P.aeruginosa* were used for gel electrophoresis. For a gel preparation, 250 ml agarose quantity was required. Agarose gel was prepared with 2% agarose and ethidium bromide as it shows good resolution for small fragments. Images of PCR products were detected using transillumator by UV illumination as shown in image No.1. For the estimation and to compare size of PCR products, the 100bp DNA molecular size markers were used [17].

III. Results:

This research study was carried out using 30 strains of *P.aeruginosa* isolated from various clinical samples in respect to sites of infections as shown in Table No.3

Image No.1: Images of Gel Electrophoresis and amplification Products of *plcH* virulence genes of *P.aeruginosa*.

IV. Discussion

The aims and objectives of this research were to detect *plcH* virulence gene and its phenotypic expression in *P.aeruginosa* isolated from different clinical samples. In this research study, 30 strains of *P.aeruginosa* clinical isolates were included.

P.aeruginosa possesses number of quarum sensing genes which encode for number of exotoxins and exoenzymes. These exotoxins and exoenzymes are virulence factors playing their active roles in pathogenicity of various infections caused by the organism.

There are total 23 so far known bacterial virulence genes, namely *lasl, lasB, lasA, lasR, rhlR, rhIl, rhlAB, fliC, aprA, plcN, plcH, toxA, ExoT, ExoS, ExoY, ExoU, phzI, phzll, phzS, phzM, pilA, pilB* and *pvdA* [18].

The present paper discuss only the *plcH gene* encoding for haemolysin proteins. *plcH* is an important virulence genes encoding for haemolytic phospholipase C. Hemolytic phospholipase C play an important role in spreading type of infections caused by *P.aeruginosa*. Finding out its prevalence is important, as an epidemiological marker in pathogenic *P.aeruginosa.*

In this study, out of 30, 22 (73.33%) *P.aeruginosa* clinical strains were positive for *plcH* gene. This finding is in agreement with similar studies where the prevalence of *plcH* was documented as 70.42% and 75% respectively [19, 20]. Other researchers have reported high incidence of *plcH* gene in *P.aeruginosa* strains isolated from different clinical specimen in hospitals [21, 22, 23]. In pus samples, 66.66% isolates showed presence of *plcH* gene and 80% *P.aeruginosa* strains obtained from urine samples were positive for *plcH* gene. All *P.aeruginosa* strains were positive for *plcH* gene isolated from blood and sputum. Therefore, detection of *plcH* gene can be conveniently used as one of the important markers of virulence in epidemiological study.

The presence of *plcH* and its encoded product determine the prognosis of infections caused by *P. aeruginosa* and also predict the possibility of development of spreading type of infections. In the present study, 70% (21/30) of *P.aeruginosa* clinical isolates showed haemolysin production.Haemolysin production was found highest (100%) in blood and sputum isolates showing expression of *plcH* gene and suggesting that the haemolysin virulence factor is highest in spreading and systemic type of infections caused by *P. aeruginosa*. In other research studies showed that in majority of infections caused by *P.aeruginosa*, the *plcH* and its phenotypic expression were reported at 100 proportion [24, 25]. Such spreading type infections caused by *plcH gene* possessing strains of the organism had high morbidity and were more difficult to treat. The multi-drug resistance in such strains further aggravate infections resulting in high morbidity and mortality. Researchers, therefore suggest that the *Pseudomonas aeruginosa* clinical isolates having *plcH* gene, must always to subject to drug susceptibility testing in order to manage the infections effectively.

Statistical analysis:

By using Fisher exact test, the 'P' value is 0.00001. As the $P < 0.05$, result is significant and hence, there is strong association between *plcH* genes and its phenotypic expression.

Therefore either the detection of presence of *plcH* gene or its phenotypic expression can be used to determine the development and prognosis of spreading type of infections caused by *P. aeruginosa.*

V. Conclusion

We found that majority of the *P.aeruginosa* strains isolated from patients having spreading type of infections possessed *plcH* gene and its corresponding phenotypes.

We also found that since there is strong correlation between the presence of *plcH* gene and its phenotypic expression ($P<0.05$); either of the in-vitro detection of *plcH* gene or its phenotypic expression can be used to determine the severity and prognosis of pseudomonas infections in patients.

The *plcH* gene detection by polymerase chain reaction is rapid method than the detection of its phenotypic expression and therefore would be more helpful in epidemiological study and in deciding the treatment course for the infections caused by *P. aeruginosa.*

ABSTRACT

Background: Since there is a significant rise in resistant bacteria to different antimicrobial agents, there is a need to study the resistance pattern of different isolates from different clinical samples for effective use of available antimicrobials by clinicians. The aim of the present study was to detect the resistance pattern of various antimicrobials against different clinical isolates in hospitalised patients in out setting.
Methods: This is a retrospective study involving the collection of the data from the records of microbiology laboratory. All clinical specimens were processed as per standard microbiological procedures. Antibiotic susceptibility testing was performed by Kirby Bauer disc diffusion method on Mueller Hinton agar plate as per CLSI guidelines.
Results: A total of 153 isolates were recovered from 219 clinical samples accounting for 69.86% of total positivity. Which includes gram negative bacilli 107/153 (69.93%) gram positive cocci 36/153 (23.53%) and yeast 10/153 (6.54%). Among the total isolates gram negative bacilli account for major number of isolates 69.93% followed by gram positive cocci 23.53% and yeast 6.54%. Gram positive cocci and gram-negative bacilli showed a significant level of antimicrobial resistance. Nitrofurantoin is highly effective against urinary isolates of *Escherichia coli.* vancomycin and linezolid are most effective antimicrobials against gram positive cocci. Among gram negative bacilli meropenem and amikacin are most effective antimicrobials. Statistical significance of occurrence of *Escherichia coli* as predominant isolate as compared to other isolates were analysed by chi square test by using GraphPad online calculator. A p value<0.001 was obtained.
Conclusions: Significant rise in antimicrobial resistant pathogens were observed. Local antimicrobial policy should be developed for effective selection of available antimicrobials which are the need of the day to reduce the burden of diseases on global health care system.

Keywords: Antimicrobial resistance, Gram negative bacilli, Gram positive cocci

INTRODUCTION

Infections with microbes has a drastic effect on human health.[1] Microbial infections are important cause of morbidity and mortality across the globe with increase resistance of pathogens to different antimicrobial agents posing great concern to public health.[2] Antimicrobials are being used to overcome the drastic effect of microbial agents. Their wide spread use has led to emergence of multidrug resistant (MDR) pathogens. Antimicrobial resistance (AMR) may be due to natural, acquired/clinical resistance.[1]

High morbidity and mortality are seen in infections caused by drug resistant pathogens. The pattern of resistance to various antimicrobial agents may change over a period of time.[3] Nosocomial infections pose a great challenge to the well fare of the patient

management, since most of them are MDR strains. This increases the hospital stay of in patients and increases the health care cost.[1]

AMR is a great health care problem in India.[4] The burden of infectious disease is more in India because of increased drug resistant bacteria due to indiscriminate use of antimicrobials. Frequent cause of hospitalisation is associated with different microbial infections. The choice of selecting an effective antimicrobial agent has been reduced because of their resistance to different pathogens causing hospital and community acquired infections.[5]

Patients infected with drug resistant pathogens are at high risk of serious clinical outcomes and require more heath care services. Resistance to different antimicrobials is seen because of indiscriminate use of different antimicrobial agents, which in turn leads to mutations and results in drug resistance. MDR bacteria pose great threat for patients. since, it becomes very difficult to treat such patients and requires use of broad-spectrum antibiotics.[6]

METHODS

This was a retrospective study which involves analysis of medical microbiology test results of different clinical samples collected over a period of 6 months between July 2019 to December 2019. Only IPD patients were included in the study. The study was carried out at Ananta Institute of Medical sciences and research center, Rajsamand. This is a tertiary care hospital.

Data collection and testing

Type of clinical samples, isolates, age, sex and their antimicrobial susceptibility pattern were collected from the records. All clinical specimens were processed as per standard microbiological procedures. The isolates were first identified by standard biochemical techniques and then subjected to antibiotic susceptibility testing by Kirby Bauer disc diffusion method on Mueller Hinton agar plate as per CLSI guidelines.[5]

Antibiotic discs

The following antibiotic discs containing amikacin AK 30 mcg, amoxycillin/clavulanic acid AMC 30 mcg, ampicillin/sulbactam A/S 10/10 mcg, azithromycin AZM 15 mcg, aztreonam AT 30 mcg, cefoxitin CX 30 mcg, ceftizoxime CZX 30 mcg, ceftriaxone CTR 30 mcg, cefuroxime CXM 30 mcg, ciprofloxacin CIP 5 mcg, clindamycin CD 2 mcg, colistin CL 10 mcg, erythromycin E 15 mcg, gentamicin GEN 10 mcg, imipenem IPM 10 mcg, levofloxacin LE 5 mcg, linezolid LZ 30 mcg, meropenem MRP 10 mcg, piperacillin/ tazobactum PIT 100/10 mcg, polymyxin-B PB 300 units, trimethoprim TR 5 mcg, vancomycin VA 30 mcg, cefoperazone/ sulbactam CFS 75/10 mcg, ceftazidime/clavulanic acid CAC 30/10 mcg, nitrofurantoin NIT 300 mcg were used as per manufacturer (Himedia) instructions.

Statistical analysis

Statistical analysis was done by using GraphPad online calculator. Chi square test was employed. P value<0.05 is considered as statistically significant

RESULTS

A total of 153 isolates were recovered from 219 clinical samples accounting for 69.86% of total positivity. Which includes gram negative bacilli 107/153 (69.93%) gram positive cocci 36/153 (23.53%) and yeast 10/153 (6.54%). Among the total isolates gram negative bacilli account for major number of isolates 69.93% followed by gram positive cocci 23.53% and yeast 6.54% (Table 1).

Among the gram-negative bacilli, the major isolates are *Escherichia coli* 35.29% followed by *Klebsiella* species 12.41% and *Pseudomonas aeruginosa* 12.41%. Among the gram-positive cocci, the major isolates are coagulase negative *Staphylococcal species* (CONS) 12.41% followed by coagulase positive *Staphylococcus* (*Staphylococcus aureus*) 6.53% and *Enterococcus faecalis* 4.57%. Among the yeast the major isolate is *Candida albicans* 4.57% followed by *Candida tropicalis* 1.96% (Antifungal agents were not tested).

Among different clinical samples received urine samples account for highest number of isolates 62/119 (52.10%). Among which gram-negative bacilli accounts for 53/62 (85.48%) followed by gram positive cocci 5/62 (08.06%) and yeast 4/62 (06.45%). *Acinetobacter* species were predominant in clinical aspirates 10/21 (47.61%). *Pseudomonas aeruginosa* was predominant in pus 11/48 (22.91%) (Table 1). A total of 10 co-infections were detected among the total isolates (Table 1).

Antimicrobial resistance

Antimicrobial resistance pattern of gram-negative bacilli and gram-positive cocci varied from nil to 100% for different isolates. The details of each isolate and their antimicrobial resistance pattern is given in Table 2 and 3.

Among gram negative isolates, meropenem and amikacin are more effective against *E-coli* with 9.25% and 18.51% resistance respectively each. Meropenem and piperacillin/ tazobactam are more effective against *Klebsiella* species with 36.84% and 47.36% resistance respectively each. Amikacin and ciprofloxacin are more effective against *P. aeruginosa* with 15.78% and 31.57% resistance respectively each. Amikacin, ampicillin/sulbactam and levofloxacin are more effective against *Acinetobacter* species with 41.66% resistance respectively each. Polymyxine-B and colistin showed no resistance when used against *P. aeruginosa* and *Acinetobacter* species. Piperacillin/ tazobactam is more effective against proteus species with 33.33% resistance (Table 2).

Among gram positive isolates ampicillin/sulbactam, cefoxitin/clindamycin are more effective against cons with 21.05% and 26.31% resistance respectively each. Clindamycin and trimethoprin/ sulphamethoxazole are more effective against *S. aureus* with 30% and 60% resistance respectively each. Gentamicin and Trimethoprin/ sulphamethoxazole more effective against *Enterococcus faecalis* with 14.28% and 57.14% resistance respectively each. Gentamicin is nil resistant to CONS and *S. aureus*. Linezolid and vancomycin are nil resistant to *Enterococcus faecalis*, CONS and *S. aureus* (Table 3). Among total number of clinical isolates, males accounted for (54.25%) positivity and females accounted for (45.75%) positivity. Among the male patients the predominant isolates are *E-coli* (30.12%), followed by *P. aeruginosa* (16.86%) and *Acinetobacter species* (14.45%). Among the female patients the predominant isolates are *E-coli* (41.42%), CONS (15.71%) and *Klebsiella* species (12.85%). Details of each isolate in males and females are mentioned in Table 4.

Statistical significance of occurrence of *Escherichia coli* as predominant isolate as compared to other isolates were analysed by chi square test by using GraphPad online calculator. A p value<0.001 was obtained.

DISCUSSION

Different pathogens are associated with human infections. Management of this infectious diseases by timely identification and selection of effective antimicrobials against the causative agents help in early recovery of the patients and also helps in reducing the hospital costs as well as the stay time in hospital. Emergence and spread of MDR pathogens are a major challenge for better health care management. MDR pathogens increase morbidity and mortality in hospitalised patients. This study present various pathogens isolated from different clinical samples and their antimicrobial activity in hospitalised patients.

The total positivity of the clinical isolates of the present study were 69.86% with predominance of gram-negative bacilli 69.93% as compared to gram positive cocci 23.53%. An earlier study has reported a total positivity of 64.70% which correlates with our study.[7] Abebe et al and Masyeni et al reported gram-negative bacilli as the most predominant isolate. Similar findings are observed in the present study. Most of the nosocomial infections are associated with gram negative bacilli causing severe form of the disease. These strains are mostly MDR.[3,8]

The present study has reported a high-level resistance to various class of antimicrobials against gram negative bacilli and gram-positive cocci. Antibiotic resistance is a threat to the world and is a major public problem in India. since, India harbours great burden of bacterial diseases. Emergence of MDR strains from India for gram negative bacilli and gram-positive cocci has been reported.[9] This coincides with the present study which shows high resistance of bacteria to various antimicrobials.

Urine samples accounted for majority (54.33%) of the samples in the present study. similar findings have been observed with other studies.[1,5] The most common pathogen isolated from all clinical samples in our study was *Escherichia coli* 35.29% with predominance of females (57.05%) as compared to males (42.95%). This is followed by *Klebsiella* species, CONS and *Pseudomonas aeruginosa* 12.41% each. These findings are in correlation with other studies.[2,9,10] Among the uropathogens isolated, *Escherichia coli* and *Klebsiella* species were the predominant isolates in our study which correlates with earlier studies.[5,12]

Among the antimicrobials used against *Escherichia coli*, meropenem showed 09.25% resistance, amikacin showed 18.51% resistance and piperacillin/ tazobactam showed 29.62% resistance. Nitrofurantoin showed nil resistance against *Escherichia coli* isolates from urine. similar findings were also reported by other studies with decreased potency of ciprofloxacin and co-trimoxazole among uropathogens.[5,6,10] Among *Klebsiella* species isolated meropenem is more effective which showed 36.84% resistance. This finding is different from an earlier study which reported 100% resistance.[4] In *Pseudomonas aeruginosa* nil resistance was observed for polymyxine-B and colistin. Amikacin showed least resistance 15.78% to *Pseudomonas aeruginosa* followed by meropenem 26.31%. Higher rate of resistance for amikacin (78.00%) and meropenem (100.00%) was reported by an earlier study.[4] *Acinetobacter* species showed nil resistance to polymyxine-B and colistin and 41.66% resistance to amikacin, ampicillin/ sulbactam and levofloxacin respectively each. Piperacillin/tazobactam was the most effective antimicrobial against proteus species with 33.33% resistance. This finding is different from a previous study which reported 100.00% resistance to piperacillin/ tazobactam.[4]

Among the gram-positive isolates nil resistance was observed for vancomycin, linezolid. Gentamicin showed nil resistance against CONS and *Staphylococcus aureus* but showed 14.28% resistance against *Enterococcus faecalis*. Among CONS, ampicillin/sulbactam was the most effective antimicrobial with a resistance of 21.05% followed by cefoxitin and clindamycin with 26.31% resistance. This finding is different from an earlier study which reported 100% sensitivity to cefoxitin and clindamycin.[5] *Staphylococcus aureus* showed least resistance to clindamycin (30%). This finding is different from an earlier study which reported 100% resistance to Clindamycin.[5] Trimethoprin/ sulphamethoxazole showed a least resistance of 57.14% when used against *Enterococcus faecalis*. Khatun et al reported a higher resistance of 75% to trimethoprin/ sulphamethoxazole. The difference in the resistance pattern of different antimicrobials for gram negative bacilli and gram-positive cocci in different studies may be attributed to the usage of that particular antimicrobial in different settings.

High rate of resistance to various antimicrobials in our study may be due to inclusion of only hospitalised patients. Since nosocomial infections are seen in hospitalised patients and the strains are generally resistant to most of the commonly used antimicrobials. Similar findings were observed by earlier studies which included IPD and OPD patients.[5,6] The high rate of antimicrobial

resistance in IPD patients may indicated the need for surveillance studies on nosocomial infections to identify the source of infection. Incorrect diagnosis may lead to irrational use of antibiotics which may lead to overuse or misuse of antimicrobials resulting in dissemination of antibiotic resistance.

CONCLUSION

The most predominant isolate from different clinical samples in our study was *Escherichia coli*. Among gram negative isolates in the present study, the most effective antimicrobials are colistin, meropenem, amikacin, piperacillin/tazobactam, ampicillin/ sulbactum. Among urinary isolates of *Escherichia coli*, nitrofurantoin is very effective. Gentamicin, vancomycin and linezolid are most effective antimicrobials against gram positive cocci in our study. Significant rise in resistance to antimicrobials was observed in this study. Local antimicrobial policy should be developed for effective selection of available antimicrobials which are the need of the day to reduce the burden of diseases on global health care system.

Prevalence of *exoT* Gene in *Pseudomonas aeruginosa* Isolated from Various Clinical Samples: A Cross-sectional Study

JAGANNATH DNYANOBA ANDHALE[1], M ANJANEYA SWAMY[2], RN MISRA[3]

ABSTRACT

Introduction: *Pseudomonas aeruginosa (P.aeruginosa)* is one of the most frequently co-infecting bacteria reported. Development of drug resistance, biofilm formation, cell associated factors make the *P.aeruginosa* more virulent. Type III secretion system controls expression of genes. *P.aeruginosa* chromosome harbours *exoT, exoS, exoU*, and *exoY* virulent genes. Gene *exoT* plays an important role in causation of infection. The identification of virulent markers of pathogens for identification of acute and chronic infections at early stage remains a critical area and still need large research.

Aim: To study the prevalence of *exoT* gene encoding exotoxin T in *P.aeruginosa* from clinical samples.

Materials and Methods: A descriptive cross-sectional research was conducted during January 2015 to March 2016 at the Department of Microbiology in Dr. D.Y. Patil Medical College, Pimpri, Pune, Maharashtra, India. Various clinical samples were processed using standard laboratory methods. The statistical analysis was done by using Chi-square test. Strains of *P.aeruginosa* isolated from various clinical samples were identified using standard laboratory methods, and *exoT* gene was detected by Polymerase Chain Reaction (PCR) and gel electrophoresis technique.

Results: Out of 30 strains of *P. aeruginosa*, 20 (66.67%) were isolated from male and 10 (33.33%) from female patients. Most of them belonged to the age group 41-60 years (46.67%). The *exoT* gene occurred in 20/30 (66.67%) isolates of *P.aeruginosa*, while 10/30 (33.33 %) showed negative amplification results. Out of 20 *exoT* genes in *P.aeruginosa*, 17/20 (85%) were detected from male and 3/10 (15%) from female patients.

Conclusion: Gene *exoT* of *P. aeruginosa* plays the crucial role in causation of disease. It is concluded that *exoT* gene can be a notable virulent element expressed by 66.67% of *P.aeruginosa* clinical isolates. The proven role of *exoT* virulence gene in the pathogenicity of *P.aeruginosa* would help in understanding the prognosis of *Pseudomonas* infection and designing an effective treatment and vaccine against the *Pseudomonas* infections to prevent them.

Keywords: Exotoxin T, Gram negative bacteria, Polymerase chain reaction

INTRODUCTION

Pseudomonas aeruginosa (*P.aeruginosa*) is an actively motile, biofilm forming Gram negative human opportunistic pathogen. It exhibits multidrug resistance and is widely connected with hospital acquired infections [1]. They are resistant to multiple antibiotics due to acquired or inherent determinants. It can cause acute and chronic infections [2]. *P.aeruginosa* causes serious infections such as endocarditis, pneumonia, septicaemia, wound infections, cystitis [3], blood stream infections, urinary tract infection and surgical site infections [4]. Biofilm formation, development of drug resistance, various secreted toxins, proteases, pyocyanin, exotoxins and different cell associated factors make *P.aeruginosa* more virulent [5]. *P.aeruginosa* has the ability to colonise the respiratory tract and is one of the members of normal flora of nasopharynx [6]. *P.aeruginosa* infections are more frequently observed in cystic fibrosis and in weakened immune patients. In a recent study, researcher documented *P.aeruginosa* as a common co-infecting pathogen in patients [7].

P.aeruginosa continues to exist in different environmental states because of different virulence factors and metabolic properties [8]. Toxins are released by passive transport from the cells secreted by one of the three secretion systems namely, Type I Secretion System (T1SS), Type II Secretion System (T2SS) and Type III Secretion System (T3SS). Type III secretary system plays a key role in determining virulence [9]. The Gram negative bacteria have a complex T3SS which is an essential machinery of *P.aeruginosa* to inject exotoxin T (*exoT*), exotoxin S (*exoS*) and exotoxin U (*exoU*) virulence factors directly into host cells [10] and can evoke different responses from the host suitable for spreading of infection [11]. Exotoxin produced during release and escape of pathogen mainly attacks host kinases and is responsible for adhesion, phagocytosis, with spreading type of infection from lung to the liver in experimental animal [9,12].

Very few researchers in India have focussed on *exoT* gene encoding exotoxin T, virulence factor of T3SS of *P.aeruginosa*. In previous similar study in India, the researcher documented 84% prevalence of *exoT* gene in *P.aeruginosa* strains obtained from various clinical samples [13]. Keeping these facts in mind, this study was designed to study the prevalence of *exoT* gene in *P.aeruginosa* obtained from different clinical samples in a tertiary care hospital.

MATERIALS AND METHODS

Present descriptive cross-sectional research was conducted during January 2015 to March 2016 at the Department of Microbiology in Dr DY Patil Medical College, Hospital and Research Centre, Pimpri, Pune, Maharashtra, India. Different clinical samples (pus, urine, sputum, blood and body fluids) were received from various wards irrespective of age and gender for routine culture and sensitivity tests. The isolates were processed and confirmed *P.aeruginosa* strains were screened for detection of *exoT* gene by PCR and gel electrophoresis techniques. The study was done after approval from Institutional Ethical Committee of Dr DY Patil Medical College, Hospital and Research Centre, Pimpri, Pune, Maharashtra, India.

Inclusion criteria: Samples showing *P.aeruginosa* as single causative agent of infection were included in this study. Total 30 strains were included in this research study.

Exclusion criteria: Samples showing mixed growth were excluded from this study.

Isolation and identification of *P.aeruginosa*: All clinical samples were inoculated onto MacConkey agar, Nutrient agar and Blood agar plates. Inoculated plates were incubated at 37ºC for 24 hours. After obtaining the growth, *P.aeruginosa* was identified by studying colony characteristics, production of pyocyanin pigments, grape like odour, growth at 42ºC, motility test, Gram staining, and positive oxidase, citrate, and catalase tests [14].

Extraction of DNA: For the detection of *exoT* gene, chromosomal DNA from the 30 clinical strains of *P.aeruginosa* clinical isolates was extracted and DNA purification was carried out using a commercial available DNA extraction kit (Ganeaid-Presto™ Mini gDNA bacteria Kit) as indicated by manufacturer's instructions.

Polymerase Chain Reaction (PCR): The sequences of the primers used in PCR for detection of *exoT* gene and its molecular weight are shown in [Table/Fig-1] [15,16].

Gene	Primer sequence	Amplicon size	Length (bp)
exoT	Forward 5'-AATCGCCGTCCAACTGCATGCG-3'	22	152
	Reverse 5'-TGTTCGCCGAGGTACTGCTC-3'	20	

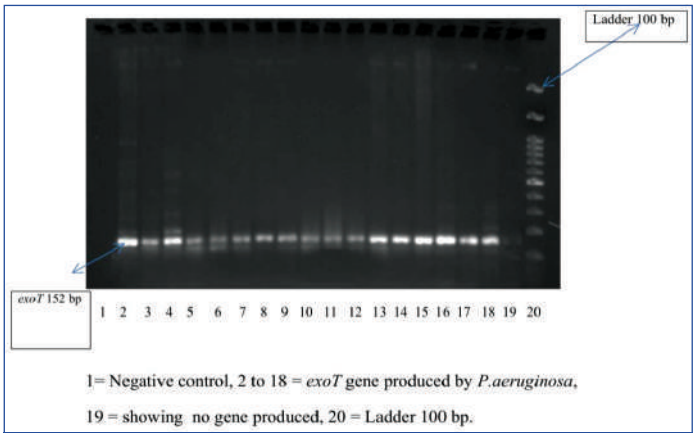
[Table/Fig-1]: The Primer sequence used for the detection of exoT genes.

For all PCRs, the DNA extracted from *P.aeruginosa* under study was used as templates. PCRs were carried out in 25 µL mixture containing 12.5 µL mastermix (Geneaid-Presto™Mini gDNA bacteria Kit), 1.5 µL forward primers, 1.5 µL reverse primers, 2.0 µL DNA template and 7.5 µL distilled water [Table/Fig-2].

Gene	Initial De-naturation	No.of Cycles	Denaturation in Each Cycle	Anneal-ing	Primer Extention	Final Extention
exoT	95ºC, 2 min	36	95ºC, 30 sec	58ºC,30 sec	72ºC, 30 sec	72ºC,5 min

[Table/Fig-2]: Polymerase Chain Reaction (PCR) conditions.

Gel electrophoresis: Electrophoresis was done using PCR products of *P.aeruginosa*.To prepare agarose gel, 2% agarose with ethidium bromide was used, as it shows clear resolution for small fragments. The quantity of agarose used for a gel preparation was around 250 mL. Images of PCR products were detected using transillumator by UV illumination is shown [Table/Fig-3]. PCR products were estimated by comparing with the 100bp DNA molecular size markers [17].



[Table/Fig-3]: Showing gel electrophoresis and amplification products of virulence gene (*exoT*) of *Pseudomonas aeruginosa* clinical isolates.

STATISTICAL ANALYSIS

The statistical analysis was done by using Chi-square test on line by graphpad prism 9.2.0.332. The calculated p-value was 0.0093 which is significant.

RESULTS

Out of 30 strains of *P.aeruginosa*, 20 (66.67%) were isolated from male and 10 (33.33%) from female patients. Most of the subjects belonged to 41-60 years of age group (46.67%). Out of 20 *exoT* genes in *P.aeruginosa*, 17/20 (85%) were detected from male and 3/10 (15%) from female patients [Table/Fig-4].

Age group (years)	Male	Female
0-20	00	00
21-40	02	01
41-60	12	02
61-80	03	00
Total	17	03

[Table/Fig-4]: Age and gender wise distribution of prevalence of *exoT* gene in *P.aeruginosa* (N=20).
Chi square 6.769, df-1, p-value=0.0093, p-value is statistically significant

The prevalence of *exoT* gene was 66.67%. Out of 30 strains of *P.aeruginosa* clinical isolates, 20 (66.67%) showed amplification of *exoT* gene and 10 (33.33%) strains showed negative amplification [Table/Fig-5].

DISCUSSION

P.aeruginosa is one of the major and well identified nosocomial pathogen. It has capability to survive and multiply with minimal nutrients. It can cause severe infection in hospitalised patients. *P.aeruginosa* is one of the most common co-infecting pathogen and exotoxin T is virulence factor that make *P.aeruginosa* more virulent for host cells. This descriptive research study was undertaken to detect *exoT* gene encoding exotoxin T in *P.aeruginosa* clinical isolates. T3SS is a basic and important weapon of *P.aeruginosa* and several other Gram negative

organisms for survival and causation of disease. The T3SS is a needle like sharp tiny machine that carry and deliver effector proteins (exotoxins) directly into targeted cells of the host to start disease. These delivered exotoxin precipitate and continue progress of infection by changing normal functions of target cells, such as constant movement of network of protein filaments and microtubules in the cytoplasm, reactions of cells to inflammatory stimuli, signalling pathways and secretory trafficking [18]. T3SS complex cellular nano machine is a key weapon of several pathogenic Gram negative bacteria which works in a systematic planned mode of action and can alter the target cell in number in irregular manner. T3SS has gradually developed because of the pressure of the survival within infected cells.

Virulence factors injected by T3SS into host cells play important role for *P.aeruginosa* to be more virulent [19,20]. The gene *exoT*, modify the actin cytoskeleton, inhibit migration and multiplication of cell. Exotoxin T prevents adhesion, phagocytosis, excessive multiplication and stop epithelial barrier that help *P.aeruginosa* to cause spread type of infections [21]. Gene *exoT* is an important virulence gene encoding exoenzyme T. Therefore, detection of *exoT* gene is important while determining pathogenicity of *P.aeruginosa* in different type of infections.

In this research study, authors aimed to determine the prevalence of *exoT* virulent gene in 30 strains of *P.aeruginosa* isolated from various clinical samples in a Tertiary Care Hospital. PCR and gel electrophoresis technique was used for the detection of *exoT* gene in *P.aeruginosa* under study. In this study, the prevalence of *exoT* gene was 66.67%. Out of 30 strains of *P.aeruginosa* clinical isolates from the different clinical conditions, 20 (66.67%) detected *exoT* gene in all spreading type of infections caused by *P.aeruginosa. P.aeruginosa* isolates from pus (61.11%), sputum (100%), urine (80%) and bodyfluids (100%) samples showed presence *exoT* gene. Out of 30, 10 (33.33%) strains were found to be negative for *exoT* gene.

In other similar study in southern India, the prevalence of *exoT* was recorded as 84% [13]. Many researches all over the world studied the prevalence of *exoT* genes as an epidemiological marker in pathogenic *P.aeruginosa* causing different type of infections. The prevalence of *exoT* genes has been found to be variable in *P. aeruginosa* isolates obtained from different infections in the world. Prevalence of *exoT* gene recorded in Iran was 36.27% [22] and in Egypt and Romania, prevalence of *exoT* in *P.aeruginosa* clinical isolates were recorded as 100% [12,23].

Role of *exoT* gene is crucial in the causation of spreading type infections. T3SS virulence factors are responsible for seriousness of the infections with raised death rate [24]. The proven role of *exoT* virulence genes in the pathogenicity of *P.aeruginosa* would help in understanding the prognosis of *Pseudomonas* infections and designing an effective vaccine against the pseudomonas infections to prevent them. This may help in epidemiological study, deciding the treatment course for the infections caused by *P.aeruginosa*. These findings may help in identifying virulent gene targets for immune intervention which could regulate the severity of the host response and its effect on impairment caused by *P.aeruginosa*.

The identification of virulent markers of pathogens for identification of acute and chronic infections at early stage remains a critical area and still need large research. Such type of research studies and findings facilitate the prevention of infections caused by bacteria and can be very useful to control the *Pseudomonas* infections.

Limitation(s)

All the *P.aeruginosa* strains under study were obtained from In Patient Department (IPD) only. Therefore, prevalence of *exoT* gene in *P.aeruginosa* could not be studied in Out Patient Department (OPD) patient. Larger sample size of both IPD and OPD patients would have provided better status of prevalence of *exoT* virulent gene marker as well as difference and significance.

CONCLUSION(S)

Gene *exoT* encoding ExotoxinT plays a very crucial role in the causation of disease. The proven role of *exoT* virulence genes in the pathogenicity of *P.aeruginosa* would help in understanding the prognosis of *Pseudomonas* infections and designing an effective vaccine against the *Pseudomonas* infections to prevent them. This may help in epidemiological study, deciding the treatment course for the infections caused by *P.aeruginosa*. In future trends in diagnostic microbiology, focus should be on development of rapid tests required for detection of virulence factors which are important epidemiological markers apart from identification and antimicrobial susceptibility tests.

Abstract

Respiratory syncytial virus (RSV) causes high mortality and morbidity in infants. The study was planned to determine the trends of RSV sub-types in hospitalised children. Nasopharyngeal aspirate and throat swabs were collected from the hospitalised children up to 5 years of age. Viral nucleic acid was extracted using easyMAG automated extraction system, and real-time reverse transcription polymerase chain reaction was performed. Total positivity for RSV was found to be 25.40%, predominantly for RSV B (20.03%), followed by RSV A (2.90%) and RSV AB mixed infections (2.47%). Palivizumab prophylaxis can be planned to be given to infants from post-monsoon to end of winter.

Keywords: Palivizumab, real-time reverse transcription polymerase chain reaction, Respiratory syncytial virus A, respiratory syncytial virus B

Introduction

Respiratory syncytial virus **(**RSV) is an important cause of acute respiratory infections (ARIs) in children; about 60% of children get infected with RSV by the 1st year and 100% by the 2nd year of life.[1] As per the World Health Organization, RSV is responsible for 4 million deaths around the world annually in children <5 years of age.[2] The virus is mostly seen in children with bronchiolitis and pneumonia.[3] Repeated infections and yearly outbreaks of RSV possibly occur due to the antigenic variability of the virus which is a challenge for designing and development of vaccine.[3] To optimise the prophylaxis, it is important to forecast the trends of RSV infection in a given area for better prevention and control.

Materials and Methods

Study duration

The study was conducted over a period of 28 months, i.e., between September 2012 and December 2014.

Ethical clearance

The study was carried out subsequent to clearance from the Institutional Ethics Committee vide letter no MC/EC/2011/227.

DOI: 10.4103/ijmm.IJMM_15_306

Sample collection and transportation

A total of 689 nasopharyngeal aspirates and throat swab samples were collected from patients of ARI by a trained technician, using sterile nylon flocked swabs, and placed in viral transport medium, labelled and transported on ice at the earliest to advanced research laboratory (ICMR Grade-I Virology Lab) of Sawai ManSingh Medical College, Jaipur, for further processing and storage of the samples.

Nucleic acid extraction

One hundred and ten microlitres of viral nucleic acid was extracted from 400 µl of sample using NucliSENS easyMAG automated nucleic acid extractor (BioMerieux) as per the manufacturer's instructions.

Real-time reverse transcription polymerase chain reaction

Initial screening for the presence of RSV was done using previously published primer probes for RSV by real-time reverse transcription polymerase chain reaction amplification[4] (synthesised by Applied Biosystems Inc., USA). Samples positive for RSV were retested separately for RSV A and RSV B on ABI 7500 fast (Applied Biosystems Inc., USA). The primer probe for sub-typing of RSV A and RSV B was synthesised (TIB MOL, from TIB MOLBIOL, Berlin, Germany) as per the published literature.[5]

Results

Six hundred and eighty-nine samples from hospitalised children of age ≤ 5 years were screened for possible RSV infection. The total positivity for RSV was found to be 175/689 (25.40%), 133/490 (27.14%) in males and 42/199 (21.10%) in females. RSV B was found positive in 20.03% (138/689) patients, RSV A in 2.90% (20/689) patients and RSV AB in 2.47% (17/689) patients. Correlation of RSV sub-types in relation to signs, symptoms and clinical syndromes is mentioned in Table 1.

Age-wise distribution of Respiratory syncytial virus A, Respiratory syncytial virus B and Respiratory syncytial virus AB

The occurrence of RSV infections varied in different age groups. Maximum positivity was observed in age group 1–12 months (36.13%), which was statistically significant ($P < 0.001$) (Chi-square test), followed by 13–24 months age group (18.34%); very low positivity was found in other age groups (2.33%–8.82%).

Seasonal distribution of Respiratory syncytial virus A, Respiratory syncytial virus B and Respiratory syncytial virus AB

In the 1st year of the study from September 2012 to August 2013, the only circulating type of RSV was the RSV A with its peak in March 2013, at the end of winter season. In the 2nd year of study from September 2013 to August 2014, both the types and mixed infections, i.e., RSV A, RSV B and RSV AB, were found to be circulating. All the RSV types were found to be circulating mainly during winter months and post-monsoon season [Figure 1].

Discussion

RSV is an important cause of mortality and morbidity requiring hospitalisation in the first few years of life. The present study was first to report the trends of RSV A and RSV B from Jaipur and Rajasthan in the hospitalised children ≤5 years of age. During the study period of 27 months, total positivity of RSV was found to be 25.40%. This is in correlation with an earlier study which reported a positivity of 26%.[6] On RSV typing of positive samples in the present study, predominance of RSV B (78.85%) was observed as compared to RSV A and RSV AB mixed infections. This is consistent with an earlier Indian study from Delhi (64.44%)[7] and other studies globally, from Malaysia (73.36%),[8] Zagreb (83.60%)[9] and Brazil (92.07%).[6] A study from Kolkata (India) reported predominance of RSV B (95%) in the 1st year, which was replaced by RSV A (94.84%) in the consequent years of the study.[10]

In the present study, RSV was positive predominantly (36.13%) in the hospitalised children <12 months of age. RSV is known to be an important cause of hospitalisation in children younger than 1 year of age.[6] This may be due to low levels of immunity in infants.

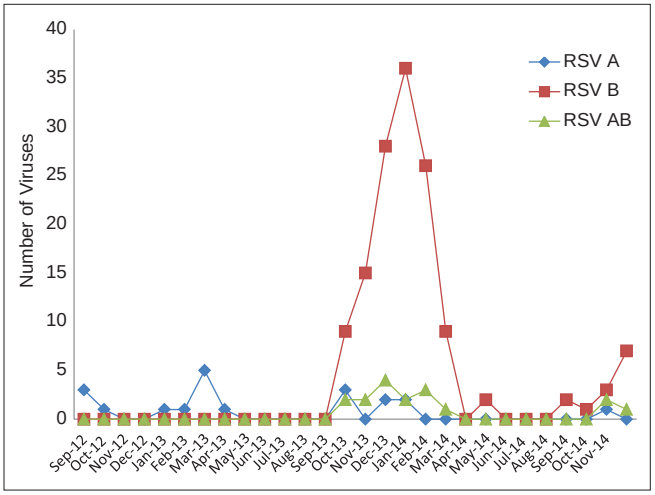

Figure 1: Seasonal variations in Respiratory syncytial virus A and Respiratory syncytial virus B along with Respiratory syncytial virus AB mixed infection.

Table 1: Correlation of Respiratory syncytial virus sub-types in relation to signs, symptoms and clinical syndromes

	RSV A, *n* (%)	RSV B, *n* (%)	RSV AB, *n* (%)	Total RSV
Total	20 (11.43)	138 (78.85)	17 (9.71)	175 (100.00)
Signs and symptoms				
Fever	3 (15.0)	115 (83.33)	16 (94.11)	134 (76.57)
Cough	20 (100.0)	137 (99.27)	17 (100.0)	174 (99.42)
Sore throat	9 (45.0)	3 (2.17)	1 (5.88)	13 (7.42)
Shortness of breath	16 (80.0)	127 (92.02)	16 (94.11)	159 (90.85)
Wheezing	2 (10.0)	2 (1.45)	-	4 (2.28)
Clinical syndrome				
Pneumonia	3 (15.0)	76 (55.07)	11 (64.70)	90 (51.42)
Bronchiolitis	1 (5.0)	20 (14.49)	1 (5.88)	22 (12.57)

RSV: Respiratory syncytial virus

In the present study, pneumonia was observed in 51.42% and bronchiolitis in 12.57% of RSV-positive patients. Earlier studies reported bronchiolitis in 47.1% to 82%[1,11] and pneumonia in 36.2%–76%[1,11] in RSV-positive patients. RSV B was the predominant RSV type detected in the present study in the hospitalised children of ≤5 years of age. RSV B was reported to be a more common cause of bronchiolitis and pneumonia than sub-type A.[9]

During the 1st year of our study, only RSV A was the type of RSV circulating whereas, during the 2nd and 3rd year of the study, all the two types and mixed infections, i.e., RSV A, RSV B and RSV AB, were found to be co circulating. The exact reason for this variation in the circulation patterns of RSV during different years of the study is not known. Similarly co-circulation of RSV A and RSV B has been found in other studies from India and Germany with the predominance of RSV A sub-group.[12,13]

Conclusion

RSV B was the most predominant type circulating in our area with co-circulation of RSV A and RSVAB. Peak positivity was seen in winters and lower positivity in post-monsoon season. Palivizumab can be planned to be given post-monsoon till winters are over. Only hospitalised patients were studied in present study which is a limitation but provides information on trends in serious patients and can provide guidance to plan prevention and control policies.

Aetiological Study of Viruses Causing Acute Encephalitis Syndrome in North West India

Jitendra Kumar Tiwari, Bharti Malhotra, Aradhana Chauhan, Hemant Malhotra[1], Pratibha Sharma, Farah Deeba, Khushbu Trivedi, Anjenya M. Swamy

Department of Microbiology and Immunology, Advanced Basic Sciences and Clinical Research Laboratory, ICMR Grade 1/ DHR State, Sawai Man Singh Medical College, [1]Department of Medicine, Sawai Man Singh Hospital, Jaipur, Rajasthan, India

Abstract

Context: Acute encephalitis syndrome (AES) is a serious public health problem, caused mainly by viruses. However, the profile of viruses causing AES in Rajasthan is not well characterised. **Aims:** The present study was undertaken to identify the viruses causing AES and develop diagnostic algorithm so as to help in improved diagnosis, treatment, prevention and control. **Settings and Design:** The present study is a hospital-based descriptive, observational study. Samples were processed at Grade-1 DHR/ICMR Viral Research and Diagnostic Laboratory at SMS, Jaipur. **Subjects and Methods:** Cerebrospinal fluid (CSF) samples were processed for IgM antibody detection by enzyme-linked immunosorbent assay (ELISA) for mumps virus (MPV), measles virus (MV), Rubella virus (RV), Japanese encephalitis virus (JEV), West Nile virus (WNV) and Dengue virus using commercial kits. Nucleic acid was extracted from CSF using automated extraction system. Real-time polymerase chain reaction was done using specific primers and probes for Herpes simplex virus (HSV), Varicella-zoster virus (VZV), Epstein-Barr virus (EBV), cytomegalovirus (CMV) and enterovirus (EV). **Statistical Analysis Used:** Statistical analysis was done using ANOVA. **Results:** Among 3088 patients, 702 (22.7%) patients were positive for one or more viruses. HSV (261;8.45%) was the most common followed by EBV (173;5.6%), VZV (97;3.1%), CMV (68;2.2%), EV (32;1.03%), MPV (27;0.9%), DV (28;0.9%), MV (19;0.6%) and RV (6;0.2%). **Conclusions:** AES occurred sporadically in Rajasthan, samples should be tested first for herpes group of viruses followed by EV or/and for arboviruses depending on season or measles, mumps and RVs in children.

Keywords: Acute encephalitis syndrome, cerebrospinal fluid, enzyme-linked immunosorbent assay, herpes simplex virus, Japanese encephalitis, polymerase chain reaction

Introduction

Acute encephalitis syndrome (AES) is defined as the acute-onset of fever and a change in mental status and/or new-onset of seizures in a person of any age at any time of the year. AES is an emerging public health problem, claiming thousands of lives[1] and the disease most commonly affects children and young adults and can lead to considerable morbidity and mortality.[2]

Although bacteria, viruses and protozoan parasites may cause encephalitis, among these the viruses are the most common and important cause of encephalitis. Cases of AES have been reported from many states of India, but the aetiological agent has been identified in only 20%–30% cases.[3] Among all, viral encephalitis that is encountered in India, JE appears to be of greater significance during outbreaks as well as in sporadic cases. Herpes group of viruses, enterovirus (EV), measles virus (MV), mumps virus (MPV) and Rubella virus (RV) also constitute significant numbers in sporadic and outbreak cases in India. However, the profile of agents causing AES varies from place to place. Clinically and neurodiagnostic tests can usually establish the presence of encephalitis but do not necessarily establish the aetiologic cause, which often remains unknown.[4]

There is only one report from Rajasthan on aetiology of AES cases, where only HSV was tested.[5] Rajasthan has its own geographic characteristics, and till recently, the state has

How to cite this article: Tiwari JK, Malhotra B, Chauhan A, Malhotra H, Sharma P, Deeba F, *et al*. Aetiological study of viruses causing acute encephalitis syndrome in North West India. Indian J Med Microbiol 2017;35:529-34.

been considered to be non-Japanese encephalitis (JE) area. With better irrigation and paddy cultivation in the state, the vector for Japanese encephalitis virus (JEV) is available, and the risk has consequently increased. The present study was undertaken to identify the viruses causing AES in patients. These results are likely to help in proper diagnosis, treatment, planning prevention and control strategies and in developing diagnostic algorithm in our state. The findings of our study are also likely to help clinicians in the management of AES.

Subjects and Methods

Study design

The present study is a hospital-based descriptive, observational study.

Source population

This study was carried out on patients admitted to SMS and attached group of hospitals, Jaipur.

Period

The study period was November 2011 to December 2016.

Place of study

Samples were processed at Virology Laboratory, Jaipur. Institutional Ethics Committee permission was obtained before initiating the study.

Sample size

The minimum sample size for this study was calculated as 375 with an estimated 0.42 true proportion rate[6] at a confidence level of 95% assuming desired precision rate of 5% using the formula from EpiTools epidemiological calculators $n = (Z^2 \times P\ [1 - P])/e^2$ (where Z is value from standard normal distribution corresponding to desired confidence level ($Z = 1.96$ for 95% confidence interval), 'P' is expected true proportion and 'e' is desired precision (5%). However, to study the trends, all samples meeting criteria and tested over 5 years were included in the study.

Inclusion criteria

Patients presenting with fever of <15 days duration with or without altered sensorium, seizures, headache, vomiting, abdominal pain and paralysis.

Exclusion criteria

Patients suffering from bacterial meningitis, head injury, simple febrile seizures, seizure disorder, heat stroke, metabolic disorders and papilloedema.

Sample collection and transportation

A total of 3088 cerebrospinal fluid (CSF) samples were collected from patients suspected of AES. All samples were received with prior informed consent from the patients/parents/guardians. Detailed pro forma was filled; samples were labelled and sent to lab. Each sample was processed in accordance with established SOPs in the laboratory.

Serological detection

IgM antibody detection by enzyme-linked immunosorbent assay (ELISA) for MPV, MV, RV, JEV, West Nile virus (WNV) and Dengue virus (DV) were done in patient CSF using commercial ELISA kits [Table 1] as per manufacturer's instructions.

Polymerase chain reaction-based detection

Nucleic acid extraction

Briefly, nucleic acid (NA) was extracted by an automatic nucleic acid extractor (NucliSENS easyMAG-Biomerieux) according to the manufacturer's instructions. A total of 300 µl of each CSF sample was loaded in the instrument for on-board lysis, and 60 µl of magnetic silica were added to each specimen after 10 min incubation and mixed well. The NA was extracted in a final volume of 100 µl to be used in real-time polymerase chain reaction (PCR) and an aliquot was stored at 80°C for further use.

Standardisation of real-time polymerase chain reaction

Standardizations were done for real-time PCR by using the positive controls. The cell culture supernatant of Herpes simplex virus (HSV), Varicella-zoster *virus* (VZV), Epstein-Barr virus (EBV), Cytomegalovirus (CMV) and EV were used as positive control which was provided by Manipal Center for Virus Research, Kasturba Medical College (KMC), Manipal.

Amplification and detection of viruses was done on Light Cycler 480 instrument (Roche) as per manufacturer's instructions using their master mix and primer probes as per previously published sequences as given in Table 2.[7-10] Briefly for DNA viruses 10 µl of Light Cycler 480 Probes Master ready mix (Roche), 2 µl of primer probe mix [Table 2], 3 µl of PCR grade water and 5 µl of DNA were added, cycling profile for PCR was; preincubation at 95°C for 10 min followed by 45 cycles of denaturation at 95°C for 10 s, annealing at 55°C for 30 s and extension at 72°C for 1 s.

For the detection of RNA viruses, 20 µl RNA Master Mix (Roche) was used comprising of 0.3 µl enzyme blend,

HSV: Herpes simplex virus, VZV: Varicella zoster virus, EBV: Epstein-Barr virus, CMV: Cytomegalovirus, EV: Enterovirus

3 µl reaction buffer plus 2 µl primer-probe mix, 9.7 µl PCR grade water and 5 µl RNA. Reverse transcription was done at 50°C for 10 min. The cycling profile of PCR was initial denaturation at 95°C for 30 s, followed by 45 cycles of denaturation at 95°C for 1 s, annealing at 55°C for 20 s and extension at 72°C for 1 s. Each assay was run using a positive control and a negative control.

Results

Virus identification, serologically or by molecular testing, was possible in 22.7% of AES suspected patients. The positivity for viruses in male (27.62%) and female (26.85%) was not statistically significant ($P = 1.00$). The positivity in children (41.10%) was significantly higher ($P = 0.0001$) as compared to adults (21.51%) [Table 3].

Most common virus identified in AES suspects in our study was HSV (8.4%) followed by EBV (5.6%), VZV (3.1%), CMV (2.2%), EV (1.0%), MPV (0.9%), DV (0.9%), MV (0.6%) and RV (0.2%). None of the samples were found positive for JE and WNV. Coinfection was seen in nine (0.3%) patients with two viruses each, HSV and VZV in four (0.1%) patients, and HSV and EBV in five (0.16%) patients. Age- and sex-wise distribution for different viruses in positive cases is given in Table 4. Positivity in males was higher than females for HSV and EBV but for other viruses, it was either similar or slightly more in males. The HSV, VZV, EBV, CMV, EV and DV were found more in adults compared to children whereas MPV, MV and RV were found only in children [Table 4].

The most common clinical presentation was fever followed by altered sensorium, seizures, headache, vomiting and abdominal pain [Table 5]. No seasonal variation was observed for all viruses except DV in the present study [Figure 1].

Table 3: Positivity for viruses in patients suspected of acute encephalitis syndrome

Sample	Patients	Male	Female	Children	Adult
Tested	3088	1926	1162	1433	1655
Positive	702	532	312	589	356
Percentage	22.73	27.62	26.85	41.10	21.51

Discussion

There is a wide variation in the viral aetiological agents causing CNS infections across the globe and even in the same continent, and a country.[11] For better management of patients, it is important to know the profile of viruses causing AES in the given area so that immediate action can be taken before laboratory results are available.

In the present study, viral confirmation of AES was documented in only 702 (22.73%) patients. Similarly, other Indian studies have reported positivity from 17.20% to 29.81%, at Odisha (17.2%),[12] at Uttar Pradesh (21.83%),[2] at West Bengal (29.81%)[13] but other studies from India reported higher positivity from 50% to 71.92% at Uttar Pradesh (58.36%),[14] at Karnataka (60%)[9] and at New Delhi (71.92%)[11] Positivity from other countries ranged from 4% to 69% in AES suspected patients.[15-19]

The positivity varies from place-to-place and depends on the number of viruses included in the detection panel; samples included in the study; detection techniques; geographical location; occurrence of any epidemic/outbreak during the study period, etc.

Among the positive cases, Herpes group of viruses were the most common (84.24%) causative agent of AES in the present study. Wide variation in positivity has been reported for Herpes group in India from 13% to 59.10% at Karnataka,[9] Eastern India,[12] and

Table 5: Clinical profile of acute encephalitis syndrome in suspected patients (n=3088)

Clinical features	Cases (%)
Fever	2653 (85.91)
Altered sensorium	1968 (63.73)
Seizures	1596 (51.68)
Headache	1021 (33.06)
Vomiting	653 (21.15)
Abdominal pain	234 (7.58)

UP[2,14] and abroad also from 7.19% to 55%.[16-21] Herpes group remains the most common causative agent in acute sporadic encephalitis cases in the developed world and in India too. All these viruses have specific antiviral therapy available (acyclovir), and early diagnosis can alert the clinician for timely initiation of specific therapy and prevent the high mortality and morbidity which can occur in absence or delay in treatment.

Additional viruses identified in positive cases in our study were EV (4.50%), DV (3.94%), MPV (3.80%), MV (2.67%) and RV (0.84%). EV-71 is an important emerging encephalitogenic virus. Similar to our study, low positivity was observed to these viruses from 0.19% to 2.6% from Eastern India,[12] but higher positivity to all these viruses from one study from Western UP (EV 71 in 42.1%, MV in 21.1%, and MPV in 10.5%).[2] Whereas EV was not reported in another study from UP.[14] On the other hand, very high positivity was reported for EV 71 (35.1%) from New Delhi.[11]

Before the start of nationwide, MMR vaccination programs, mumps and measles were most common causative agents detected in encephalitis suspected children. From developed countries, these organisms have almost disappeared; however, they continue to be most common causative agents of AES in developing countries like India, probably because of suboptimal immunisation rates.[14]

In the present study, none of the samples were found positive for JEV and WNV. Similarly, other studies from India and abroad also did not report JEV, from Western UP,[2] Andhra Pradesh,[22] Taiwan,[20] and Malaysia.[4]

JEV is a big public health problem in India causing frequent outbreaks and high mortality[23-25] but Rajasthan belongs to non-JE endemic area, and even now, no case was reported in our study also. However, there may be some limitations in our study, the kit used of JE was from Inbios and not from NIV moreover majority of our samples belonged to about 22 districts of Rajasthan. There is a need to systematically test samples from all the districts of Rajasthan, especially those where there

has been change in ecosystem due to buildings of dams and canals and presence of JE vector has been reported.

In the present study, co-infection was seen in nine samples with two viruses each HSV and VZV in four samples and HSV and EBV in five samples. Similarly, other studies also reported coinfection. A study from Sweden[15] detected coinfection in two samples with two viruses each; HSV and EBV in one sample and VZV and EBV in the other sample. Authors from Italy[26] reported coinfection in four samples with two viruses each HSV1 and VZV in two samples, HSV1 and HSV2 in one sample and EBV and HSV2 in one sample. Herpes group of viruses may be positive due to reactivation of latent viruses in the setting of a primary central nervous system infectious agent.[27]

In the present study, positivity for AES was found in both children and adults, but it was significantly higher in children ($P = 0.0001$) as compared to adults. Similar findings have been reported in Lucknow, UP, which also showed higher positivity in children.[14] However, many studies conducted for AES in India were limited to children only.[2,11,13,28,29]

The MPV, MV and RV were found positive in children only; whereas other viruses occurred both in children and adults but predominantly in adults. MMR has been reported to mainly affect older teens and young adults, which include the unvaccinated population; this population has probably not developed immunity through exposure to virus because of decreased circulation of the virus after the implementation of childhood immunisation program.[11]

In the present study, the number of males enroled was higher but positivity in both sexes was similar. Although none of the CNS infections are known to have a male predominance, this apparent male predominance can be attributed to the male-dominated social system where a sick male gets preferential medical attention.

In the present study, post-monsoon presence of DV was observed which coincides with seasonal increase in DV infection post-monsoon. However, no distinct seasonal variation was observed for other viruses. Similarly, Jain *et al*. from UP[14] observed a definite seasonality for DV and JEV in monsoon and post-monsoon seasons. While from Gorakhpur, UP[30] reported AES cases throughout the year, but the incidence peaked in post-monsoon period. The seasonal trends depend on the predominant agent involved in each study. Fever with altered mental state was the most common symptom complex in our patients as reported earlier.[31]

Diagnostic algorithm

The diagnostic algorithm which can be followed in our setting is as follows; first panel HSV, EBV and VZV; second panel CMV, EV and DV; third panel MPV, MV and RV; fourth panel JE, WNV and other viruses as per clinical history.

Conclusions

AES occurred sporadically in Rajasthan, samples should be tested first for herpes group of viruses followed by EV or/and for arboviruses depending on season or measles, mumps and RVs in children.

Abstract

Introduction: Various pathogens cause respiratory tract infections in children of <5 years of age causing severe morbidity and mortality. The profile of causative agents varies from place to place. **Aims:** The objectives of our study were to detect the profile and trends of respiratory pathogens causing acute respiratory tract infection in children using a custom multiplex real-time polymerase chain reaction (RT-PCR) and to develop a diagnostic algorithm. **Materials and Methods:** A total of 997 children with clinical manifestations of respiratory infections were included in the study. Their nasopharyngeal aspirate and throat swab samples were subjected to nucleic acid extraction followed by multiplex RT-PCR for eighteen viruses and six bacteria. **Statistical Analysis Used:** Chi-square test was employed to study the *P* value of different viruses and bacteria. **Results:** A total of 765 (76.73%) samples were found to be positive for one of the respiratory pathogens. Viruses were detected in 598 (59.98%) and bacteria in 167 (41.85%) samples, respectively. The prevalence of single and co-infections among viruses and bacteria were 77.76% and 22.24%, 81.44% and 18.56% each, respectively. Respiratory syncytial virus (RSV) A/B and *Streptococcus pneumoniae* were the most predominant pathogens detected in the study and were associated with lower respiratory tract infections. **Conclusion:** RSV and *S. pneumoniae* were the most common pathogens detected, higher prevalence was observed in children <1 year of age. Viruses were predominant during winter months. The study helped to prepare diagnostic algorithm which will help in reducing diagnostic costs. However, further studies are required to assess whether viruses are bystander or real pathogens and include larger panel of bacteria and viruses for diagnosis.

Keywords: Acute respiratory infection, hospitalised children, multiplex real-time polymerase chain reaction, viruses

Introduction

Respiratory infections pose major public health problem worldwide. About 13 million children of <5 years of age, die every year, 95% of them are from developing countries and one-third of the total deaths are due to acute respiratory infections (ARIs).[1] ARI accounts for 30%–50% of the total paediatric outpatient visits and 20%–30% of the paediatric admissions.[2] ARIs are mainly self-limited, but can lead to complications requiring hospitalisation due to severe acute respiratory infections (SARI) which can be fatal at times,[3] cause high economic burden on health care systems and to family of patients.

The causative agents include mainly viruses, up to 60%, (e.g., Respiratory syncytial virus (RSV), Influenza A, Rhinovirus, Adenovirus); bacteria (e.g., *Streptococcus pneumoniae*, *Mycoplasma pneumoniae* and *Staphylococcus aureus*) and fungi (e.g., *Pneumocystis jirovecii*).[4,5] The severity of the disease can be affected by type of infecting agent and predisposing factors such as age, immune status of the host, single or mixed infections and virulence mechanisms of the viral agents.[6] It is important to know the profile and trends of various agents causing RTI in children so as to initiate appropriate therapy. Moreover, due to lack of identification of viruses antibiotics are given which cause undue side effects and also increase antimicrobial drug resistance. There are only few studies enumerating the profile of pathogens causing

How to cite this article: Swamy MA, Malhotra B, Janardhan Reddy PV, Tiwari J. Profile of respiratory pathogens causing acute respiratory infections in hospitalised children at Rajasthan a 4 year's study. Indian J Med Microbiol 2018;36:163-71.

ARI in hospitalised patients.[2] Most of the respiratory pathogens produce similar symptoms as a result it is difficult to identify them clinically. Various commercial and in-house multiplex real-time polymerase chain reaction (RT-PCR) assays are being used for simultaneous amplification of multiple pathogens in a single-reaction mixture, which makes them rapid and cost-effective.[7,8] Hence, the present study was undertaken to identify the profile and trends of various respiratory pathogens in hospitalised children using a validated customised multiplex RT-PCR.

Materials and Methods

Setting

This study was conducted at the Indian Council of Medical Research (ICMR)/DHR Grade-I Virology reference Laboratory-Advanced Research Laboratory, Department of Microbiology and Immunology, S. M. S. Medical College, Jaipur during 2012–2016. The study was approved by Institutional Ethics Committee.

Patient's enrolment

All the patients enroled in the study were freshly diagnosed and hospitalised cases. Any previous history of respiratory infections was excluded from the study to prevent the detection of residual nucleic acid. Written consent was obtained from the parent/guardian. Clinical signs and symptoms of children enroled in the study were noted in pro forma for fever, cough, nasal catarrh, shortness of breath, sore throat, wheezing, bronchiolitis and pneumonia.

Sample collection and transportation

Nasopharyngeal aspirate and throat swabs from 997 children (age range 1–60 months) with acute respiratory illness were collected in 3 ml of viral transport media. Samples were labelled and transported on ice packs at the earliest to the laboratory. On reaching the laboratory, samples were registered and given a unique identification number before aliquoting for processing and storage.

Nucleic acid extraction

Nucleic acid from samples was extracted using NucliSENSE EasyMAG (Biomeurex) automated extractor according to the manufacturer's instructions, 110 µl of nucleic acid was eluted from a volume of 400 µl sample.

Previously standardised customised multiplex PCR was used for identification of various viruses,[7] bacterial PCR standardisation was done using the same protocol but tested in duplex in samples negative for any virus [Table 1].

Statistical analysis

Chi-square test was employed to study the *P* value of different viruses and bacteria.

Results

Viruses detected in children

Out of 997 children enroled, 598 (59.98%) children were positive for at least one of the respiratory viruses of which co-infections were detected in 133 (22.24%) children. Single infection was observed in 465 (77.76%) children [Table 2]. The most common virus detected in the study (including single and co-infection) was RSV A/B in 279 (37.35%), followed by human rhinoviruses (HRV) 106 (14.19%) and HAdV 83 (11.11%). The profile of viruses causing ARIs is mentioned in Table 2. Details of co-infections of different viruses are mentioned in Table 3.

Clinical features and association with respiratory viruses

Cough and fever were the most common clinical manifestation followed by shortness of breath, pneumonia and bronchiolitis [Table 4]. The RSV A/B was predominant in cases presenting with pneumonia and bronchiolitis.

Viruses among different age groups

Positivity for respiratory viruses was found to be more in the age group of 1–12 months; 495 (66.26%) cases, followed by 13–24 months' age patients with 101 (13.52%) cases and 25–36 months' age patients, 65 (8.70%). Most of the viruses were found predominantly in the age group of 1–12 months as compared to other age groups [Table 2].

Seasonal trends of respiratory viruses

During the study, respiratory viruses were predominant during the winter months [Figure 1], RSV A/B had its high peaks in December and January while human

*P<0.05. Flu A: Influenza A, Flu B: Influenza B, EV: Enterovirus, RSV A/B: Respiratory syncytial virus, HMPV A/B: Human metapneumovirus, HRV: Human rhinovirus, HPeV: Human parechovirus, HBoV: Human bocavirus, HAdV: Human adenovirus, HPIV: Human parainfluenza virus, HCoV: Human coronaviruses

metapneumovirus (HMPV) A/B and Pandemic H1N1 had only single peak in February 2013 and for HAdV in December 2014 and 2015 only. HRV was found to be circulating throughout the year irrespective of the seasons, having high peaks in March, May and December.

Statistical analysis

On Chi-square test, *P* value was found to be significant for some viruses such as RSV ($P < 0.0001$), HMPV A/B ($P = 0.001$), pandemic H1N1 ($P = 0.0022$), Flu A ($P = 0.0165$) and EV ($P = 0.0167$) when age-wise intergroup comparisons were made for each virus.

Bacteria causing ARI

Among samples negative for respiratory viruses, 167 (41.85%) were positive for bacteria. Among these, *S. pneumoniae* was the most common, positive in 127 (62.18%) cases followed by *Moraxella catarrhalis* in 60 (29.85%) cases, [Table 5]. Predominance of bacterial agents was also found in the age group of 1–12 months. $P < 0.05$ was observed for *S. pneumoniae* and *M. catarrhalis*.

Diagnostic algorithm

Based on the viruses/bacteria detected in the study and the severity of the disease that they cause, a diagnostic algorithm was developed [Figure 2].

Table 3: Incidence of co-infections of respiratory viruses

Discussion

Respiratory infections claim many lives globally every year. Profile and trends of pathogens causing respiratory infection varies from place to place and as per season and geographic conditions, data from India are very limited hence the present study was done.

In the present study, the overall positivity for viral and bacterial pathogens was found to be 76.73%, whereas a study from Dhaka[5] reported a positivity of 82.5%. This could be due to many reasons such as low-sample size etc. Predominant virus detected in the present study was RSV A/B (37.35%), as also reported from New Zealand (39%),[22] while wide variation was reported from China (13.06%)[23] and Malaysia (70.6%).[24] The variations in detection rates by various studies may be due to sampling methods, genetic variability among the populations, number of samples enroled in the study, samples collected during different seasons of the year and the method used for detection. RSV is known to be an important cause of hospitalisation in children younger than 1 year of age,[25] this may be due to lower immunity in infants.[26,27]

Higher numbers of HRV infections were seen in children of 1–12 months in our study than other age groups as also reported from Latin America.[28] Tregoning and Schwarze 2010[29] reported that RSV and HRV are the most common causes of acute respiratory viral infections as also seen in present study. The positivity of other respiratory viruses, i.e., HAdV, HMPV, HPIV-1 to HPIV-4, HCoV-OC43, HCoV-229E, HCoV-NL 63, HCoV-HKU1, EV, HBoV, Pandemic H1N1, Flu A, Flu B and HPeV were between 11.11%–0.13% [Table 2]. An Indian study by Singh *et al.*, 2014[25] reported no positivity of HPIV 1–4 and 1.10% for HBoV and 7.74% for Influenza (Flu A and Flu B) in hospitalised children with ALRI.

The prevalence of respiratory pathogens were found to be higher in the age group of <1 year with more predilection to RSV A/B and S. *pneumoniae* and higher co-infection as also reported by Bhuyan *et al.*, 2017.[5] Most of the viruses in our study were associated with both upper and lower respiratory tract infections. However, RSV A/B and *S. pneumoniae* were mostly associated with lower respiratory tract infections (i.e. bronchiolitis and pneumonia) in our study and at Dhaka too.[5] On comparing seasonal variation, in our study RSV A/B showed its highest peak in winters, during January similarly a study from Madagascar reported RSV A/B peak in February.[30] HMPV A/B also had highest peak in February as reported from Karachi also.[31] Thereafter, no peaks of HMPV A/B were observed and HMPV A/B was replaced by RSV A/B as the predominant virus which continued in the entire study as the major virus. Continuous positivity with a peak of pandemic H1N1 was observed from December 2012 to April 2013. This may be due to the high prevalence of pandemic H1N1 in the study region. HRV was found to be circulating almost entire year with peaks in March, May and December.

Positivity of the respiratory viruses was not continuous throughout the years. Some studies reported circulation of the respiratory viruses throughout the year, whereas others show distinct seasonality,[24] which could be due to seasonal variations of host immune response, climatic changes, which may promote the viral growth.[25] Low temperatures may favour the circulation of the viruses. The information on seasonal positivity of respiratory pathogens can help public and clinicians to take necessary preventive measures to control respiratory infections.

Timely identification of virus etiology in such patients can prevent misuse of antibiotics and emergence of multidrug-resistant bacteria. Moreover, the detection of fastidious bacteria by RT-PCR could help patient by initiating appropriate therapy timely. *S. pneumoniae* was the predominant bacterial agent as also reported from Dhaka,[5] who report it to be an important cause of mortality in children <5 years of age.[5] The overall positivity

Legionella pneumophila	-	-	-	-	-	-	-	-	-
Total	163	17	12	3	6	136 (100.0)	65 (100.0)	201 (100.0)	-
Samples									
Positive	134	14	11	3	5	136 (81.44)	31 (18.56)	167 (41.85)	-
Negative	124	48	30	12	18	-	-	232 (58.15)	-
Total	258	62	41	15	23	-	-	399 (100.0)	-

for the bacterial agents was found to be 41.85%. Although the detection rate of *Mycoplasma pneumoniae* was only 1.99% out of which 1.49% were associated with pneumonia. Even though *M. catarrhalis* was second-most predominant bacteria detected in the study its role in respiratory infections needs to be evaluated further as it is a known commensal. In children, <5 years high prevalence of both bacterial and viral pathogens was observed. Immature immune system may be the reason behind this. Although bacteria cause secondary infections after viral infections, they should not be excluded from screening.

A diagnostic algorithm was prepared based on the severity of the disease caused and frequency of detection of pathogens. This will help in rapid economic diagnosis. However, there were some limitations in our study, only viral negative samples were screened for bacteria, screening of all samples would have given better picture; moreover, only limited panel of bacteria were tested and antibiotic sensitivity testing was also not done. Further studies are required including these parameters to answer all questions.

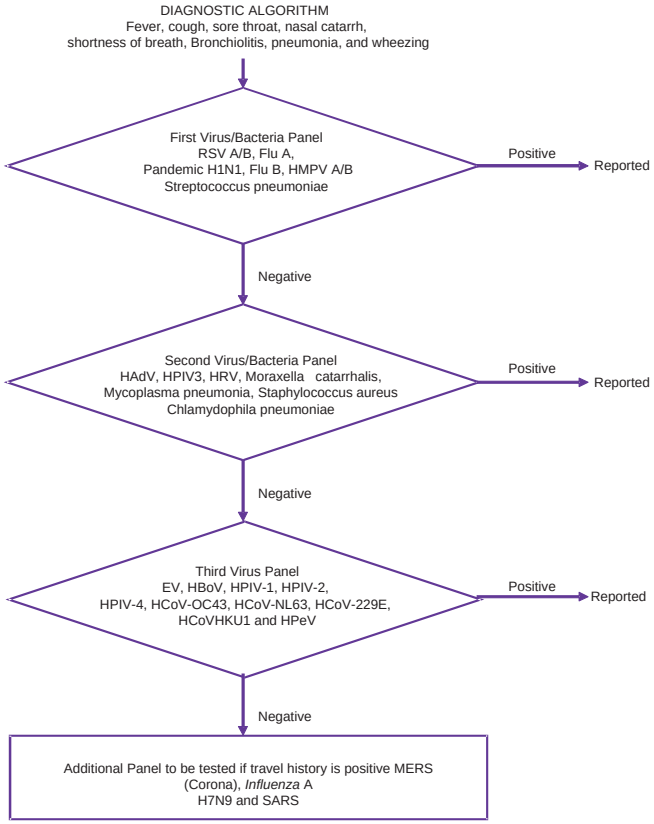

Figure 2: Flow chart of diagnostic algorithm

Conclusion

The RSV A/B, HRV, HAdV and HMPV A/B respiratory viruses were more prevalent than others and that too in winter months. Children aged <1 year were more vulnerable to respiratory viruses and bacteria, diagnostic algorithm developed can help provide rapid economic diagnosis. Rapid early identification of viruses and fastidious bacteria by PCR can help start proper therapy timely and prevent misuse of antibiotics and development of antimicrobial drug resistance. However, inclusion of all bacteria responsible for respiratory infections and the drug resistance markers can further help in patient care, additional studies are required to know whether the agent identified is a bystander or a true pathogen. This will also help in planning strategies for vaccination.

ABSTRACT

Background: Since there is a significant rise in resistant bacteria to different antimicrobial agents, there is a need to study the resistance pattern of different isolates from different clinical samples for effective use of available antimicrobials by clinicians. The aim of the present study was to detect the resistance pattern of various antimicrobials against different clinical isolates in hospitalised patients in out setting.
Methods: This is a retrospective study involving the collection of the data from the records of microbiology laboratory. All clinical specimens were processed as per standard microbiological procedures. Antibiotic susceptibility testing was performed by Kirby Bauer disc diffusion method on Mueller Hinton agar plate as per CLSI guidelines.
Results: A total of 153 isolates were recovered from 219 clinical samples accounting for 69.86% of total positivity. Which includes gram negative bacilli 107/153 (69.93%) gram positive cocci 36/153 (23.53%) and yeast 10/153 (6.54%). Among the total isolates gram negative bacilli account for major number of isolates 69.93% followed by gram positive cocci 23.53% and yeast 6.54%. Gram positive cocci and gram-negative bacilli showed a significant level of antimicrobial resistance. Nitrofurantoin is highly effective against urinary isolates of *Escherichia coli.* vancomycin and linezolid are most effective antimicrobials against gram positive cocci. Among gram negative bacilli meropenem and amikacin are most effective antimicrobials. Statistical significance of occurrence of *Escherichia coli* as predominant isolate as compared to other isolates were analysed by chi square test by using GraphPad online calculator. A p value<0.001 was obtained.
Conclusions: Significant rise in antimicrobial resistant pathogens were observed. Local antimicrobial policy should be developed for effective selection of available antimicrobials which are the need of the day to reduce the burden of diseases on global health care system.

Keywords: Antimicrobial resistance, Gram negative bacilli, Gram positive cocci

INTRODUCTION

Infections with microbes has a drastic effect on human health.[1] Microbial infections are important cause of morbidity and mortality across the globe with increase resistance of pathogens to different antimicrobial agents posing great concern to public health.[2] Antimicrobials are being used to overcome the drastic effect of microbial agents. Their wide spread use has led to emergence of multidrug resistant (MDR) pathogens. Antimicrobial resistance (AMR) may be due to natural, acquired/clinical resistance.[1]

High morbidity and mortality are seen in infections caused by drug resistant pathogens. The pattern of resistance to various antimicrobial agents may change over a period of time.[3] Nosocomial infections pose a great challenge to the well fare of the patient

management, since most of them are MDR strains. This increases the hospital stay of in patients and increases the health care cost.[1]

AMR is a great health care problem in India.[4] The burden of infectious disease is more in India because of increased drug resistant bacteria due to indiscriminate use of antimicrobials. Frequent cause of hospitalisation is associated with different microbial infections. The choice of selecting an effective antimicrobial agent has been reduced because of their resistance to different pathogens causing hospital and community acquired infections.[5]

Patients infected with drug resistant pathogens are at high risk of serious clinical outcomes and require more heath care services. Resistance to different antimicrobials is seen because of indiscriminate use of different antimicrobial agents, which in turn leads to mutations and results in drug resistance. MDR bacteria pose great threat for patients. since, it becomes very difficult to treat such patients and requires use of broad-spectrum antibiotics.[6]

METHODS

This was a retrospective study which involves analysis of medical microbiology test results of different clinical samples collected over a period of 6 months between July 2019 to December 2019. Only IPD patients were included in the study. The study was carried out at Ananta Institute of Medical sciences and research center, Rajsamand. This is a tertiary care hospital.

Data collection and testing

Type of clinical samples, isolates, age, sex and their antimicrobial susceptibility pattern were collected from the records. All clinical specimens were processed as per standard microbiological procedures. The isolates were first identified by standard biochemical techniques and then subjected to antibiotic susceptibility testing by Kirby Bauer disc diffusion method on Mueller Hinton agar plate as per CLSI guidelines.[5]

Antibiotic discs

The following antibiotic discs containing amikacin AK 30 mcg, amoxycillin/clavulanic acid AMC 30 mcg, ampicillin/sulbactam A/S 10/10 mcg, azithromycin AZM 15 mcg, aztreonam AT 30 mcg, cefoxitin CX 30 mcg, ceftizoxime CZX 30 mcg, ceftriaxone CTR 30 mcg, cefuroxime CXM 30 mcg, ciprofloxacin CIP 5 mcg, clindamycin CD 2 mcg, colistin CL 10 mcg, erythromycin E 15 mcg, gentamicin GEN 10 mcg, imipenem IPM 10 mcg, levofloxacin LE 5 mcg, linezolid LZ 30 mcg, meropenem MRP 10 mcg, piperacillin/ tazobactum PIT 100/10 mcg, polymyxin-B PB 300 units, trimethoprim TR 5 mcg, vancomycin VA 30 mcg, cefoperazone/ sulbactam CFS 75/10 mcg, ceftazidime/clavulanic acid CAC 30/10 mcg, nitrofurantoin NIT 300 mcg were used as per manufacturer (Himedia) instructions.

Statistical analysis

Statistical analysis was done by using GraphPad online calculator. Chi square test was employed. P value<0.05 is considered as statistically significant

RESULTS

A total of 153 isolates were recovered from 219 clinical samples accounting for 69.86% of total positivity. Which includes gram negative bacilli 107/153 (69.93%) gram positive cocci 36/153 (23.53%) and yeast 10/153 (6.54%). Among the total isolates gram negative bacilli account for major number of isolates 69.93% followed by gram positive cocci 23.53% and yeast 6.54% (Table 1).

Among the gram-negative bacilli, the major isolates are *Escherichia coli* 35.29% followed by *Klebsiella* species 12.41% and *Pseudomonas aeruginosa* 12.41%. Among the gram-positive cocci, the major isolates are coagulase negative *Staphylococcal species* (CONS) 12.41% followed by coagulase positive *Staphylococcus* (*Staphylococcus aureus*) 6.53% and *Enterococcus faecalis* 4.57%. Among the yeast the major isolate is *Candida albicans* 4.57% followed by *Candida tropicalis* 1.96% (Antifungal agents were not tested).

Among different clinical samples received urine samples account for highest number of isolates 62/119 (52.10%). Among which gram-negative bacilli accounts for 53/62 (85.48%) followed by gram positive cocci 5/62 (08.06%) and yeast 4/62 (06.45%). *Acinetobacter* species were predominant in clinical aspirates 10/21 (47.61%). *Pseudomonas aeruginosa* was predominant in pus 11/48 (22.91%) (Table 1). A total of 10 co-infections were detected among the total isolates (Table 1).

Antimicrobial resistance

Antimicrobial resistance pattern of gram-negative bacilli and gram-positive cocci varied from nil to 100% for different isolates. The details of each isolate and their antimicrobial resistance pattern is given in Table 2 and 3.

Among gram negative isolates, meropenem and amikacin are more effective against *E-coli* with 9.25% and 18.51% resistance respectively each. Meropenem and piperacillin/ tazobactam are more effective against *Klebsiella* species with 36.84% and 47.36% resistance respectively each. Amikacin and ciprofloxacin are more effective against *P. aeruginosa* with 15.78% and 31.57% resistance respectively each. Amikacin, ampicillin/sulbactam and levofloxacin are more effective against *Acinetobacter* species with 41.66% resistance respectively each. Polymyxine-B and colistin showed no resistance when used against *P. aeruginosa* and *Acinetobacter* species. Piperacillin/ tazobactam is more effective against proteus species with 33.33% resistance (Table 2).

Among gram positive isolates ampicillin/sulbactam, cefoxitin/clindamycin are more effective against cons with 21.05% and 26.31% resistance respectively each. Clindamycin and trimethoprin/ sulphamethoxazole are more effective against *S. aureus* with 30% and 60% resistance respectively each. Gentamicin and Trimethoprin/ sulphamethoxazole more effective against *Enterococcus faecalis* with 14.28% and 57.14% resistance respectively each. Gentamicin is nil resistant to CONS and *S. aureus*. Linezolid and vancomycin are nil resistant to *Enterococcus faecalis*, CONS and *S. aureus* (Table 3). Among total number of clinical isolates, males accounted for (54.25%) positivity and females accounted for (45.75%) positivity. Among the male patients the predominant isolates are *E-coli* (30.12%), followed by *P. aeruginosa* (16.86%) and *Acinetobacter species* (14.45%). Among the female patients the predominant isolates are *E-coli* (41.42%), CONS (15.71%) and *Klebsiella* species (12.85%). Details of each isolate in males and females are mentioned in Table 4.

Statistical significance of occurrence of *Escherichia coli* as predominant isolate as compared to other isolates were analysed by chi square test by using GraphPad online calculator. A p value<0.001 was obtained.

Table 1: Different microbial agents isolated from various clinical samples.

Isolated micro-organism (%)		Clinical sample	Single infection	Co-infection	Total
Gram negative Bacilli (A)	*Acinetobacter* species (7.84)	Aspirates	9/21	1	10/21

DISCUSSION

Different pathogens are associated with human infections. Management of this infectious diseases by timely identification and selection of effective antimicrobials against the causative agents help in early recovery of the patients and also helps in reducing the hospital costs as well as the stay time in hospital. Emergence and spread of MDR pathogens are a major challenge for better health care management. MDR pathogens increase morbidity and mortality in hospitalised patients. This study present various pathogens isolated from different clinical samples and their antimicrobial activity in hospitalised patients.

The total positivity of the clinical isolates of the present study were 69.86% with predominance of gram-negative bacilli 69.93% as compared to gram positive cocci 23.53%. An earlier study has reported a total positivity of 64.70% which correlates with our study.[7] Abebe et al and Masyeni et al reported gram-negative bacilli as the most predominant isolate. Similar findings are observed in the present study. Most of the nosocomial infections are associated with gram negative bacilli causing severe form of the disease. These strains are mostly MDR.[3,8]

The present study has reported a high-level resistance to various class of antimicrobials against gram negative bacilli and gram-positive cocci. Antibiotic resistance is a threat to the world and is a major public problem in India. since, India harbours great burden of bacterial diseases. Emergence of MDR strains from India for gram negative bacilli and gram-positive cocci has been reported.[9] This coincides with the present study which shows high resistance of bacteria to various antimicrobials.

Urine samples accounted for majority (54.33%) of the samples in the present study. similar findings have been observed with other studies.[1,5] The most common pathogen isolated from all clinical samples in our study was *Escherichia coli* 35.29% with predominance of females (57.05%) as compared to males (42.95%). This is followed by *Klebsiella* species, CONS and *Pseudomonas aeruginosa* 12.41% each. These findings are in correlation with other studies.[2,9,10] Among the uropathogens isolated, *Escherichia coli* and *Klebsiella* species were the predominant isolates in our study which correlates with earlier studies.[5,12]

Among the antimicrobials used against *Escherichia coli*, meropenem showed 09.25% resistance, amikacin showed 18.51% resistance and piperacillin/ tazobactam showed 29.62% resistance. Nitrofurantoin showed nil resistance against *Escherichia coli* isolates from urine. similar findings were also reported by other studies with decreased potency of ciprofloxacin and co-trimoxazole among uropathogens.[5,6,10] Among *Klebsiella* species isolated meropenem is more effective which showed 36.84% resistance. This finding is different from an earlier study which reported 100% resistance.[4] In *Pseudomonas aeruginosa* nil resistance was observed for polymyxine-B and colistin. Amikacin showed least resistance 15.78% to *Pseudomonas aeruginosa* followed by meropenem 26.31%. Higher rate of resistance for amikacin (78.00%) and meropenem (100.00%) was reported by an earlier study.[4] *Acinetobacter* species showed nil resistance to polymyxine-B and colistin and 41.66% resistance to amikacin, ampicillin/ sulbactam and levofloxacin respectively each. Piperacillin/tazobactam was the most effective antimicrobial against proteus species with 33.33% resistance. This finding is different from a previous study which reported 100.00% resistance to piperacillin/ tazobactam.[4]

Among the gram-positive isolates nil resistance was observed for vancomycin, linezolid. Gentamicin showed nil resistance against CONS and *Staphylococcus aureus* but showed 14.28% resistance against *Enterococcus faecalis*. Among CONS, ampicillin/sulbactam was the most effective antimicrobial with a resistance of 21.05% followed by cefoxitin and clindamycin with 26.31% resistance. This finding is different from an earlier study which reported 100% sensitivity to cefoxitin and clindamycin.[5] *Staphylococcus aureus* showed least resistance to clindamycin (30%). This finding is different from an earlier study which reported 100% resistance to Clindamycin.[5] Trimethoprin/ sulphamethoxazole showed a least resistance of 57.14% when used against *Enterococcus faecalis.* Khatun et al reported a higher resistance of 75% to trimethoprin/ sulphamethoxazole. The difference in the resistance pattern of different antimicrobials for gram negative bacilli and gram-positive cocci in different studies may be attributed to the usage of that particular antimicrobial in different settings.

High rate of resistance to various antimicrobials in our study may be due to inclusion of only hospitalised patients. Since nosocomial infections are seen in hospitalised patients and the strains are generally resistant to most of the commonly used antimicrobials. Similar

findings were observed by earlier studies which included IPD and OPD patients.[5,6] The high rate of antimicrobial resistance in IPD patients may indicated the need for surveillance studies on nosocomial infections to identify the source of infection. Incorrect diagnosis may lead to irrational use of antibiotics which may lead to overuse or misuse of antimicrobials resulting in dissemination of antibiotic resistance.

CONCLUSION

The most predominant isolate from different clinical samples in our study was *Escherichia coli*. Among gram negative isolates in the present study, the most effective antimicrobials are colistin, meropenem, amikacin, piperacillin/tazobactam, ampicillin/ sulbactum. Among urinary isolates of *Escherichia coli*, nitrofurantoin is very effective. Gentamicin, vancomycin and linezolid are most effective antimicrobials against gram positive cocci in our study. Significant rise in resistance to antimicrobials was observed in this study. Local antimicrobial policy should be developed for effective selection of available antimicrobials which are the need of the day to reduce the burden of diseases on global health care system.

ABSTRACT

Background: Bacteria associated with blood stream infections are an important public health problem which results in morbidity and mortality globally. Emergence of multidrug resistant isolates in hospitalized patients is a major problem. Automation techniques play a major role in early identification of the isolate and its drug susceptibility testing which is important for better outcome of the treatment. This study was aimed to detect the blood stream isolates and their drug susceptibility pattern in hospitalized patients.
Methods: This was a retrospective study conducted from 377 records of automated blood culture (bact/alert) and drug susceptibility testing (vitek) results. Positive blood culture bottles were sub cultured to different culture media and the isolates were identified and screened for drug susceptibility testing on Vitek II.
Results: Around 20.68% of samples were positive for blood stream infections caused by different pathogens. A total of 78 microorganisms were isolated from 377 samples. Among which gram negative bacilli was observed in 52.56%, gram positive cocci in 44.87% and yeast in 2.56% samples. Coagulase negative *staphylococci* and *Klebsiella pneumoniae* were the predominant isolates of the study.
Conclusions: Early diagnosis of blood stream infections in hospitalized patients is life saving. Hence a continuous monitoring of isolates and their drug susceptibility is the need of the day.

Keywords: Blood stream infections, Coagulase negative *staphylococcus, Klebsiella pneumoniae*

INTRODUCTION

Blood stream infection (BSI) remains one of the foremost important causes of morbidity and mortality globally. The infection may range from self limiting to life threatening sepsis.[1,2] As case fatality rate is high it requires appropriate and immediate antimicrobial therapy. Different bacteria were associated with (BSI) from time to time at different geographical areas. These bacteria play an important role in causing mortality, increasing the length of hospital stay and also the health care cost.[3]

Drug resistance of these bacteria is an important issue of public health concern. Since many studies have reported that gram negative and gram positive bacteria are associates with these infections which are often drug resistant. Empirical antibiotic therapy is initiated in almost all cases before the blood culture reports are available. Choice of right empirical therapy is important. An early blood culture report may help in selection of appropriate antibiotics.[2,4]

Minimal time is required to get a blood culture report using automated systems. The etiology and antimicrobial pattern of (BSI) may vary at different times in the same region hence a continuous update is essential for epidemiological purpose and also for rational and accurate use of antibiotics by clinicians. The present

study aimed to determine the etiology and antibiotic resistance pattern in blood stream infections.

METHODS

Study design

A retrospective study was conducted from the records of automated blood culture (bact alert) and drug susceptibility testing (vitek) results in the clinical microbiology laboratory from June, 2016 to July, 2018 at Ananta institute of medical sciences and research centre, Rajsamand. This data includes 377 records of hospitalised patients who were admitted to different units of hospital during the study period.

Sampling technique and data collection

Blood cultures were performed for different age groups up to 90 years. Samples were collected by phlebotomist from the patients after disinfection of vein puncture site with 70% alcohol. 3-4ml of blood was inoculated in 30ml BacT/Alert blood culture bottles for paediatrics and 4-5ml blood was inoculated in 30ml BacT/Alert blood culture bottles for adults. These bottles were incubated in BacT/Alert automated system. The bottles which showed positive signal for growth were removed from the automated system and subculture was done on Nutrient agar, blood agar and MacConkey's agar. Smears from the colony of different agar plates were prepared and stained with Gram stain to identify the growth (i.e. gram positive or gram negative bacteria). Then the growth of the bacteria was run on VITEK II automated system for identification of the organism and Antibiotic Sensitivity. If there is no growth of bacteria within five days of inoculation of blood sample into BacT/Alert blood culture bottle then the sample is considered to be negative.

Data regarding the age, sex, isolate and its antimicrobial pattern was collected and statistical analysis of the data was done by Chi square test to study the P value using social science statistics online software.

RESULTS

A total of 377 samples were screened for blood culture from hospitalized patients of different units. 20.68% of samples were positive for blood stream infections caused by different pathogens (Table 1).

A total of 78 microorganisms were isolated from 377 samples. Among which gram negative bacilli was observed in 52.56%, gram positive cocci in 44.87% and yeast in 2.56% samples. The leading isolate among the gram positive cocci were CONS (coagulase negative *staphylococci*) and among the gram negative bacilli, *Klebsiella pneumoniae*. Details of each isolate were mentioned in Table 1. Only two samples were found to be positive for yeast i.e. *Candida tropicalis*.

Table 1: Bacteria and yeast isolated from blood culture samples.

	Isolate	Positive %
Gram negative bacilli (A)	*Acinetobacter baumannii*	4 (9.75%)
	Acinetobacter iwoffii	1 (2.44%)
	Burkholderia cepaciae	1 (2.44%)
	Escherichia coli	10 (24.39%)
	Enterobacter cloacae Complex	2 (4.87%)
	Klebsiella pneumoniae	17 (41.46%)
	Pseudomonas aeruginosa	3 (7.31%)
	Spingomonas paucimobilis	1 (2.44%)
	Stenotrophomonas maltophilia	1 (2.44%)
	Serratia marcescenes	1 (2.44%)
Total		41 (100%)
Gram positive cocci (B)	*Staphylococcus aureus*	3 (8.57%)
	Staphylococcus cohnii#	2 (5.71%)
	Staphylococcus epidermidis#	6 (17.14%)
	Staphylococcus haemolyticus#	4 (11.48%)
	Staphylococcus hominis#	3 (8.57%)
	Staphylococcus lentus#	2 (5.71%)
	Staphylococcus pseudintermedius#	2 (5.71%)
	Enterococcus faecalis	3 (8.57%)
	CONS	10 (28.57%)
Total		35 (100%)
Yeast (C)	*Candida tropicalis*	2(100%)
Total (A+B+C)		78/377* (20.68%)

*Total number of samples tested, CONS-coagulase negative *staphylococcus*, # CONS

Isolates were predominant in males (62.82%) as compared to females (37.18%) (Table 2). Paediatric patients were more (31.57%) exposed to BSI than adult and elderly patients (23.52%). Statistical analysis showed a P value of 0.03. CONS were the leading pathogens in paediatric patients. *Klebsiella pneumoniae* was the leading pathogen among the adult and elderly patients. 83.3% (65) of samples were culture positive in <24hours, 15.4% (12) in between 24 <48hours, 1.3% (1) between 48-72hours.

Table 2: Sex wise and age wise distribution of positive and negative blood culture samples.

Variable	Blood culture result			P value
	Positive	Negative	Total	
Male	49	191	240	X^2=0.03 P=0.86
Female	29	108	137	
Age				
<5 years	25	58	83	X^2=6.88 P=0.03
5 <15 year	5	37	42	
>15 years	48	204	252	

Among the gram-negative isolates, *Escherichia coli* showed 100% sensitivity to colistin and tigecycline, 80% to ertapenem. *Acinetobacter* species showed 80% sensitivity to colistin and 70% to amikacin. *Enterobacter cloacae* showed 100% sensitivity to tigecycline,

Klebsiella pneumoniae showed 100% sensitivity to colistin and 88.3% to tigecycline. *Pseudomonas aeruginosa* showed 66.7% sensitivity to colistin (Table 3). Among gram positive isolates, CONS showed 93.1% sensitivity to linezolid, 89.7% to tigecycline and 86.2% to vancomycin. *Staphylococcus aureus* showed 100% sensitivity to oxacillin, gentamicin, linezolid, vancomycin, tetracycline and tigecycline. E*nterococcus faecalis* showed 100% sensitivity to gentamicin, linezolid and vancomycin (Table 4).

Very low positivity 1 (2.44%) was observed for *Spingomonas paucimobilis, Stenotrophomonas maltophilia, Burkholderia cepaciae* and *Serratia marcescenes.*

Table 3: Antibiotic resistance of gram negative bacilli isolated from blood culture.

Antimicrobial agent	Resistance percentage of gram negative bacilli

Tetracycline	27.6	0	50
Tigecycline	10.3	0	100
Trimethoprim	51.7	66.6	50

DISCUSSION

The overall frequency of blood culture isolates in present study was (20.68%). This is comparable with studies conducted in India by Pal et al, 2016 (22.3%) and Gill et al, 2016 (24.8%).[5,4] However, some studies have reported high frequency of bacterial pathogens from blood cultures (24.2%-37.1%).[6,7] This may be due to use of different blood culture systems, different sample size, variations in study design and protocols, different geographical locations, variations in causative agents and the policies adopted for infection control between countries. Incidence of gram negative bacilli (GNB) was 52.56% and gram positive cocci (GPC) were 44.87%. Similar findings with high frequency of GNB as compared to GPC were previously reported by an Indian study.[8]

In our study, coagulase negative *staphylococcus* was the leading blood culture isolates (37.1%). Similar results were reported from India (61%) and globally (42%).[9,10] They often occur as skin contaminants during the collection of blood. Cross infections in ICU'S with multidrug resistant CONS can be prevented by use of appropriate antimicrobial agents. There is a need for differentiation between true pathogen and contaminant which can be achieved by correlating clinically the blood culture isolate and time taken for positivity of CONS.[11] Among the GPC group CONS showed high frequency of antimicrobial resistance as compared to others (Table 4). *Staphylococcus* aureus was 100% sensitivite to oxacillin, gentamicin, linezolid, vancomycin, tetracycline and tigecycline. Similarly, an earlier study reported 100% sensitivity to linezolid and vancomycin.[8]

Enterococcus faecalis was observed in (8.5%) of gram positive cocci. Similar findings (8.4%) were reported by an earlier Indian study.[11] It is a normal flora of female genitourinary tract and gastrointestinal tract. Though vancomycin resistance was reported since a decade, in the present study no resistance to vancomycin was observed for *Enterococcus faecalis*. This may be due to differences in the circulating strains. However, an earlier study from north India reported 23% of vancomycin rersistant enterococci.[11]

Gram negative bacteria accounted for more than fifty percent among the total isolates of the blood culture. This is consistent with an earlier study, though there is difference in the range of isolates.[1] Among the non fermenters, *Acinetobacter* species and *psuedomonas aeruginosa* showed high level resistance to cephalosporins and carbapenems. There is increase in the trend of carbapenem resistance to *Acinetobacter* species.[11] This may be because of extensive use of these antimicrobials. The overall antimicrobial resistance of gram negative bacteria and gram positive bacteria varied from 0% to 100% in our study. This is different when compared to a previous study which reported a higher resistance in gram negative bacteria (20-100%) as compared to gram positive bacteria (23.5%-58.8%).[12] Among the *Klebsiella pneumoniae* isolates high level sensitivity was shown by colistin 100% followed by tigecycline 88.3%, imipenem 64.7% and meropenem 41.2%. Singh et al, 2014 reported 100% and 71.4% sensitivity for imipenem and meropenem respectively each.[8] *Eschericia coli* showed high level sensitivity to colistin and tigecycline 100%, followed by ertapenem 80%, amikacin and gentamicin 70%. The sensitivity of gentamicin in our study was much higher as compared to an earlier Indian study 35%.[13]

Differences in antimicrobial resistant pattern in different studies may be due to circulation of different strains in different regions at different times.

Among the yeast isolates *Candida tropicalis* was isolated in two blood culture samples. Both the isolates were 100% sensitive to fluconozole, voriconazole, caspofungi, micafungin, amphotericin-B, and flucytosin. However, studies from different parts of India reported the emergence of *nonalbicans Candida* and resistant to widely used antifungal agents.[14,15]

CONCLUSION

Coagulase negative *staphylococcus* and *Klebsiella pneumoniae* were the predominant isolates of the study. High level multidrug resistance was observed in both GPC and GNB. Tigecycline and colistin remains the choice of antibiotics for gram-negative bacilli. Gentamicin, linezolid, vancomycin and tigecycline are the choice of antibiotics for gram positive cocci. Good antibiotic policy and strict hospital infection control measures may help to curb the emergence of multidrug resistant pathogens. There is a need for continuous monitoring and updating the BSI isolates and their antimicrobial patterns for an early effective approach to treatment.

Prevalence of *exoT* Gene in *Pseudomonas aeruginosa* Isolated from Various Clinical Samples: A Cross-sectional Study

JAGANNATH DNYANOBA ANDHALE[1], M ANJANEYA SWAMY[2], RN MISRA[3]

ABSTRACT

Introduction: *Pseudomonas aeruginosa (P.aeruginosa)* is one of the most frequently co-infecting bacteria reported. Development of drug resistance, biofilm formation, cell associated factors make the *P.aeruginosa* more virulent. Type III secretion system controls expression of genes. *P.aeruginosa* chromosome harbours *exoT, exoS, exoU*, and *exoY* virulent genes. Gene *exoT* plays an important role in causation of infection. The identification of virulent markers of pathogens for identification of acute and chronic infections at early stage remains a critical area and still need large research.

Aim: To study the prevalence of *exoT* gene encoding exotoxin T in *P.aeruginosa* from clinical samples.

Materials and Methods: A descriptive cross-sectional research was conducted during January 2015 to March 2016 at the Department of Microbiology in Dr. D.Y. Patil Medical College, Pimpri, Pune, Maharashtra, India. Various clinical samples were processed using standard laboratory methods. The statistical analysis was done by using Chi-square test. Strains of *P.aeruginosa* isolated from various clinical samples were identified using standard laboratory methods, and *exoT* gene was detected by Polymerase Chain Reaction (PCR) and gel electrophoresis technique.

Results: Out of 30 strains of *P. aeruginosa*, 20 (66.67%) were isolated from male and 10 (33.33%) from female patients. Most of them belonged to the age group 41-60 years (46.67%). The *exoT* gene occurred in 20/30 (66.67%) isolates of *P.aeruginosa*, while 10/30 (33.33 %) showed negative amplification results. Out of 20 *exoT* genes in *P.aeruginosa*, 17/20 (85%) were detected from male and 3/10 (15%) from female patients.

Conclusion: Gene *exoT* of *P. aeruginosa* plays the crucial role in causation of disease. It is concluded that *exoT* gene can be a notable virulent element expressed by 66.67% of *P.aeruginosa* clinical isolates. The proven role of *exoT* virulence gene in the pathogenicity of *P.aeruginosa* would help in understanding the prognosis of *Pseudomonas* infection and designing an effective treatment and vaccine against the *Pseudomonas* infections to prevent them.

Keywords: Exotoxin T, Gram negative bacteria, Polymerase chain reaction

INTRODUCTION

Pseudomonas aeruginosa (*P.aeruginosa*) is an actively motile, biofilm forming Gram negative human opportunistic pathogen. It exhibits multidrug resistance and is widely connected with hospital acquired infections [1]. They are resistant to multiple antibiotics due to acquired or inherent determinants. It can cause acute and chronic infections [2]. *P.aeruginosa* causes serious infections such as endocarditis, pneumonia, septicaemia, wound infections, cystitis [3], blood stream infections, urinary tract infection and surgical site infections [4]. Biofilm formation, development of drug resistance, various secreted toxins, proteases, pyocyanin, exotoxins and different cell associated factors make *P.aeruginosa* more virulent [5]. *P.aeruginosa* has the ability to colonise the respiratory tract and is one of the members of normal flora of nasopharynx [6]. *P.aeruginosa* infections are more frequently observed in cystic fibrosis and in weakened immune patients. In a recent study, researcher documented *P.aeruginosa* as a common co-infecting pathogen in patients [7].

P.aeruginosa continues to exist in different environmental states because of different virulence factors and metabolic properties [8]. Toxins are released by passive transport from the cells secreted by one of the three secretion systems namely, Type I Secretion System (T1SS), Type II Secretion System (T2SS) and Type III Secretion System (T3SS). Type III secretary system plays a key role in determining virulence [9]. The Gram negative bacteria have a complex T3SS which is an essential machinery of *P.aeruginosa* to inject exotoxin T (*exoT*), exotoxin S (*exoS*) and exotoxin U (*exoU*) virulence factors directly into host cells [10] and can evoke different responses from the host suitable for spreading of infection [11]. Exotoxin produced during release and escape of pathogen mainly attacks host kinases and is responsible for adhesion, phagocytosis, with spreading type of infection from lung to the liver in experimental animal [9,12].

Very few researchers in India have focussed on *exoT* gene encoding exotoxin T, virulence factor of T3SS of *P.aeruginosa*. In previous similar study in India, the researcher documented 84% prevalence of *exoT* gene in *P.aeruginosa* strains obtained from various clinical samples [13]. Keeping these facts in mind, this study was designed to study the prevalence of *exoT* gene in *P.aeruginosa* obtained from different clinical samples in a tertiary care hospital.

MATERIALS AND METHODS

Present descriptive cross-sectional research was conducted during January 2015 to March 2016 at the Department of Microbiology in Dr DY Patil Medical College, Hospital and Research Centre, Pimpri, Pune, Maharashtra, India. Different clinical samples (pus, urine, sputum, blood and body fluids) were received from various wards irrespective of age and gender for routine culture and sensitivity tests. The isolates were processed and confirmed *P.aeruginosa* strains were screened for detection of *exoT* gene by PCR and gel electrophoresis techniques. The study was done after approval from Institutional Ethical Committee of Dr DY Patil Medical College, Hospital and Research Centre, Pimpri, Pune, Maharashtra, India.

Inclusion criteria: Samples showing *P.aeruginosa* as single causative agent of infection were included in this study. Total 30 strains were included in this research study.

Exclusion criteria: Samples showing mixed growth were excluded from this study.

Isolation and identification of *P.aeruginosa*: All clinical samples were inoculated onto MacConkey agar, Nutrient agar and Blood agar plates. Inoculated plates were incubated at 37ºC for 24 hours. After obtaining the growth, *P.aeruginosa* was identified by studying colony characteristics, production of pyocyanin pigments, grape like odour, growth at 42ºC, motility test, Gram staining, and positive oxidase, citrate, and catalase tests [14].

Extraction of DNA: For the detection of *exoT* gene, chromosomal DNA from the 30 clinical strains of *P.aeruginosa* clinical isolates was extracted and DNA purification was carried out using a commercial available DNA extraction kit (Ganeaid-Presto™ Mini gDNA bacteria Kit) as indicated by manufacturer's instructions.

Polymerase Chain Reaction (PCR): The sequences of the primers used in PCR for detection of *exoT* gene and its molecular weight are shown in [Table/Fig-1] [15,16].

Gene	Primer sequence	Amplicon size	Length (bp)
exoT	Forward 5'-AATCGCCGTCCAACTGCATGCG-3'	22	152
	Reverse 5'-TGTTCGCCGAGGTACTGCTC-3'	20	

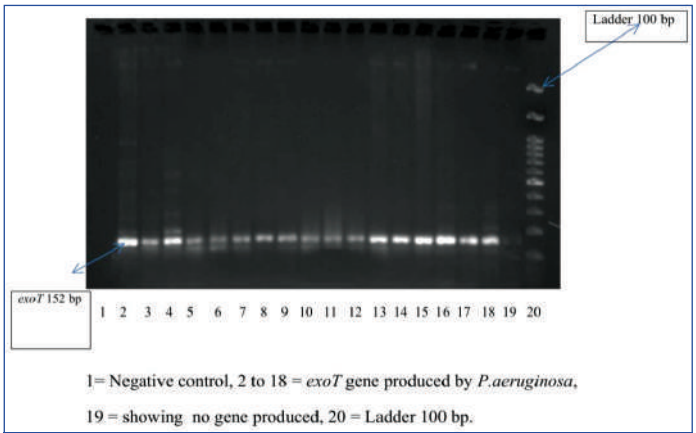
[Table/Fig-1]: The Primer sequence used for the detection of exoT genes.

For all PCRs, the DNA extracted from *P.aeruginosa* under study was used as templates. PCRs were carried out in 25 µL mixture containing 12.5 µL mastermix (Geneaid-Presto™Mini gDNA bacteria Kit), 1.5 µL forward primers, 1.5 µL reverse primers, 2.0 µL DNA template and 7.5 µL distilled water [Table/Fig-2].

Gene	Initial De-naturation	No.of Cycles	Denaturation in Each Cycle	Anneal-ing	Primer Extention	Final Extention
exoT	95ºC, 2 min	36	95ºC, 30 sec	58ºC,30 sec	72ºC, 30 sec	72ºC,5 min

[Table/Fig-2]: Polymerase Chain Reaction (PCR) conditions.

Gel electrophoresis: Electrophoresis was done using PCR products of *P.aeruginosa*.To prepare agarose gel, 2% agarose with ethidium bromide was used, as it shows clear resolution for small fragments. The quantity of agarose used for a gel preparation was around 250 mL. Images of PCR products were detected using transillumator by UV illumination is shown [Table/Fig-3]. PCR products were estimated by comparing with the 100bp DNA molecular size markers [17].



[Table/Fig-3]: Showing gel electrophoresis and amplification products of virulence gene (*exoT*) of *Pseudomonas aeruginosa* clinical isolates.

STATISTICAL ANALYSIS

The statistical analysis was done by using Chi-square test on line by graphpad prism 9.2.0.332. The calculated p-value was 0.0093 which is significant.

RESULTS

Out of 30 strains of *P.aeruginosa*, 20 (66.67%) were isolated from male and 10 (33.33%) from female patients. Most of the subjects belonged to 41-60 years of age group (46.67%). Out of 20 *exoT* genes in *P.aeruginosa*, 17/20 (85%) were detected from male and 3/10 (15%) from female patients [Table/Fig-4].

Age group (years)	Male	Female
0-20	00	00
21-40	02	01
41-60	12	02
61-80	03	00
Total	17	03

[Table/Fig-4]: Age and gender wise distribution of prevalence of *exoT* gene in *P.aeruginosa* (N=20).
Chi square 6.769, df-1, p-value=0.0093, p-value is statistically significant

The prevalence of *exoT* gene was 66.67%. Out of 30 strains of *P.aeruginosa* clinical isolates, 20 (66.67%) showed amplification of *exoT* gene and 10 (33.33%) strains showed negative amplification [Table/Fig-5].

DISCUSSION

P.aeruginosa is one of the major and well identified nosocomial pathogen. It has capability to survive and multiply with minimal nutrients. It can cause severe infection in hospitalised patients. *P.aeruginosa* is one of the most common co-infecting pathogen and exotoxin T is virulence factor that make *P.aeruginosa* more virulent for host cells. This descriptive research study was undertaken to detect *exoT* gene encoding exotoxin T in *P.aeruginosa* clinical isolates. T3SS is a basic and important weapon of *P.aeruginosa* and several other Gram negative

organisms for survival and causation of disease. The T3SS is a needle like sharp tiny machine that carry and deliver effector proteins (exotoxins) directly into targeted cells of the host to start disease. These delivered exotoxin precipitate and continue progress of infection by changing normal functions of target cells, such as constant movement of network of protein filaments and microtubules in the cytoplasm, reactions of cells to inflammatory stimuli, signalling pathways and secretory trafficking [18]. T3SS complex cellular nano machine is a key weapon of several pathogenic Gram negative bacteria which works in a systematic planned mode of action and can alter the target cell in number in irregular manner. T3SS has gradually developed because of the pressure of the survival within infected cells.

Virulence factors injected by T3SS into host cells play important role for *P.aeruginosa* to be more virulent [19,20]. The gene *exoT*, modify the actin cytoskeleton, inhibit migration and multiplication of cell. Exotoxin T prevents adhesion, phagocytosis, excessive multiplication and stop epithelial barrier that help *P.aeruginosa* to cause spread type of infections [21]. Gene *exoT* is an important virulence gene encoding exoenzyme T. Therefore, detection of *exoT* gene is important while determining pathogenicity of *P.aeruginosa* in different type of infections.

In this research study, authors aimed to determine the prevalence of *exoT* virulent gene in 30 strains of *P.aeruginosa* isolated from various clinical samples in a Tertiary Care Hospital. PCR and gel electrophoresis technique was used for the detection of *exoT* gene in *P.aeruginosa* under study. In this study, the prevalence of *exoT* gene was 66.67%. Out of 30 strains of *P.aeruginosa* clinical isolates from the different clinical conditions, 20 (66.67%) detected *exoT* gene in all spreading type of infections caused by *P.aeruginosa. P.aeruginosa* isolates from pus (61.11%), sputum (100%), urine (80%) and bodyfluids (100%) samples showed presence *exoT* gene. Out of 30, 10 (33.33%) strains were found to be negative for *exoT* gene.

In other similar study in southern India, the prevalence of *exoT* was recorded as 84% [13]. Many researches all over the world studied the prevalence of *exoT* genes as an epidemiological marker in pathogenic *P.aeruginosa* causing different type of infections. The prevalence of *exoT* genes has been found to be variable in *P. aeruginosa* isolates obtained from different infections in the world. Prevalence of *exoT* gene recorded in Iran was 36.27% [22] and in Egypt and Romania, prevalence of *exoT* in *P.aeruginosa* clinical isolates were recorded as 100% [12,23].

Role of *exoT* gene is crucial in the causation of spreading type infections. T3SS virulence factors are responsible for seriousness of the infections with raised death rate [24]. The proven role of *exoT* virulence genes in the pathogenicity of *P.aeruginosa* would help in understanding the prognosis of *Pseudomonas* infections and designing an effective vaccine against the pseudomonas infections to prevent them. This may help in epidemiological study, deciding the treatment course for the infections caused by *P.aeruginosa*. These findings may help in identifying virulent gene targets for immune intervention which could regulate the severity of the host response and its effect on impairment caused by *P.aeruginosa*.

The identification of virulent markers of pathogens for identification of acute and chronic infections at early stage remains a critical area and still need large research. Such type of research studies and findings facilitate the prevention of infections caused by bacteria and can be very useful to control the *Pseudomonas* infections.

Limitation(s)

All the *P.aeruginosa* strains under study were obtained from In Patient Department (IPD) only. Therefore, prevalence of *exoT* gene in *P.aeruginosa* could not be studied in Out Patient Department (OPD) patient. Larger sample size of both IPD and OPD patients would have provided better status of prevalence of *exoT* virulent gene marker as well as difference and significance.

CONCLUSION(S)

Gene *exoT* encoding ExotoxinT plays a very crucial role in the causation of disease. The proven role of *exoT* virulence genes in the pathogenicity of *P.aeruginosa* would help in understanding the prognosis of *Pseudomonas* infections and designing an effective vaccine against the *Pseudomonas* infections to prevent them. This may help in epidemiological study, deciding the treatment course for the infections caused by *P.aeruginosa*. In future trends in diagnostic microbiology, focus should be on development of rapid tests required for detection of virulence factors which are important epidemiological markers apart from identification and antimicrobial susceptibility tests.

Prevalence of *exoT* Gene in *Pseudomonas aeruginosa* Isolated from Various Clinical Samples: A Cross-sectional Study

JAGANNATH DNYANOBA ANDHALE[1], M ANJANEYA SWAMY[2], RN MISRA[3]

ABSTRACT

Introduction: *Pseudomonas aeruginosa (P.aeruginosa)* is one of the most frequently co-infecting bacteria reported. Development of drug resistance, biofilm formation, cell associated factors make the *P.aeruginosa* more virulent. Type III secretion system controls expression of genes. *P.aeruginosa* chromosome harbours *exoT, exoS, exoU*, and *exoY* virulent genes. Gene *exoT* plays an important role in causation of infection. The identification of virulent markers of pathogens for identification of acute and chronic infections at early stage remains a critical area and still need large research.

Aim: To study the prevalence of *exoT* gene encoding exotoxin T in *P.aeruginosa* from clinical samples.

Materials and Methods: A descriptive cross-sectional research was conducted during January 2015 to March 2016 at the Department of Microbiology in Dr. D.Y. Patil Medical College, Pimpri, Pune, Maharashtra, India. Various clinical samples were processed using standard laboratory methods. The statistical analysis was done by using Chi-square test. Strains of *P.aeruginosa* isolated from various clinical samples were identified using standard laboratory methods, and *exoT* gene was detected by Polymerase Chain Reaction (PCR) and gel electrophoresis technique.

Results: Out of 30 strains of *P. aeruginosa*, 20 (66.67%) were isolated from male and 10 (33.33%) from female patients. Most of them belonged to the age group 41-60 years (46.67%). The *exoT* gene occurred in 20/30 (66.67%) isolates of *P.aeruginosa*, while 10/30 (33.33 %) showed negative amplification results. Out of 20 *exoT* genes in *P.aeruginosa*, 17/20 (85%) were detected from male and 3/10 (15%) from female patients.

Conclusion: Gene *exoT* of *P. aeruginosa* plays the crucial role in causation of disease. It is concluded that *exoT* gene can be a notable virulent element expressed by 66.67% of *P.aeruginosa* clinical isolates. The proven role of *exoT* virulence gene in the pathogenicity of *P.aeruginosa* would help in understanding the prognosis of *Pseudomonas* infection and designing an effective treatment and vaccine against the *Pseudomonas* infections to prevent them.

Keywords: Exotoxin T, Gram negative bacteria, Polymerase chain reaction

INTRODUCTION

Pseudomonas aeruginosa (*P.aeruginosa*) is an actively motile, biofilm forming Gram negative human opportunistic pathogen. It exhibits multidrug resistance and is widely connected with hospital acquired infections [1]. They are resistant to multiple antibiotics due to acquired or inherent determinants. It can cause acute and chronic infections [2]. *P.aeruginosa* causes serious infections such as endocarditis, pneumonia, septicaemia, wound infections, cystitis [3], blood stream infections, urinary tract infection and surgical site infections [4]. Biofilm formation, development of drug resistance, various secreted toxins, proteases, pyocyanin, exotoxins and different cell associated factors make *P.aeruginosa* more virulent [5]. *P.aeruginosa* has the ability to colonise the respiratory tract and is one of the members of normal flora of nasopharynx [6]. *P.aeruginosa* infections are more frequently observed in cystic fibrosis and in weakened immune patients. In a recent study, researcher documented *P.aeruginosa* as a common co-infecting pathogen in patients [7].

P.aeruginosa continues to exist in different environmental states because of different virulence factors and metabolic properties [8]. Toxins are released by passive transport from the cells secreted by one of the three secretion systems namely, Type I Secretion System (T1SS), Type II Secretion System (T2SS) and Type III Secretion System (T3SS). Type III secretary system plays a key role in determining virulence [9]. The Gram negative bacteria have a complex T3SS which is an essential machinery of *P.aeruginosa* to inject exotoxin T (*exoT*), exotoxin S (*exoS*) and exotoxin U (*exoU*) virulence factors directly into host cells [10] and can evoke different responses from the host suitable for spreading of infection [11]. Exotoxin produced during release and escape of pathogen mainly attacks host kinases and is responsible for adhesion, phagocytosis, with spreading type of infection from lung to the liver in experimental animal [9,12].

Very few researchers in India have focussed on *exoT* gene encoding exotoxin T, virulence factor of T3SS of *P.aeruginosa*. In previous similar study in India, the researcher documented 84% prevalence of *exoT* gene in *P.aeruginosa* strains obtained from various clinical samples [13]. Keeping these facts in mind, this study was designed to study the prevalence of *exoT* gene in *P.aeruginosa* obtained from different clinical samples in a tertiary care hospital.

MATERIALS AND METHODS

Present descriptive cross-sectional research was conducted during January 2015 to March 2016 at the Department of Microbiology in Dr DY Patil Medical College, Hospital and Research Centre, Pimpri, Pune, Maharashtra, India. Different clinical samples (pus, urine, sputum, blood and body fluids) were received from various wards irrespective of age and gender for routine culture and sensitivity tests. The isolates were processed and confirmed *P.aeruginosa* strains were screened for detection of *exoT* gene by PCR and gel electrophoresis techniques. The study was done after approval from Institutional Ethical Committee of Dr DY Patil Medical College, Hospital and Research Centre, Pimpri, Pune, Maharashtra, India.

Inclusion criteria: Samples showing *P.aeruginosa* as single causative agent of infection were included in this study. Total 30 strains were included in this research study.

Exclusion criteria: Samples showing mixed growth were excluded from this study.

Isolation and identification of *P.aeruginosa*: All clinical samples were inoculated onto MacConkey agar, Nutrient agar and Blood agar plates. Inoculated plates were incubated at 37ºC for 24 hours. After obtaining the growth, *P.aeruginosa* was identified by studying colony characteristics, production of pyocyanin pigments, grape like odour, growth at 42ºC, motility test, Gram staining, and positive oxidase, citrate, and catalase tests [14].

Extraction of DNA: For the detection of *exoT* gene, chromosomal DNA from the 30 clinical strains of *P.aeruginosa* clinical isolates was extracted and DNA purification was carried out using a commercial available DNA extraction kit (Ganeaid-Presto™ Mini gDNA bacteria Kit) as indicated by manufacturer's instructions.

Polymerase Chain Reaction (PCR): The sequences of the primers used in PCR for detection of *exoT* gene and its molecular weight are shown in [Table/Fig-1] [15,16].

Gene	Primer sequence	Amplicon size	Length (bp)
exoT	Forward 5'-AATCGCCGTCCAACTGCATGCG-3'	22	152
	Reverse 5'-TGTTCGCCGAGGTACTGCTC-3'	20	

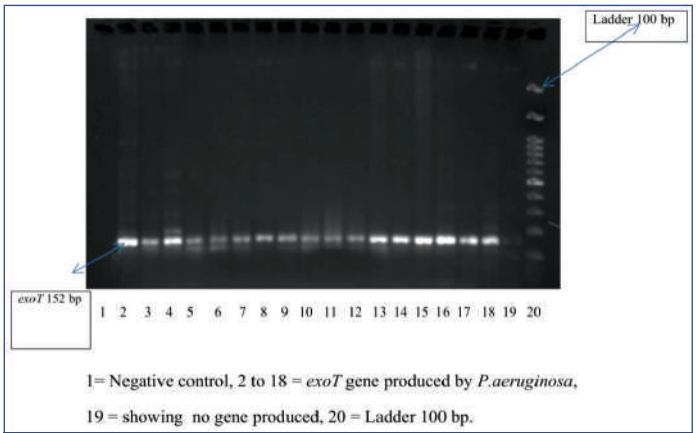
[Table/Fig-1]: The Primer sequence used for the detection of exoT genes.

For all PCRs, the DNA extracted from *P.aeruginosa* under study was used as templates. PCRs were carried out in 25 µL mixture containing 12.5 µL mastermix (Geneaid-Presto™Mini gDNA bacteria Kit), 1.5 µL forward primers, 1.5 µL reverse primers, 2.0 µL DNA template and 7.5 µL distilled water [Table/Fig-2].

Gene	Initial De-naturation	No.of Cycles	Denaturation in Each Cycle	Anneal-ing	Primer Extention	Final Extention
exoT	95ºC, 2 min	36	95ºC, 30 sec	58ºC,30 sec	72ºC, 30 sec	72ºC,5 min

[Table/Fig-2]: Polymerase Chain Reaction (PCR) conditions.

Gel electrophoresis: Electrophoresis was done using PCR products of *P.aeruginosa*.To prepare agarose gel, 2% agarose with ethidium bromide was used, as it shows clear resolution for small fragments. The quantity of agarose used for a gel preparation was around 250 mL. Images of PCR products were detected using transillumator by UV illumination is shown [Table/Fig-3]. PCR products were estimated by comparing with the 100bp DNA molecular size markers [17].



[Table/Fig-3]: Showing gel electrophoresis and amplification products of virulence gene (*exoT*) of *Pseudomonas aeruginosa* clinical isolates.

STATISTICAL ANALYSIS

The statistical analysis was done by using Chi-square test on line by graphpad prism 9.2.0.332. The calculated p-value was 0.0093 which is significant.

RESULTS

Out of 30 strains of *P.aeruginosa*, 20 (66.67%) were isolated from male and 10 (33.33%) from female patients. Most of the subjects belonged to 41-60 years of age group (46.67%). Out of 20 *exoT* genes in *P.aeruginosa*, 17/20 (85%) were detected from male and 3/10 (15%) from female patients [Table/Fig-4].

Age group (years)	Male	Female
0-20	00	00
21-40	02	01
41-60	12	02
61-80	03	00
Total	17	03

[Table/Fig-4]: Age and gender wise distribution of prevalence of *exoT* gene in *P.aeruginosa* (N=20).
Chi square 6.769, df-1, p-value=0.0093, p-value is statistically significant

The prevalence of *exoT* gene was 66.67%. Out of 30 strains of *P.aeruginosa* clinical isolates, 20 (66.67%) showed amplification of *exoT* gene and 10 (33.33%) strains showed negative amplification [Table/Fig-5].

DISCUSSION

P.aeruginosa is one of the major and well identified nosocomial pathogen. It has capability to survive and multiply with minimal nutrients. It can cause severe infection in hospitalised patients. *P.aeruginosa* is one of the most common co-infecting pathogen and exotoxin T is virulence factor that make *P.aeruginosa* more virulent for host cells. This descriptive research study was undertaken to detect *exoT* gene encoding exotoxin T in *P.aeruginosa* clinical isolates. T3SS is a basic and important weapon of *P.aeruginosa* and several other Gram negative

organisms for survival and causation of disease. The T3SS is a needle like sharp tiny machine that carry and deliver effector proteins (exotoxins) directly into targeted cells of the host to start disease. These delivered exotoxin precipitate and continue progress of infection by changing normal functions of target cells, such as constant movement of network of protein filaments and microtubules in the cytoplasm, reactions of cells to inflammatory stimuli, signalling pathways and secretory trafficking [18]. T3SS complex cellular nano machine is a key weapon of several pathogenic Gram negative bacteria which works in a systematic planned mode of action and can alter the target cell in number in irregular manner. T3SS has gradually developed because of the pressure of the survival within infected cells.

Virulence factors injected by T3SS into host cells play important role for *P.aeruginosa* to be more virulent [19,20]. The gene *exoT*, modify the actin cytoskeleton, inhibit migration and multiplication of cell. Exotoxin T prevents adhesion, phagocytosis, excessive multiplication and stop epithelial barrier that help *P.aeruginosa* to cause spread type of infections [21]. Gene *exoT* is an important virulence gene encoding exoenzyme T. Therefore, detection of *exoT* gene is important while determining pathogenicity of *P.aeruginosa* in different type of infections.

In this research study, authors aimed to determine the prevalence of *exoT* virulent gene in 30 strains of *P.aeruginosa* isolated from various clinical samples in a Tertiary Care Hospital. PCR and gel electrophoresis technique was used for the detection of *exoT* gene in *P.aeruginosa* under study. In this study, the prevalence of *exoT* gene was 66.67%. Out of 30 strains of *P.aeruginosa* clinical isolates from the different clinical conditions, 20 (66.67%) detected *exoT* gene in all spreading type of infections caused by *P.aeruginosa. P.aeruginosa* isolates from pus (61.11%), sputum (100%), urine (80%) and bodyfluids (100%) samples showed presence *exoT* gene. Out of 30, 10 (33.33%) strains were found to be negative for *exoT* gene.

In other similar study in southern India, the prevalence of *exoT* was recorded as 84% [13]. Many researches all over the world studied the prevalence of *exoT* genes as an epidemiological marker in pathogenic *P.aeruginosa* causing different type of infections. The prevalence of *exoT* genes has been found to be variable in *P. aeruginosa* isolates obtained from different infections in the world. Prevalence of *exoT* gene recorded in Iran was 36.27% [22] and in Egypt and Romania, prevalence of *exoT* in *P.aeruginosa* clinical isolates were recorded as 100% [12,23].

Role of *exoT* gene is crucial in the causation of spreading type infections. T3SS virulence factors are responsible for seriousness of the infections with raised death rate [24]. The proven role of *exoT* virulence genes in the pathogenicity of *P.aeruginosa* would help in understanding the prognosis of *Pseudomonas* infections and designing an effective vaccine against the pseudomonas infections to prevent them. This may help in epidemiological study, deciding the treatment course for the infections caused by *P.aeruginosa*. These findings may help in identifying virulent gene targets for immune intervention which could regulate the severity of the host response and its effect on impairment caused by *P.aeruginosa*.

The identification of virulent markers of pathogens for identification of acute and chronic infections at early stage remains a critical area and still need large research. Such type of research studies and findings facilitate the prevention of infections caused by bacteria and can be very useful to control the *Pseudomonas* infections.

Limitation(s)

All the *P.aeruginosa* strains under study were obtained from In Patient Department (IPD) only. Therefore, prevalence of *exoT* gene in *P.aeruginosa* could not be studied in Out Patient Department (OPD) patient. Larger sample size of both IPD and OPD patients would have provided better status of prevalence of *exoT* virulent gene marker as well as difference and significance.

CONCLUSION(S)

Gene *exoT* encoding ExotoxinT plays a very crucial role in the causation of disease. The proven role of *exoT* virulence genes in the pathogenicity of *P.aeruginosa* would help in understanding the prognosis of *Pseudomonas* infections and designing an effective vaccine against the *Pseudomonas* infections to prevent them. This may help in epidemiological study, deciding the treatment course for the infections caused by *P.aeruginosa*. In future trends in diagnostic microbiology, focus should be on development of rapid tests required for detection of virulence factors which are important epidemiological markers apart from identification and antimicrobial susceptibility tests.

ABSTRACT

Background: Anemia reported during pregnancy is a burdensome public health problem all around the world, problem is vast among developing¬ countries. Women during pregnancy are more prone for developing anemia not only because of increased iron demand and its poor bioavailability along with hemodilution physiological increase in plasma volume (physiological increase in plasma volume) which acts synergistically. **Material & Methods:** In the present prospective observational study 400 Pregnant women were enrolled from outdoor, antenatal clinic and from ward by simple random sampling. Clearance from Institutional Ethics Committee was taken before start of study. Written informed consent was taken from each study participant. **Results:** In the present study out of total primigravida 118 (54.6%) had no anemia, 72 (33.3%) females had mild anemia, 26 (12%) females had moderate anemia and there were no cases of severe anemia in this group. Among the group of birth interval of less than two years, there were no cases of no anemia, 42 (45.6%) of pregnant women had mild anemia, 38 (41.4%) of pregnant women had moderate anemia and 12 (13%) of pregnant women had severe anemia. Among the group of birth interval of more than two years, there were no cases of no anemia, 32 (34.8%) of pregnant women had mild anemia, 58 (63.1%) of pregnant women had moderate anemia and 2 (2.2%) of pregnant women had severe anemia. These differences in burden of anemia was statistically highly significant (p value < 0.001). **Conclusions:** The magnitude and burden of anemia is very high and the population living among rural areas were at high risk of developing anemia. We found statistically significant correlation of anemia with birth interval and reported that the burden of severe anemia was higher among pregnant women who had birth interval of less than two years.

Key words: Anemia, Pregnancy, Birth interval.

INTRODUCTION

The word "Anemia" is a Greek word which means an- 'not', haima- 'blood', refers to 'no blood'. Anemia itself is not a disease but a precursor and predictive sign of the presence of disease. Anemia reported during pregnancy is a burdensome public health problem all around the world, problem is vast among developing¬ countries. Women during pregnancy are more prone for developing anemia not only because of increased iron demand and its poor bioavailability along with hemodilution physiological increase in plasma volume (physiological increase in plasma volume) which acts synergistically (1).

Anemia is among the strongest associated factor which decide the fate and outcome of pregnancy. Since anemia is act as silent epidemic, it is as harmful and compelling as infectious diseases epidemics. It was reported that anemia contributes for more than 20% of maternal deaths worldwide (2). Among these maternal deaths more than 50% of the maternal deaths occur among South Asian countries. India contributes for 80% of maternal death occurred among South Asian countries (3). There are several risk factors associated with morbidity and mortality among pregnant women such as postpartum hemorrhage, abortion, , low birth weight baby, still birth, high perinatal mortality, undercurrent infection, infant mortality and maternal mortality.(4)

Regarding this context of combating anaemia during pregnancy, with far reaching benefits in terms of safe motherhood and healthier future generations, an attempt has been made to know the magnitude of anaemia among urban and rural pregnant women along with to study the relationship between anaemia and contributory factor of birth interval to meet the challenge of protecting maternal and neonatal health.

Material & Methods

The present prospective study was conducted at department of obstetrics and gynaecology of Geetanjali Medical college and hospital, Udaipur. The study duration was of one year from June 2015 to July 2016. A sample size of 400 was calculated at 95% confidence interval at 10% acceptable margin of error by epi info software version 7.2. Pregnant women were enrolled from outdoor, antenatal clinic and from ward by simple random sampling. Clearance from Institutional Ethics Committee was taken before start of study. Written informed consent was taken from each study participant.

The data were collected by predesigned, multiple response type of questionnaire from each pregnant woman (above 18 years of age and beyond 12 weeks of amenorrhea) after taking the written consent. The questionnaire was address on the topics of anaemia and our study variables birth intervals and geographical living areas. Data analysis was carried out using SPSS v22. All tests were done at alpha (level significance) of 5%; means a significant association present if p value was less than 0.05.

RESULT

In the present study, we enrolled 400 pregnant women who were classified in two major groups according to the residential area. Women who had been pregnant first time and were enrolled for the study designated in a group of birth interval zero. We classified other two groups as birth interval less than two years and birth interval of more than two years between two consecutive pregnancies. There were 216 females in the group of birth interval zero, 92 females in the birth interval of less than two years and 92 females in the group of birth interval of more than two years. Among primigravida 118 (54.6%) had no anaemia, 72 (33.3%) females had mild anemia, 26 (12%) females had moderate anemia and there were no cases of severe anemia in this group. Among the group of birth interval of less than two years, there were no cases of no anemia, 42 (45.6%) of pregnant women had mild anemia, 38 (41.4%) of pregnant women had moderate anemia and 12 (13%) of pregnant women had severe anemia. Among the group of birth interval of more than two years, there were no cases of no anemia, 32 (34.8%) of pregnant women had mild anemia, 58 (63.1%) of pregnant women had moderate anemia and 2 (2.2%) of pregnant women had severe anemia. These differences in burden of anemia were statistically highly significant (p value < 0.001). [Table 1]

Table 1: Relationship between birth interval and severity of anaemia

Birth interval (years)	Severity				
	No anaemia	Mild anaemia	Moderate anaemia	Severe anaemia	Total
None	118 (54.6%)	72 (33.3%)	26 (12%)	0 (0%)	216 (100%)
Less than 2	0 (0%)	42 (45.6%)	38 (41.4%)	12 (13%)	92 (100%)
More than 2	0 (0%)	32 (34.8%)	58 (63.1%)	2 (2.2%)	92 (100%)
Total	118 (29.5%)	146 (36.5%)	122 (30.5%)	14 (3.5%)	400 (100%)
	$\chi^2 = 97.434$	df= 6	P< 0.001		

In the present study, among primigravida 118 (54.6%) who had no anaemia 74 were from urban area and 44 from rural area. Among 72 (33.3%) primigravida who had mild anemia 38 were from urban area and 34 from rural area and 26 (12%) primigravida who had moderate anemia 12 were from urban area and 14 from rural area. In the group of birth interval of less than two years, out of 42 (45.6%) of pregnant women who had mild anemia 22 were from urban area and 20 from rural area. Out of 38 (41.4%) of pregnant women who had moderate anemia 10 were from urban area and 28 from rural area. Out of 12 (13%) of pregnant women who had severe anemia were from rural areas. In the group of birth interval of more than two years, out of 32 (34.8%) of pregnant women had mild anemia 10 were from urban area and 22 from rural area. Out of 58 (63.1%) of pregnant women had moderate anemia 32 were from urban area and 26 from rural area. Out of 2 (2.2%) of pregnant women who had severe anemia both were from urban areas. This difference in burden of anemia was statistically highly significant (p value < 0.001). [Table2]

Table 2: Relationship between birth interval and severity of anaemia among urban and rural pregnant women

DISCUSSION

The present prospective study was conducted at the field practicing areas under department of obstetrics and gynaecology of our tertiary care hospital. The aim of present study was assessing the magnitude and burden of anaemia along in the correlation to birth intervals among two consecutive pregnancies. In the present study we enrolled 400 pregnant women from different urban and rural areas and further subdivided them into four subgroups of no anemia, mild anemia, moderate anemia and severe anemia.

In the present study the age of enrolled pregnant women was ranged from 19 to 38 years. The mean age of the enrolled pregnant women was 23.88 ± 3.66 years. There were no pregnant women in the present study who aged less than 19 years of age. In the present study the overall burden of anaemia was found to be 69.5% which was comparatively more among rural areas (76%) in comparison to the urban areas (63%) and difference in the burden of anaemia was statically significant ($p < 0.05$). The odds of anaemia were 1.4 times higher among rural areas than urban pregnant mothers. The results of present study were comparable and nearly similar to the results of surveys of India conducted by National Family Health Survey (NFHS-3) and another survey conducted by District Level Household Survey (DLHS-3). (5)(6) The results of present study were comparable and nearly similar to the study conducted by Toral M. Goswami et al among pregnant women in 2014 on anaemia status during pregnancy and effects of anemia on perinatal outcome.(7)

In the present study, there were 216 females in the group of birth interval zero, 92 females in the birth interval of less than two years and 92 females in the group of birth interval of more than two years. Among primigravida 118 (54.6%) had no anaemia, 72 (33.3%) females had mild anemia, 26 (12%) females had moderate anemia and there were no cases of severe anemia in this group. Among the group of birth interval of less than two years, there were no cases of no anemia, 42 (45.6%) of pregnant women had mild anemia, 38 (41.4%) of pregnant women had moderate anemia and 12 (13%) of pregnant women had severe anemia. Among the group of birth interval of more than two years, there were no cases of no anemia, 32 (34.8%) of pregnant women had mild anemia, 58 (63.1%) of pregnant women had moderate anemia and 2 (2.2%) of pregnant women had severe anemia. This difference in burden of anemia was statistically highly significant (p value < 0.001). A study by Abbasi RM et al showed found similar results with anemia and birth interval. (8)

In the present study, among primigravida 118 (54.6%) who had no anaemia 74 were from urban area and 44 from rural area. Among 72 (33.3%) primigravida who had mild anemia 38 were from urban area and 34 from rural area and 26 (12%) primigravida who had moderate anemia 12 were from urban area and 14 from rural area. In the group of birth interval of less than two years, out of 42 (45.6%) of pregnant women who had mild anemia 22 were from urban area and 20 from rural area. Out of 38 (41.4%) of pregnant women who had moderate anemia 10 were from urban area and 28 from rural area. Out of 12 (13%) of pregnant women who had severe anemia were from rural areas. In the group of birth interval of more than two years, out of 32 (34.8%) of pregnant women had mild anemia 10 were from urban area and 22 from rural area. Out of 58 (63.1%) of pregnant women had moderate anemia 32 were from urban area and 26 from rural area. Out of 2 (2.2%) of pregnant women who had severe anemia both were from urban areas. This difference in burden of anemia was statistically highly significant (p value < 0.001). Similar results were reported in a study by Vijay Kumar et al on s anaemia in pregnant women and found significant association of anaemia ($p < 0.05$) was found with birth interval. (9)

CONCLUSION

We concluded from the present study that the magnitude and burden of anemia is very high and the population living among rural areas were at high risk of developing anemia. We found statistically significant correlation of anemia with birth interval and reported that the burden of severe anemia was higher among pregnant women who had birth interval of less than two years.

ABSTRACT

Background: Anemia itself is not a disease but a precursor and predictive sign of the presence of disease. Anemia reported during pregnancy is a burdensome public health problem all around the world; problem is vast among developing countries. Women during pregnancy are more prone for developing anemia not only because of increased iron demand and its poor bioavailability along with hemodilution. **Material & Methods:** In the present prospective observational study 400 Pregnant women were enrolled from outdoor, antenatal clinic and from ward by simple random sampling. Clearance from Institutional Ethics Committee was taken before start of study. Written informed consent was taken from each study participant. **Results:** Among pregnant women with nil past abortions 108 (29.7%) had no anaemia, 140 (38.5%) females had mild anemia, 106 (29.1%) females had moderate anemia and 10 (2.7%) had severe anemia in this group. Among pregnant women with 1 abortions 10 (35.7%) had no anaemia, 6 (21.4%) females had mild anemia, 12 (42.9%) females had moderate anemia and there was no cases of severe anemia in this group. Among the group of pregnant women with 2 abortions, 4 (66.7%) of pregnant women had moderate anemia and 2 (33.3%) of pregnant women had severe anemia. Among the group of pregnant women with >2 abortions, 2 (100%) of pregnant women had severe anemia. (p value < 0.001) **Conclusions:** The magnitude and burden of anemia is very high and the population living among urban and rural areas both was at higher risk of developing anemia. We found statistically significant correlation of anemia with increasing number of abortions.

Key words: Anemia, Pregnancy, Abortion status.

INTRODUCTION

Anemia is among the strongest associated factor which decide the fate and outcome of pregnancy. Since anemia is act as silent epidemic, it is as harmful and compelling as infectious diseases epidemics. It was reported that anemia contributes for more than 20% of maternal deaths worldwide **(1)**. The word "Anemia" is a Greek word which means an- 'not', haima- 'blood', refers to 'no blood'. Anemia itself is not a disease but a precursor and predictive sign of the presence of disease.

Anemia reported during pregnancy is a burdensome public health problem all around the world; problem is vast among developing countries. Women during pregnancy are more prone for developing anemia not only because of increased iron demand and its poor bioavailability along with hemodilution physiological increase in plasma volume (physiological increase in plasma volume) which acts synergistically **(2)**. Among these maternal deaths more than 50% of the maternal deaths occur among South Asian countries. India

contributes for 80% of maternal death occurred among South Asian countries (3).

There are several risk factors associated with morbidity and mortality among pregnant women such as postpartum hemorrhage, abortion, , low birth weight baby, still birth, high perinatal mortality, undercurrent infection, infant mortality and maternal mortality (4). Regarding this context of combating anaemia during pregnancy, with far reaching benefits in terms of safe motherhood and healthier future generations, an attempt has been made to know the magnitude of anaemia among urban and rural pregnant women along with to study the relationship between anaemia and contributory factor of abortion status to meet the challenge of protecting maternal and neonatal health.

MATERIAL & METHODS

The present prospective study was conducted at department of obstetrics and gynaecology of Geetanjali Medical College and hospital, Udaipur. The study duration was of one year from June 2015 to July 2016. A sample size of 400 was calculated at 95% confidence interval at 10% acceptable margin of error by epi info software version 7.2. Pregnant women were enrolled from outdoor, antenatal clinic and from ward by simple random sampling. Clearance from Institutional Ethics Committee was taken before start of study. Written informed consent was taken from each study participant.

The data were collected by predesigned, multiple response type of questionnaire from each pregnant woman (above 18 years of age and beyond 12 weeks of amenorrhea) after taking the written consent. The questionnaire was address on the topics of anaemia and our study variables abortions status and geographical living areas. Data analysis was carried out using SPSS v22. All tests were done at alpha (level significance) of 5%; means a significant association present if p value was less than 0.05.

RESULT

In the present study we enrolled 400 pregnant women who were classified in two major groups according to the residential area. Women who never had abortions were enrolled in a group of abortion status zero. We classified other three groups further as abortion status one, two and more than two. There were 364 females in the group of abortion status zero, 28 females in the abortion status one, 6 females in the abortion status two and 2 females in the group abortion status of more than two. Among pregnant women with nil past abortions 108 (29.7%) had no anaemia, 140 (38.5%) females had mild anemia, 106 (29.1%) females had moderate anemia and 10 (2.7%) had severe anemia in this group. Among pregnant women with one past abortions 10 (35.7%) had no anaemia, 6 (21.4%) females had mild anemia, 12 (42.9%) females had moderate anemia and there was no cases of severe anemia in this group.

Among the group of pregnant women with two past abortions, there were no cases of no anemia and mild anemia, 4 (66.7%) of pregnant women had moderate anemia and 2 (33.3%) of pregnant women had severe anemia. Among the group of pregnant women with more than two past abortions, there were no cases of no anemia, mild anemia and moderate anemia and 2 (100%) of pregnant women had severe anemia. These differences in burden of anemia was statistically highly significant (p value < 0.001). [Table 1]

Table 1: Relationship between abortions and severity of anaemia

Abortions	Severity				
	No anaemia	Mild anaemia	Moderate anaemia	Severe anaemia	Total

In the present study Among pregnant women with nil past abortions 108 (29.7%) had no anaemia 68 were from urban area and 40 from rural area. Out of 140 (38.5%) females had mild anemia 66 were from urban area and 74 from rural area. Out of 106 (29.1%) females had moderate anemia 44 were from urban area and 62 from rural area and out 10 (2.7%) who had severe anemia in this group all belong to rural areas. Among pregnant women with one past abortions 10 (35.7%) had no anaemia 6 were from urban area and 4 from rural area. Out of 6 (21.4%) females who had mild anemia 4 were from urban area and 2 from rural area. Out of 12 (42.9%) females who had moderate anemia 6 were from urban area and 6 from rural area. Among the group of pregnant women with two past abortions, all 4 (66.7%) of pregnant women who had moderate anemia were from urban areas and 2 (33.3%) pregnant women who had severe anemia were from rural areas. Among the group of pregnant women with more than two past abortions, both the 2 pregnant women who had severe anemia were belong to urban areas. These differences in burden of anemia was statistically significant (p value < 0.05). [Table 2]

DISCUSSION

The present prospective study was conducted at the field practicing areas under department of obstetrics and gynecology of our tertiary care hospital. The aim of present study was assessing the magnitude and burden of anaemia along in the correlation to birth intervals among two consecutive pregnancies. In the present study we enrolled 400 pregnant women from different urban and rural areas and further subdivided them into four subgroups of no anemia, mild anemia, moderate anemia and severe anemia. In the present study the age of enrolled pregnant women was ranged from 19 to 38 years. The mean age of the enrolled pregnant women was 23.88 ± 3.66 years. There were no pregnant women in the present study who aged less than 19 years of age.

In the present study the overall burden of anaemia was found to be 69.5% which was comparatively more among rural areas (76%) in comparison to the urban areas (63%) and difference in the burden of anaemia was statically significant (p <0.05). The odds of anaemia were 1.4 times higher among rural areas than urban pregnant mothers. The results of present study were comparable and nearly similar to the results of surveys of India conducted by National Family Health Survey (NFHS-3) and another survey conducted by District Level Household Survey (DLHS-3).(5)(6) The results of present study were comparable and nearly similar to the study conducted by Toral M. Goswami et al among pregnant women in 2014 on anaemia status during pregnancy and effects of anemia on perinatal outcome.(7)

In the present study, there were 364 females in the group of abortion status zero, 28 females in the abortion status one, 6 females in the abortion status two and 2 females in the group abortion status of more than two. Among pregnant women with nil past abortions 108 (29.7%) had no anaemia, 140 (38.5%) females had mild anemia, 106 (29.1%) females had moderate anemia and 10 (2.7%) had severe anemia in this group. Among pregnant women with one past abortion 10 (35.7%) had no anaemia, 6 (21.4%) females had mild anemia, 12 (42.9%) females had moderate anemia and there was no cases of severe anemia in this group.

Among the group of pregnant women with two past abortions, there were no cases of no anemia and mild anemia, 4 (66.7%) of pregnant women had moderate anemia and 2 (33.3%) of pregnant women had severe anemia. Among the group of pregnant women with more than two past abortions, there were no cases of no anemia, mild anemia and moderate anemia and 2 (100%) of pregnant women had severe anemia. These differences in burden of anemia were statistically highly significant (p value < 0.001). Similar results were reported in a study done by Gautam VP et al among rural areas of Delhi and found similar correlation.(8)

In the present study Among pregnant women with nil past abortions 108 (29.7%) had no anaemia 68 were from urban area and 40 from rural area. Out of 140 (38.5%) females had mild anemia 66 were from urban area and 74 from rural area. Out of 106 (29.1%) females had moderate anemia 44 were from urban area and 62 from rural area and out 10 (2.7%) who had severe anemia in this group all belong to rural areas. Among pregnant women with one past abortions 10 (35.7%) had no anaemia 6 were from urban area and 4 from rural area. Out of 6 (21.4%) females who had mild anemia 4 were from urban area and 2 from rural area. Out of 12 (42.9%) females who had moderate anemia 6 were from urban area and 6 from rural area. Among the group of pregnant women with two past abortions, all 4 (66.7%) of pregnant women who had moderate anemia were from urban areas and 2 (33.3%) pregnant women who had severe anemia were from rural areas. Among the group of pregnant women with more than two past abortions, both the 2 pregnant women who had severe anemia were belong to urban areas. These differences in burden of anemia was statistically significant (p value < 0.05). Similar results were reported in a study conducted by RG Viveki et al on Anaemia and Its Epidemiological Determinants among Pregnant Women and found significant association of anaemia and its severity with two or more abortions. (9)

CONCLUSION

We concluded from the present study that the magnitude and burden of anemia is very high and the population living among urban and rural areas both were at higher risk of developing anemia. We found statistically significant correlation of anemia with increasing number of abortions and reported that the burden of severe anemia was higher among pregnant women who had more than two abortions.

Aims and Scope

International Journal of Medical and Biomedical Studies (IJMBS) is an international, peer-reviewed, open access, online journal dedicated to the rapid publication of full-length original research papers, short communications, invited reviews, Case studies and editorial commentary and news, Opinions & Perspectives and Book Reviews written at the invitation of the Editor in all areas of the Medical and Biomedical Studies.

International Journal of Medical and Biomedical Studies is an academic journal which aims to publish complete and reliable source of information in the field of medical research providing the fundamental knowledge for further research. IJMBS commits to publish the results of researches in medical practice, risk factors and preventive medicine, safety and effectiveness of treatments, and diagnostic tools that are used to treat any disease. Our journal aims to attract an international audience of Medicine professionals enthusiastic to the most updated and substantial medical progress through the full spectrum of medical research.

Medical Studies|| Biomedical Studies ||

Anatomy, Physiology, Anesthesia, Biochemistry, Molecular Biology, Cell biology, Genetics, Hematology, Pathology, Immunology, Microbiology, Virology, Parasitology, Surgery, Dental Sciences, Sports Physiology, Histopathology, Toxicology and all major disciplines of Biomedical Sciences, Pharmacokinetics, Molecular Drug Design, Phytochemistry, Toxicology, Biomedical Analysis, Clinical Research, Pharmacy Practice, Clinical and Hospital Pharmacy, Cell Biology, Genomics and Proteomics, Pharmacogenomics, Bioinformatics and Biotechnology, Agriculture, Herbal Medicine, Orthopaedics and all major disciplines of Medical and Biomedical Studies.

Articles are published as they are accepted and are freely available on the journal's website to facilitate rapid and broad dissemination of research findings to a global audience.

Top Reasons for publication with us

Quick Quality Review: The journal has strong international team of editors and reviewers, Rapid Decision and Publication

Abstract

Hyperbilirubinemia is a common disease that occurs especially in the first week of birth and is one of the most common causes of hospitalisation of the term and preterm infants in neonatal hospitals. It usually occurs on the second day of birth and is not usually harmful, and a self-limiting condition, where disease usually improves without treatment after reaching the normal amount of bilirubin but very high levels of bilirubin may lead to kernicterus as permanent brain damage. Several types of Bilirubinemia have been reported in neonates including physiological jaundice, pathological jaundice, jaundice due to breastfeeding or breast milk and hemolytic jaundice including three subtypes due to Rh factor incompatibility. Mothball use, a possible trigger for hemolysis in newborns with G6PD deficiency, was reported by 43 mothers (4%). Families commonly avoided exposure of their newborns to direct sunlight (88%) and kept their newborns in dark rooms during the first 7 days (77%). The old Chinese literature also had very detailed and accurate description of the clinical features of kernicterus. Herbal medicine has been used to treat NNJ for a long time, and is still practiced in some parts of China up to the recent decades. The infants were, however, at the same time treated with a variety of other herbs or herbal combinations, as well as western medicine including steroids, plasma, phototherapy, phenobarbitone, and exchange transfusion.

Keywords: Neonatal Jaundice, Pregnancy, Risk Factors, Traditional Approach, Bilirubin, Kernicterus

Introduction

Neonatal jaundice is a common event that occurs especially in the first week of birth [1] [2] [3] and is one of the most common causes of hospitalisation of the term and preterm neonates in neonatal wards [1]. Based on the present evidence, 80% of premature infants have clinical symptoms, including yellowish skin and sclera, caused by serum bilirubin levels [4] [5]. Hyperbilirubinemia is a common disease that occurs especially in the first week of birth [1] [2] [3] and is one of the most common causes of hospitalisation of the term and preterm infants in neonatal hospitals [1]. It usually occurs on the second day of birth and is not usually harmful, and a self-limiting condition, where disease usually improves without treatment after reaching the normal amount of bilirubin [6] [7], but very high levels of bilirubin may lead to kernicterus as permanent brain damage. Nevertheless, diagnosis of newborn jaundice and its management will play an important role in the health of newborns [8]. If jaundice lasts more than 14 days, it is called to be prolonged neonatal jaundice [6].

An imbalance between bilirubin production and conjugation is the main mechanism of jaundice, which leads to an increase in bilirubin levels. This imbalance often occurs due to the immature liver and the rapid breakdown of red blood cells, which may be involved with several factors [9] [10] [11] [12]. The indirect bilirubin value in the physiologic jaundice of the term neonates does not exceed 12 mg/dL on the third day, and, this maximum increase reaches 15 mg/dL in preterm infants on the fifth day [13].

In physiologic jaundice, the maximum indirect bilirubin of infants who fed breast milk may be higher than those fed with *skimmed milk* (15-17 mg/dL versus 12 mg/dL); this higher level is probably due to the lower consumption of fluid by infants who are breastfeeding [14].

Types of Hyperbilirubinemia

Several types of Bilirubinemia have been reported in neonates including physiological jaundice, pathological jaundice, jaundice due to breastfeeding or breast milk and hemolytic jaundice including three subtypes due to Rh factor incompatibility, ABO blood group incompatibility and Jaundice associated with Glucose-6-phosphate dehydro-genase (G6PD) deficiency [15].

Physiological Jaundice

It is the most abundant type of newborn hyperbi-lirubinemia, having no serious consequences [16]. Neurodevelopmental abnormalities including as athetosis, loss of hearing, and in rare cases intel-lectual deficits, may be related to high toxic level of bilirubin [17]. Jaundice attributable to physio-logical immaturity which usually appears between 24-72 h of age and between 4th and -5th days can be considered as its peak in term neonates and in preterm at 7th day, it disappears by 10-14 days of life [18]. Unconjugated bilirubin is the predomi-nant form and usually its serum level is less than 15 mg/dl [19]. Based on the recent recommenda-tions of the AAP, bilirubin levels up to 17-18 mg/dl may be accepted as normal in term of healthy newborns [20].

Pathological Jaundice

Bilirubin levels with a deviation from the normal range and requiring intervention would be de-scribed as pathological jaundice [16].

Breast Feeding and Breast Milk Jaundice

Exclusively infants with breastfeeding have a dif-ferent physiological pattern for jaundice com-pared with artificially feed babies [15]. Jaundice in breast fed babies usually appears between 24-72 h of age, peaks by 5-15 days of life and disappears by the third week of life. Higher bilirubin levels have been reported in these infants [21].

Hemolytic Jaundice

The most common causes of hemolytic jaundice include (a) Rh hemolytic disease, (b) ABO incom-patibility and (c) Glucose-6-phosphate dehydro-genase (G-6-PD) deficiency and minor blood group incompatibility.

(A) Rh Factor Hemolytic Disease

Rhesus hemolytic disease of the newborns (RHDN) results from maternal red-cell alloimmunization [22].

(b) ABO Incompatibility

The incidence of the incompatibility of the ABO blood groups of the mother and fetus, when the mother has the blood group O and the newborn has the A or B blood group, is 15-20% of all pregnancies [23].

(c) Jaundice Associated With G6PD Defi-ciency

Deficiency, hereditary spherocytosis, and minor group incompatibilities should be managed simi-lar to ABO incompatibility. G6PD, most com-mon enzymopathy, is the deficiency of an en-zyme in RBCs [24].

Clinical Examination of Jaundice

Originally described by Kramer [25], dermal staining of bilirubin may be used as a clinical guide to the level of jaundice. Dermal staining in newborns progresses in a cephalocaudal direction [26].

Measurement of Bilirubin Levels

Bilirubin level can be checked through biochemi-cal method, Bilimeter or trans cutaneous bilirubinometer [26].

Biochemical

The gold standard method for bilirubin estima-tion is the total and conjugated bilirubin assess-ment based on the van den Bergh reaction [27].

Bilimeter

Spectrophotometry is the base of Bilimeter and it assesses total bilirubin in the serum. Because of the predominant un-conjugated form of bilirubin, this method has been found a useful method in neonates.

Transcutaneous Bilirubinometer

This method is noninvasive and is based on the principle of multi wavelength spectral reflectance from the bilirubin staining in the skin [27].

Instructions and Precautionary Measure for Parents during Physiological Jaundice

The benign nature of jaundice should be explained and demonstrated to the parents. The mother should be encouraged to breast-feed her baby frequently and exclusively, at least eight to twelve times per day for initial several days, with no top feeds or glucose water whatsoever [25]. Mother should be told to bring the baby to the hospital if the color on the legs looks as yellow as the face. Any newborn discharged before 48 h of life should be evaluated again in the next 48 h for

breastfeeding sufficiency and development of jaundice [25].

Care Practices, Risk Factors, and Beliefs

The majority of women initially breast- and formula fed their infants while waiting for their breast milk to come in. After the first week, however, the vast majority exclusively breast-fed. Exclusive formula feeding was rare. Mothball use, a possible trigger for hemolysis in newborns with G6PD deficiency, was reported by 43 mothers (4%). Families commonly avoided exposure of their newborns to direct sunlight (88%) and kept their newborns in dark rooms during the first 7 days (77%). When asked about the effects of sunlight on newborns, 33% thought sunlight was harmful of whom 171 thought it damaged the skin and/or eyes, 142 believed newborns were "too young/weak" and "would get sick" if exposed, and 2 thought it caused congestion. On the assessment of maternal knowledge of jaundice and found that less than half had ever heard of newborn jaundice, and only 27% thought that jaundice could potentially be harmful. Only 11% received teaching on jaundice after birth.

On the inquiry about the home use of traditional, herbal, or over-the-counter treatments, as these might delay care-seeking behavior and newborn follow-up care. One-hundred sixty-four mothers reported using traditional, herbal, or over-the-counter treatments for newborn problems during the first week. Thirty used herbal remedies to treat jaundice. Although cost was the most commonly reported potential barrier to care (17%), the majority reported none. Routine well-baby follow-up care before 14 days was rare (2.5%); 6% of mothers sought newborn care for medical concerns during the first 2 weeks after birth.

Table 1: Average Incidence of Risk Factors for Neonatal Jaundice

Mean of Incidence	Incidence Range	Incidence of Risk Factor
Hypertension (11.85%)	Hypertension (4.7–19%)	Hypertension (4.7%), hypertension (19%)
Preeclampsia (14.3%)	Preeclampsia (14.3%)	Preeclampsia (14.3%)
Vaginal bleeding (3.3%)	Vaginal bleeding (3.3%)	Vaginal bleeding (3.3%)
Diabetes (6.14%)	Diabetes (2.78–9.5%)	Diabetes (2.78%), diabetes (9.5%)
Premature rupture of membranes (2.7%)	Premature rupture of membranes (2.7%)	Premature rupture of membranes (2.7%)
Natural vaginal delivery (45.85%)	Natural vaginal delivery (16.7–75%)	Natural vaginal delivery (58.1%), NVD (75%), NVD (58.2%), NVD (73.5%), NVD (16.7%), NVD (48.48%), NVD (58%)
Maternal infections (3.45 %)	Maternal infections (3.45 %)	Maternal infections (3.45 %)
Preterm delivery (33.3%)	Preterm delivery (32–35%)	Preterm delivery (32.9%), gestational age under 32 weeks (35%), gestational age 35 weeks and higher (32%)
Use of herbal medicines based on maternal cultural beliefs (69.4%)	Use of herbal medicines based on maternal cultural beliefs (69.4%)	Use of herbal medicines based on maternal cultural beliefs (69.4%)
Reduction in breastfeeding rate (21.21%)	Reduction in breastfeeding rate (21.21%)	Breastfeeding (91%)

Pregnancy Problems

One of the maternal problems that affects neonatal jaundice incidence, is premature delivery and also premature birth. In a study, 30% of cases of neonatal jaundice were due to prematurity. Uridine diphosphoglucuronide acid-glucuronyl transferase (UDPGT) enzyme maturity is related to gestational age: the activity of this enzyme is one third among infants with 32 weeks of gestational age compared to term neonates, and as a result, the possibility of jaundice and its complications is increased in premature infants. On the other hand, delay in milk production and weakness of infant sucking lead to decreased caloric intake, dehydration and increase in enterohepatic circulation of bilirubin, thus resulting in increased concentration of bilirubin [28, 29].

PROM was also a maternal risk factor. In previous studies, the history of PROM in pregnancy was observed in 1.7%–4.8% of infants with jaundice. In a study, prolonged rupture of membrane was one of the maternal predisposing factors relevant to neonatal jaundice. In 40% of premature cases, there is a history of PROM. Thus, prematurity may be the main cause of jaundice in newborns with PROM [30].

Another risk factor for neonatal jaundice is ABO incompatibility, the result of mother's O blood group and nenonate's A or B blood group. ABO incompatibility, G6PD enzyme deficiency, prematurity, cephalohematoma, and RH incompatibility were the most prevalent risk factors for early neonatal jaundice. Also, there was a significant correlation between ABO incompatibility and jaundice prevalence.

Herbal Treatment of Neonatal Jaundice (NNJ)

Jaundice was described in Chinese literature as early as 3000 years ago. In the first Chinese medical book, Nei Ching, which was written in 1000 BC, jaundice

was described as ''yellow skin, yellow sclera, yellow urine.'' NNJ was first described in the book ''On the Origins and Symptoms of Diseases'' written in 610 AD, in which NNJ was alleged to be caused by the ''heat'' produced by the mother's viscera. ''Heat'' is a common Chinese medical term used to describe all kinds of physiological and pathological dysfunctions of the body. NNJ in the Chinese medical concept is a condition that originates from intrauterine life. NNJ was referred to as ''tai huang,'' meaning fetal jaundice. Another term ''tai dan'' referred to more severe jaundice, which might be the equivalent of pathological jaundice in modern terms. NNJ had been attributed to both ''internal'' and ''external'' causes. Internal causes that have been implicated included ''heat and moisture'' acquired from the womb or breast milk. External causes that have been described included toxins and demons, which most likely referred to infective agents. The Chinese medical practitioners also recognized ''weakness'' and ''lack of protection'' of the newborns. Biliary obstruction, referred to as ''stasis of blood flow,'' as well as inherited conditions had also been mentioned as causes of NNJ. The old Chinese literature also had very detailed and accurate description of the clinical features of kernicterus. Herbal medicine has been used to treat NNJ for a long time, and is still practiced in some parts of China up to the recent decades. The infants were, however, at the same time treated with a variety of other herbs or herbal combinations, as well as western medicine including steroids, plasma, phototherapy, phenobarbitone, and exchange transfusion. In the Chinese medical literature, the pharmacological properties of these herbs had been described. Many of these herbs have a bacteriostatic effect on a number of bacteria. Some have been shown to have an immunosuppressive effect on the anti - A, anti - B, and anti –D antibodies. A choleretic action of increasing bile excretion by rendering bile juice more dilute has been observed in some. Gancao contains ingredients with adrenocorticosteroid action. A number of case series have been published showing that herbal treatment using ''Yin chin'' and other herbs resulted in more speedy subsidence of jaundice than those who were treated with western medicines. However, little is known about the nature of these western medicines or the methodology used in these studies. In the English literature, there is a report on a study investigating the effect of Yin chin, Gardenia, Da huang, and Huang qin on bilirubin metabolism in rats. The finding showed that treatment with these herbs resulted in induction of UDP glucuronide transferase and C- glutathione transferase. The effects, however, were only small compared to the enzyme induction property of phenobarbitone. It can be concluded that although herbal treatment of NNJ has been practiced for a long time in China, its effectiveness remains doubtful and no convincing evidence, either pharmacological or epidemiological, has demonstrated its usefulness. The evaluation of the role of herbal treatment in NNJ requires properly conducted randomized clinical trials.

Conclusion

Evaluation of risk factors for neonatal hyperbilirubinemia is important because high risk factors play an important role in neonatal jaundice in a Hospital. Large-scale studies are also needed for further and also by the control group. Since the promotion of neonatal health as a vulnerable group in the health care services has a special place, so the evaluation of neonatal jaundice in all levels of health services should be considered as a fundamental policy. Medical scientists should search for new treatments and preventive measures having no side effects and capable of recovering babies more speedily. Partners should screen their ABO blood groups as well as Rh fac-tor before marriage. Consanguineous marriages should be avoided. In conclusion, reviewing studies addressing maternal risk factors for neonatal jaundice has shown that maternal risk factors play an important role in the incidence of neonatal jaundice. These risk factors included maternal age, hypertension, diabetes, cesarean section, birth order, PROM, preterm delivery, LBW, frequency of breastfeeding and neonatal weight loss. Therefore, regular and effective care seems to be necessary during pregnancy including training about the harmful effects of some herbal medicines, proper nutrition for the mother and normal delivery, and moreover, following-up the baby in case of complications such as PROM, GDM, high blood pressure and preeclampsia during pregnancy in order to prevent premature birth and neonatal sepsis, which are important causes of hyperbilirubinemia.

Abstract

The aim of the present study was to investigate cord clamping practice and treatment approaches for term vaginal births in Indian hospital, where the majority of births have an Obstetrician as the lead. A stopwatch was used to time the cord clamping interval at 55 term vaginal births in a tertiary hospital. The stopwatch was pressed once at the time of the birth and once when the first clamp was applied to the umbilical cord. Mode of birth, maternal position for birth and whether midwives and or doctors and neonatal health practitioners were involved in the birth was documented alongside the cord clamping timing. Cord clamping timing ranged from a minimum of 14 seconds to a maximum of 34 minutes. The median umbilical cord clamping time for all births in the study was 3.5 minutes. The median cord clamping time was likely to be longer when the woman had a spontaneous vaginal birth rather than an instrumental birth; when she birthed in a side-lying or upright position rather than a seated position; when a midwife facilitated the birth rather than a doctor and when there was no neonatal team present at the birth. The median cord clamping time of 3.5 minutes is aligned with current local, national and international guidelines. Midwives are likely to facilitate longer cord clamping times as they are more likely than doctors to attend spontaneous uncomplicated births which do not warrant immediate separation of mother and baby for preventative or resuscitative measures.

Keywords: Resuscitative measures, Cord clamping, Spontaneous vaginal birth, Behavior and Umbilical Cord Clamping, Neonatal Jaundice

Introduction:

Since its introduction as one of the first ever interventions in childbirth, umbilical cord clamping has been the topic of ongoing historical debate, physiological speculation and a multitude of experimental studies. As with many childbirth interventions, cord clamping does not stand alone but is instinctively linked with other interventions such as active management of the third stage of labour and newborn resuscitation. With the rapidly growing evidence around the harms of immediate cord clamping, in particular a reduction in blood volume leading to low iron stores for infants at three to six months of age (McDonald *et al.*, 2013).

When a cord is left attached to the placenta after birth, a significant proportion of the blood will flow from the placenta to the newborn contributing to between one-third and one-quarter of total potential blood volume at birth (Farrar *et al.*, 2011; Yao *et al.*, 1969; Begley *et al.*, 2019).

Methods

After performing an extensive literature review it became evident that, despite a dramatic change in guidelines for health practitioners around when to clamp the cord, little evidence existed on whether this guidelines was being implemented into practice in the current maternity system. In response to this gap in knowledge, the Timing of Cord Clamping (TOCC) study was devised to measure actual timings and some of the influences on current practice.

The TOCC study is a descriptive observational study of cord clamping practice at term vaginal births in a tertiary hospital.

Quantitative research methodology was chosen because the aim was to quantify practice, i.e. to accurately measure the time interval between birth and cord clamping. A question that lends itself to numerical measurement is best resolved from a positivist paradigm, in an objective and observable way, using quantitative methodology (Dyson & Norrie, 2013). A relatively large data set can be analysed when a quantitative methodology is used. When these data are examined using statistical techniques, a summary of trends and underlying patterns in clinical practice can be produced. Although the TOCC study answered important questions around the actual timing of cord clamping it did not provide us with an in-depth insight on how the individuals involved perceived or interpreted the situation. Further research from a qualitative perspective

would be a useful follow up to the TOCC study to allow us to describe personal experiences of the women and the health practitioners at the time of birth.

The research involved an observational study of cord clamping practice. In an observational study, information is collected first hand by a researcher based on how people are seen to behave or interact in certain situations (Rees, 2011). The investigator has no control over study variables and merely observes outcomes. This has less risk involved than an interventional study, in which changing an aspect of clinical practice may have a detrimental impact on healthcare (National Ethics Advisory Committee, 2012). Overt participant observation has the advantage over questionnaires and interviews as it is more likely to record accurate data, by avoiding the significant discrepancies that may exist between self-reported estimations and objective measurement (Hutton *et al.*, 2013). People are not always able to accurately describe or articulate their own actions. Unlike surveys, observation does not rely on memory, and therefore data is likely to be more accurate (Rees, 2011).

The data obtained from this observational study was examined using descriptive statistics to identify any relationships between umbilical cord clamping timing and the circumstances of each birth. The term "descriptive", when used in relation to statistics, indicates that data will be described and summarised rather than using inferential statistics which are more able to be generalised to the wider population (Dyson & Norrie, 2013).

One of the aims of the TOCC study was to compare Indian birth data collected from July 2019 to June 2020 to data collected ten years earlier in an Indian study where births were observed (Hutton *et al.*, 2013). In both studies, the context was a large tertiary hospital where births are conducted by both doctors and midwives. Of particular interest is the change in cord clamping practice over the ten years between studies. In addition, a comparison is made between two different maternity systems: a system where the majority of women (94.2%) choose a midwife as their lead maternity career and a other system where the majority women (93%) have an obstetrician or family physician as their lead maternity carer (Guliani, 2015).

Study Protocol

This study was informed by an observational study of cord clamping practice in a tertiary hospital (Hutton *et al.*, 2013). The TOCC study observed term vaginal births, both spontaneous and instrumental, in order to provide a data set comparable to the Hutton *et al.* study.

Health practitioners working in a birthing suite in Indian tertiary hospital were asked to use a stopwatch to time the interval between the birth of a baby and the time when the first clamp was applied to the cord. No extra research person was at the birth in the TOCC study: the stopwatch duty was allocated to a member of staff who would otherwise have been present in the birthing room. This differed from the Hutton *et al.* study, which used researchers as additional attendees at the birth. Where the research role is allocated to a midwife who attends to assist the LMC at a birth, they are in an ideal role to at act as overt participant observer as they are familiar with the environment and thus have the insider's perspective. Another crucial advantage of using the hospital midwives as participant observers is that it negates the need for a separate researcher to be in the room (in addition to the existing birth attendants) which may have a negative influence on the birth 'territory' (Hastie & Fahy, 2009).

It is conceivable that this observational study would add stress to women at time of their birth, an outcome that the investigator was keen to avoid. However, as the study was observing the health practitioners and not directly the woman, it was anticipated that this stress would be minimized. Health practitioners participants in the TOCC study were advised that, if there was an emergency procedure at the time of birth, TOCC study requirements would cease if they were likely to have an impact on normal management of the birth. The aim was to mitigate any risks by informing the assisting midwife that the stopwatch was never to take precedence over any usual care. It is recognized that many other factors could have been included in this study that may have an influence on cord clamping timing. As described in the Locality section below, the initial data collection table was more extensive but the table was restricted to make it more manageable for the health practitioners recording data for the study. Rees (2011) suggests that the number of activities recorded as part of observational studies needs to be limited so that observers are not overwhelmed when events unfold quickly, as they do during a birth.

All participants, both pregnant women and maternity healthcare professionals were provided with information on the study. Information leaflets and consent forms were designed as part of the ethics application. Copies of this supporting documentation is included in Appendices two and three. In order to compare findings to a previous observational study of cord clamping (Hutton *et al.*, 2013). Sample size of 100 term vaginal births at the chosen tertiary hospital.

Exclusion & Inclusion Criteria

Women who birthed breech babies, multiple babies, who birthed prior to 37 weeks and/or who birthed outside of the tertiary unit were excluded from this study as these situations affect the decision-making around cord clamping. Women who birthed vaginally assisted by ventouse (suction) and/or forceps were included in the study but not births that progressed to caesarean section. Variations in cord clamping timing do exist at caesarean section and indeed, at the time of the study the local guideline recommended an interval of 2 minutes for operative birth (CDHB, 2018). However, caesarean births were excluded from the TOCC study to further attempt to provide an accurate comparison to a previous cord clamping observational study (Hutton *et al.*, 2013). It is

likely that results may have been quite different if the sample had included caesarean and preterm births or had the study been conducted in a primary midwifery- led setting.

After obtaining consent, and prior to delivery, the forth coming newborn was randomly assigned to either delayed cord clamping (DCC) or immediate cord clamping (ICC) group. In the DCC group the umbilical cord was clamped after 30 seconds or when it stops pulsating. The exact time was recorded by use of a stopwatch, with complete expulsion of the infant as starting point. In the ICC group clamping was done within 10 seconds after delivery. A sample of cord blood was collected from the placental side after clamping and ligating the fetal side for Hemoglobin and Hematocrit estimations. Before discharging home (usually at 36-48hrs of life) the babies was assessed for clinical signs of polycythemia, hyperviscocity or hyperbilirubinemia.

Data Collection and Analysis

The initial aim was for hospital midwives to be trained as participant observers, and to collect specific data at births attended as a 'second midwife'. However, due to the acknowledgement that very little training is needed to use a stopwatch, during data collection the most appropriate member of staff present at the birth did the timings. This was often the hospital midwife, but may also have been the LMC or a delegated student (midwifery or medical). The stopwatch was pressed once at the time that the entire baby was born and then again when the first clamp was applied to the cord.

Results

The TOCC study ran from July 2019 to June 2020. Recruitment for the TOCC was slower than anticipated despite efforts to promote the study to LMCs and directly to pregnant women. At the beginning, after five months of recruitment, 30 births had been recorded in the study notebook and therefore recruitment was extended for a further 4 months in order to allow more time for the full quota of 100 births. The first birth to have data recorded was on the August 2019 and the last birth was recorded on April 2020. Data on 56 term vaginal births were collected. There were no twin births in the TOCC study data.

Of the 36 health practitioners who consented to have information collected from births that they facilitated, 31 were midwives and eight were doctors. Most of the health practitioners had one birth timed as part of the TOCC study. One midwife had 22 births timed, another midwife had nine births timed, two midwives each had two births timed. The information in the TOCC notebooks was collected by LMC midwives or hospital midwives, including for births where a doctor was facilitating.

Consent forms were collected for the 56 women who had their births recorded as part of the TOCC study. It is not known how many women consented to the study and then were not included in data collection as these consent forms were not collected.

Exclusion

One birth was excluded from the data analysis. The words "36 weeker" were documented in the comments box. This was outside the TOCC study criteria of 37 or more weeks gestation. With this birth excluded, the final number of births included for analysis was 55. The data were presented in table 1.

Table 1: Exclusions Criteria (Cord clamping times of all study participants)

Particular	n
Births where consent obtained and data collected	56
Exclusions (36 week gestation)	1
Births for analysis	55

The median umbilical cord clamping time for all births in the TOCC study was 3.5 minutes. For the purpose of analysis, times have been converted from stopwatch display of minutes:seconds:centiseconds to minutes to two decimal places.
The range of umbilical cord clamping times in the TOCC data set was from 0.23 minutes to 34 minutes. The inter quartile range (IQR) describes the middle 50% of these times. The 25^{th} centile for the TOCC data is 2.18 minutes and the 75^{th} centile is 5.68 minutes. Therefore, the IQR is 2.18 -5.68. The IQR can also be represented as a calculated range, i.e. 5.68 - 2.18 = 3.5 minutes. The data were presented in table 2.

Table 2: Cord clamping time for all study participants

Particular	Cord clamping time (minutes)
Range	0.23 - 34.00
Median (IQR*)	3.50 (2.18 - 5.68)

Frequency distribution of cord clamping times

Four babies had their cords clamped less than one minute after their birth and seven babies had their cords clamped over ten minutes after their birth. The majority of babies (64%) had their cords clamped between one and five minutes. The data were presented in table 3.

Table 3: Frequency distribution of cord clamping times

Cord clamping time (minutes)	n (%)
Less than 1	4 (7%)
1-2.99	16 (29%)
3-4.99	19 (35%)
5-9.99	9 (16%)
More than 10	7 (13%)

Where the interval between baby's birth and placental birth was longer than 10 minutes, birth health practitioners were asked to record >10 in the study notebook. The reason for not requesting a precise figure was because, in planning for the study, it was anticipated that data collection would usually be done by a hospital-employed midwife and that she or he was unlikely to be able to stay beyond ten minutes to stop the time on the stopwatch due to other birthing suite demands. In reality, it was often the Lead Maternity Carer midwife who used the stopwatch and who was then present beyond the birth of the placenta. When results were analyzed, seven births had a cord clamping time of more than ten minutes. Of these seven births, four midwives chose to document the precise time and three midwives chose to document the time as ">10". As the majority of this data was known, I chose to add actual times to the data set. In the four cases where precise times were recorded, the cord clamping time ranged from 11.85 minutes to 34 minutes.

Where the cord was clamped before the full birth of the baby's body, e.g. when the cord was wrapped tightly around the baby's neck, healthcare health practitioners were asked to document this as 0 minutes. No births in the TOCC study were recorded as 0 minutes.

Mode of birth and cord clamping times Of the 55 births in the TOCC study, 45 (81.8%) were spontaneous not in water, one (1.8%) birth was spontaneous in water and nine (16.4%) births were instrumental. Mode of birth is represented in Figure 2. Due to the low number of water births, the results for spontaneous births both in and out of water have been combined.

The median cord clamping time for a spontaneous birth (3.71 minutes) was longer than for an instrumental birth (2.08 minutes). The IQR for a spontaneous birth (2.67 - 6.23) was wider than for an instrumental birth (0.55 - 2.30), indicating that there was more variation in the cord clamping practice at spontaneous births. The maximum time that a cord was left intact at an instrumental birth was 4.15 minutes, whereas for a spontaneous birth the maximum time was 34 minutes. This data is included in table 4.

Table 4: Cord clamping times according to mode of birth

Mode of birth	n (%)	Range	Median (IQR)
Spontaneous (in or out of water)	46 (83.6%)	0.33 - 34.00	3.71
Instrumental (ventouse or forceps)	9 (16.4%)	0.23 - 4.15	2.08

Spontaneous births were most likely (29/46: 63%) to be followed by a cord clamping time of between 1 and 5 minutes. Instrumental births were most likely (7/9 :78%) to be followed by a cord clamping time of between 0 and 3 minutes. None of the births in the instrumental group had a cord clamping time of over 5 minutes whereas 35% of the births in the spontaneous group had a cord clamping time of over 5 minutes.

Table 5: Frequency distribution of cord clamping times according to mode of birth

Cord clamping time category (minutes)	Spontaneous n	Instrumental n
Less than 1	1	3
1-2.99	12	4
3-4.99	17	2
5-9.99	9	0
More than 10	7	0
Total	46	9

There was significant difference in mean hematocrit at 24 hr in Immediate group and Delayed group. There was significant difference in mean bilirubin at 24 hr in Immediate group and Delayed group. There was some reduction in hemoglobin (cord blood) (g/ dl) and hematocrit (cord blood)(%) from birth to 24 hr and increase in Bilirubin (cord blood) (mg/dl) from birth to 24 hr in both the groups. Clinical jaundice was found in baby in both the group at birth. The data were presented in table 5 & 6.

Table 6: Comparison of investigation at birth and at 24 hr in ICC Group and DCC Group

	ICC					DCC				
Investigations	at birth		at 24 hr			at birth		at 24 hr		
	Mean	S.D	Mean	S.D	mean	Mean	S.D	Mean	S.D	mean
hemoglobin (cord blood)	17.28	0.86	17.13	0.77	0.17	18.68	0.74	18.44	0.78	0.25

TREATMENT OF NEONATAL JAUNDICE AFTER PARTURITION

1. All women should be encouraged to breastfeed 8 to 12 times a day
2. Supplementation is recommended only for dehydrated newborns and where weight loss from birth is >10%. Expressed breast milk is the preferred supplementation.
3. Routine supplementation with intravenous fluids, honey or dextrose water for newborns with jaundice is not recommended
4. No interruption of breastfeeding should be done for any jaundice.

- Phototherapy can be delivered by light - emitting diode (LED) or fibreoptic or fluorescent lamps or tubes or bulbs.
- Do not use sunlight as treatment for hyperbilirubinaemia. Exposing the baby to sunlight does not help in treatment of jaundice and is associated with risk of sunburn and therefore should be avoided.

5. Exchange transfusion should be done by central or peripheral route aiming replacement of double the baby's blood volume and by skilled personnel in a well-equipped centre.

6. Immediate EBT is recommended if infant shows signs of ABE or if TSB is ≥25 mg/dL above the recommended age and risk specific cut off TSB
7. For Rhesus is immunization, the best choice would be O (Rh) negative packed cells suspended in AB plasma. (Rh) negative whole blood or cross-matched baby's blood group (Rh negative) may also be used.
8. For ABO is immunization, O group (Rh compatible) packed cells suspended in AB plasma or O group whole blood (Rh compatible with baby) should be used.
9. In other situations baby's blood group should be used. All blood must be cross matched against maternal plasma.

Discussion

Cord clamping was one of the earliest interventions to be introduced to birthing practice. Immediate clamping became widely adopted in the 1960's as part of active management of the third stage of labour, introduced to reduce adverse outcomes from postpartum haemorrhage. However, the review of the literature in chapter two demonstrated multiple benefits for infants who have deferred cord clamping without an increase in maternal haemorrhage rates.

In the TOCC study, able to accurately record the interval between birth and cord clamping at 55 term vaginal births in a tertiary hospital. The median was 3.5 minutes and the IQR was 2.18 - 5.68 minutes, while the shortest cord clamping time was 0.23 minutes and the longest was 34 minutes. These results are indicative of a move towards longer cord clamping times in practice. Newborns in the TOCC study were more likely to receive a prolonged period of cord clamping if their mother birthed in an upright or side-lying position rather than seated position, when the birth was spontaneous rather than assisted by forceps or ventouse, where the birth was facilitated by a midwife rather than a doctor and where there was no neonatal team in attendance.

The median cord clamping time in this study was 3.5 minutes which demonstrates a move away from immediate cord clamping. However, the optimal time for cord clamping is unknown. Blood continues to flow through the cord after the birth accounting for approximately one-quarter to one-third of potential total blood volume in term babies (Farrar *et al.*, 2011; Yao *et al.*, 1968). Most studies define immediate cord clamping as within the first 15 seconds of birth, with delayed/deferred cord clamping ranging from one to five minutes post birth (if a time value was used) or sometimes defined as the cord being clamped after pulsations ceased and/or after placental birth (Hutton & Hassan, 2007; McDonald *et al.*, 2013).

It is still not clear whether the optimal time for cord clamping should be an actual time point, such as one minute or five minutes, or whether it should be related to other factors such as neonatal breathing efforts. Physiological studies on humans and animals demonstrate that placental transfusion is dependent on a number of factors and therefore a "time value" for optimal cord clamping is individual for each newborn. There is a move to use terminology such as "Wait for White", to recommend waiting until the cord is flaccid and empty of blood (Burleigh, 2016), "Aerate-Breathe-Clamp" or "Physiological-Based Cord Clamping" to recommend individualised practice according to the newborn response to extra-uterine transition (Knol *et al.*, 2019).

In the TOCC study, the position associated with the longest interval between birth and cord clamping (median 6.37; IQR 4.15 - 9.48) was side-lying, adopted by women at 7/55 (13%) births. In the author's experience, births in the side-lying positions are often followed by an initial period of the newborn lying alongside the woman, on a flat surface and in skin-to-skin contact. This flat surface allows the birth to position the baby with an effective open airway and thus to encourage newborn spontaneous breathing with an intact cord without having to disturb maternal or infant position. In contrast, with seated/recumbent positions the newborn will lie on the mother's abdomen which is less likely to be an effective flat surface to assist airway opening and is more likely to be interrupted if the woman has to move.

Conclusion

The main finding of this study was a median cord clamping time of 3.5 minutes for the 55 term vaginal births observed at a tertiary hospital where the majority of births have an Obstetrician as the leads.

The TOCC study aimed to accurately record birth to cord-clamping interval at 100 term vaginal births and to investigate factors which may influence practice such as mode of birth, maternal position for birth and health practitioners involvement. In the final analysis, despite a three-month extension in the recruitment period, the total number of births accurately recorded was 55. While a larger study may provide more generalisable results, there would likely still be considerable challenges to recruitment unless significant resourcing was available. The consistency of findings in this small study does provide confidence that there has been a shift to longer cord clamping times.

Clamping and cutting of the umbilical cord at birth is the oldest and most prevalent intervention in humans. Various studies have advocated the practice of DCC which was found to be true in our study as well. Moreover there were no significant associated adverse effects. It is a safe, simple and low cost delivery procedure that should be incorporated in integrated programs.

ABSTRACT

Objective: The present study was carried out to find out the prevalence of various thyroid disorders among pregnant women in their first trimester in the southern area of Rajasthan.
Material & Methods: The study was conducted during the period of 1year from July 2017 to July 2018. 200 pregnant women attending antenatal clinic for their routine antenatal visit in first trimester were included in the study. Routine blood and urine investigations along with serum TSH, FT3 and FT4 were done in all the study participants.
Results: Age of the patient's ranged from 19 to 38 with the mean age of 25.66±3.90 years. Mean gestational age of study population was 8.12±1.63 weeks. The mean TSH, FT3 and FT4 values were 1.499, 2.386 and 1.410 respectively. Thyroid disorders were found in 14%patients out of 200 study participants. 86% patients were euthyroid among the study participants. 7% patients were found to be having subclinical hypothyroidism. 4% were having overt hypothyroidism and 3% were having subclinical hyperthyroidism.
Conclusion: The study revealed high prevalence of thyroid disorders (14%) among pregnant women in their first trimester specially hypothyroidism (11%). Routine antenatal thyroid screening should be performed in all pregnant women.

Keywords: Hypothyroidism, antenatal, hyperthyroidism, eclampsia

INTRODUCTION

Normal thyroid hormone levels are necessary in maintaining pregnancy and in development of fetus. Thyroid dysfunctions are more common in female than in male. Maternal thyroid functions changes during pregnancy and leads to thyroid disorders in absence of adaptation to these changes. Thyroid disorders during pregnancy can result in substantial adverse fetomaternal outcomes. Furthermore, thyroid dysfunction can be readily diagnosed with simple and reliable blood tests and easily corrected with economical and easily available treatments. [1]

Worldwide, thyroid disorders are common in women of child-bearing age. [2] During pregnancy, demands on the hypothalamic-pituitary-thyroid axis increases which commonly leads to borderline thyroid abnormalities. Both hyper and hypo-thyroidism types of thyroid disorders can occur during pregnancy and correction of these disorders dramatically reduces the risk of adverse fetomaternal outcomes like foetal loss, preterm birth, pre-eclampsia and eclampsia and maternal morbidity. [3, 4]

According to the western literature, the prevalence of hypothyroidism in pregnancy is around 2.5%. The prevalence of gestational diabetes is around 0.1–0.4% and that of thyroid autoimmunity (TAI) is around 5-10%. [5]

There are very few data from India about the prevalence of thyroid dysfunction in pregnancy especially in the southern Rajasthan. With this background, the present study aims to find the prevalence of thyroid disorders including hyperthyroidism, hypothyroidism and Subclinical Hypo and hyper- thyroidism during pregnancy in southern part of Rajasthan.

MATERIALS AND METHODS

The present study was a prospective study carried out in the department of Gynaecology and Obstetrics, Ananta institute of medical sciences, Rajsamand during the period of 1 year from July 2017 to July 2018.

200 patients attending OPD in their first trimester for routine antenatal check up were randomly selected and included in the study.

Inclusion criteria:

1. ≤ 12 week gestation
2. Singleton pregnancy
3. Primi/ multigravidae

Exclusion criteria:

1. Patients who were not willing to give consent.

Procedure:

Detailed history of all the patients was taken regarding symptoms of thyroid disorders, past medical and obstetric history, family history and personal history. Complete general and systemic examination was done in all the patients. Per abdominal and per vaginal examination were also done and findings were recorded.

Routine blood and urine investigations along with serum TSH, FT3 and FT4 were done in all the study participants. Pregnancy ≤12 week was confirmed by clinical examination, pregnancy test and ultrasonography. The reference ranges of the test values used in this study were as per the Guidelines of American Thyroid Association (ATA) for the diagnosis and management of thyroid disease during pregnancy and postpartum. As per regulation 14.2 of ATA Guidelines, if trimester specific ranges for TSH are not available in the laboratory, the following normal reference ranges are recommended: 1st trimester - 0.1 to 2.5 m IU/L, 2nd trimester - 0.2 to 3.0 m IU/L and 3rd trimester - 0.3 to 3.0 m IU/L. Normal free T4 level is 0.7 to1.8 ng/ml and free T3 level is 1.7 to 4.2 pg/ml.

Ethical consideration: Permission was taken from institutional ethical committee and written consent was taken from all the study participants.

RESULTS

200 pregnant women in their first trimester were included in present study. Age of the patients ranged from 19 to 38 with the mean age of 25.66±3.90 years. Mean gestational age of study population was 8.12±1.63 weeks.

The mean TSH, FT3 and FT4 values were 1.499, 2.386 and 1.410 respectively. (Table 1)

Table.1 Baseline parameters of the study participants

S.No.	Parameters	Value (Mean ±SD)
1	Age	25.66±3.90 years
2	Gestational Age	8.12±1.63 weeks
3	TSH	1.499±0.324 IU/L
4	FT3	2.386±0.537 ng/ml
5	FT4	1.410±0.461 pg/ml

Thyroid disorders were found in 28 cases (14%) out of 200 study participants. Table 2 illustrates variety of thyroid disorders in the study population. 86% patients were euthyroid among the study participants. 7% patients were found to be having subclinical hypothyroidism. 4% were having overt hypothyroidism and 3% were having subclinical hyperthyroidism.

Table 2. Percentage of thyroid disorders in study participants

S.No.	Type	Number	Percentage
1	Euthyroid	172	86
2	Overt Hypothyroidism	8	4
3	Subclinical hyperthyroidism	6	3
4	Subclinical hypothyroidism	14	7
5	Overt Hyperthyroidism	0	0
6	Total	200	100

DISCUSSION

The present prospective study was conducted in a tertiary healthcare centre of southern Rajasthan. 200 pregnant women

with ≤12 weeks of gestation, who met the inclusion criteria, were included in the study.

The prevalence of thyroid disorders was 14% in present study. Many studies done in the past had similar results. Taghavi et al found 14.6% prevalence of thyroid disorders in their study. [6] Ajmani et al found 13.25% cases of thyroid disorders in their study. [7] Similarly, Weiwei Wang et al (10.2%), Sahu et al (12.7%) and Dhanwal DK et al (14.3%) had comparable results in their studies. [8-10]

The prevalence of thyroid disorder was very less (5%) in a study conducted by Thanuja PM et al [11], while the prevalence was very high (26.5%) in a study by Rajput et al [12], hence the results of these studies were in contrary with present study.

The prevalence of subclinical hypothyroidism in present study was 7%. In a study done by Sangeeta Palhwa et al, the prevalence of subclinical hypothyroidism was 6%. [13] Similarly, in a study by Sahu MT et al, the prevalence was 6.47% which is also comparable to our study. [9]

All women who have been diagnosed subclinical hypothyroidism during pregnancy should be tested for antithyroid antibodies because it can be associated with other autoimmune disorders like type I diabetes and can have adverse fetomaternal outcome. [14,15] ATA updated its guidelines in 2017 for the management of thyroid disorders in pregnancy. They suggested that Thyroxine should be started if antithyroid antibodies are present and initial level of TSH is 2.5- 4 mIU/L. If initial TSH level is > 4mIU/L, then Thyroxine should be started irrespective of the status of antithyroid antibodies. Usually the Thyroxine is started in the dose of 50 microgram per day to treat subclinical hypothyroidism and thyroid function tests are repeated after 4 weeks of starting treatment. [16, 17]

The prevalence of overt hypothyroidism in present study was 2%, which was consistent with the results obtained by Saraladevi et al with the prevalence of 2.8% [18] and partly consistent with the results obtained by Sahu MT et al, in which the prevalence was 4.58%. [9]

In present study, prevalence of subclinical hyperthyroidism and overt hyperthyroidism were 3% and 0% respectively. The prevalence of subclinical and overt hyperthyroidism was 0.5 and 0.4% respectively in the study done by Stagnaro Green A. [17] Similarly in the study done by Saraladevi et al the prevalance were 1.8% and 0.6% respectively. [18]

Our study had few limitations that fetomaternal outcomes were not included in the study. The sample size was also small. Hence, further researches with large sample size are advisable.

CONCLUSION

The study revealed high prevalence of thyroid disorders (14%) among pregnant women in their first trimester specially hypothyroidism (11%). Hyperthyroid disorders are rare in pregnant women. Due to immense impact of thyroid disorders on the fetomaternal outcome, we advocate the routine antenatal thyroid screening.

Postpartum Thyroiditis

SUDHA SHARMA*, D C SHARMA**

POSTPARTUM thyroiditis (PPT) is a syndrome of thyroid dysfunction that follows parturition within a year. In a typical case, transient thyrotoxicosis with low radioactive iodine uptake (RAIU) occurs within a few months after delivery and is followed by a period of hypothyroidism of several months duration with eventual return to euthyroid state. Spontaneous recovery occurs in most patients, but recurrence is experienced by many patients after 2-4 years[1].

PREVALENCE:

The prevalence of postpartum thyroiditis reported from different parts of world varies from 5.5-21%[2-4]. In a recent study a prevalence of 13% has been reported from India[5]. The variability in prevalence could be due to differences in the distribution of environmental or genetic risk factors.

CLINICAL FEATURES:

The spectrum of clinical presentation varies from a characteristic course of three sequential phases, the thyrotoxic phase, hypothyroid phase and recovery phase, to thyrotoxicosis alone or hypothyroidism alone[3]. Transient thyrotoxicosis generally occurs 1-3 months after parturition and lasts for 1-2 months. About one half of these patients return to euthyroid phase and remain so at least for some time. In the remaining half a hypothyroid phase that varies in duration from about 2-9 months develops 3-6 months after delivery. Almost all patients return to euthyroid state.

In majority of the patients symptoms are often mild and non-specific with fatigue being a prominent feature of both the thyrotoxic and hypothyroid phase. Examination reveals that thyroid gland is enlarged in only 50% of cases and is not associated with pain and tenderness. Enlargement is usually mild and not accompanied by nodularity[3].

Women with long-standing goitre and/or serum antithyroid antibodies during pregnancy or after delivery are more likely to develop PPT[2]. Lymphocytic infiltration is the most prominent pathological feature[6]. In addition to these changes certain other changes in the lymphocytes suggest that PPT is an auto-immune disease[6]. PPT has also been reported in patients with other autoimmune thyroid diseases like Hashimoto's thyroiditis and Graves' disease. There is strong association with the HLA-DR3 and HLA-DR5 haplotypes[6], which are also associated with atrophic and goitrous varieties respectively, of the Hashimoto's thyroiditis. The postpartum occurrence of the disorder is probably due to rebound of immune activity after its suppression during pregnancy[7].

Transient thyrotoxic phase is a result of sudden, uncontrolled release of preformed hormone because of loss of tissue integrity. Such forms of thyrotoxicosis due to thyroiditis is referred to as 'destruction induced' or 'thyrolytic hyperthyroidism'[8]. It is postulated that the iodine status of thyroid at the time of immunological injury may modify the clinical expression of the disorder[10]. Thus in iodine deficiency areas it is possible that an insufficient amount of thyroid iodine and thyroxine are leaked out during the destructive phase to produce thyrotoxicosis in these patients. Consistent with this view one study from India reported the finding of hypothyroidism as the sole manifestation of PPT[5].

RECURRENCE:

As the vague symptoms are generally present in most

Key words:
Gestational Diabetes, perinatal, glucose challenge, macrosomia

ABSTRACT

Objective: the study was conducted to diagnose the gestational diabetes mellitus (GDM) in early pregnancy using glucose challenge test (GCT) and glucose tolerance test (GTT) and to find out the prevalence of GDM in southern part of Rajasthan and fetomaternal outcome in those GDM patients.

Material and Methods: It was a prospective study carried out in the department of Gynaecology and Obstetrics of a tertiary healthcare centre during the period of 2 years from January 2017 to January 2019. 700 random pregnant women with 18-28 week of gestation were subjected to 50 gram GCT. Women with abnormal GCT were then subjected to 75 gram 2 hour GTT test. Patients were followed up till delivery and perinatal and maternal status were recorded.

Results: The age of the study participants ranges from 18 to 36 years with the mean age of 24±3 years while the mean age of GDM diagnosed women was 28.3±2 years. Out of 700 pregnant women included in the study, 67 women were found to have abnormal GCT and 27 women (3.8%) out of these 67 were found to have abnormal OGTT and were diagnosed with GDM. Most of the GDM patients were having plasma glucose level between 166-175mg/dl (33.33%) followed by 155—165mg/dl (29.62%). There was no fetal loss, no congenital abnormalities; no birth asphyxia in any of the newborns of GDM diagnosed women. 4 out of 27 newborns had macrosomia (weight >4kgs) and 3 newborns had IUGR (weight < 2.5kgs). Mean birth weight was 2.67 kgs.

Conclusion: prevalence of GDM in present study was 3.8%. Routine screening of pregnant women before 28 week of gestation with GCT and GTT should be performed because it is an easy, economical and patient friendly test. Prompt diagnosis and early management can improve maternal and perinatal outcome.

INTRODUCTION

Gestational Diabetes Mellitus (GDM) is defined as any degree of glucose intolerance with the onset of pregnancy or first recognized during pregnancy. [1] Women with history of GDM are at an increased risk of adverse fetomaternal outcome and also at increased risk of future diabetes, predominantly type II including their children. [2] Therefore it is important to diagnose the GDM as early as possible to prevent adverse fetomaternal outcome and complications.

There are many controversies regarding methods of screening and diagnosis of GDM and their cost-effectiveness. Precise level of glucose intolerance which characterizes GDM has also been controversial over past few decades. In 1964, O'Sullivan and Mahan performed study on 752 pregnant women and suggested the use of glucose values in diagnosis of GDM after 3 hour 100 gram oral glucose tolerance test (OGTT).[3]

Corresponding author:* **Dinesh Chandra Sharma
Department of General Medicine, Ananta Institute of Medical Sciences, Rajsamand

This diagnostic criteria was further modified by National Diabetes Data Group Criteria (NDDG) in 1979 by adjusting diagnostic thresholds upward.[4] This NDDG thresholds were adopted and recommended by American Diabetes Association (ADA) as diagnostic cut-off points for GDM until 1999.[5]

In 2000, ADA revised the recommendation for GDM diagnostic criteria and proposed adoption of Coustan and Carpenter Criteria (CCC) thresholds instead of NDDG thresholds.[6]

The International Association of Diabetes and Pregnancy Study Groups (IADPSG) in 2010 decided to use mean values of fasting, 1 hour and 2 hour blood glucose of all pregnant females as reference and chose to use odds ratio of 1.75 to define the diagnostic cut-offs for GDM, which led to the development of the widely used and accepted IADPSG criteria. [7]

Still there are some controversies regarding screening of pregnant women for GDM. The ADA recommends selective screening for GDM in pregnant women who are at high risk,

while other guidelines, including those of American College of Obstetrics and Gynecologists (ACOG), support screening of all pregnant women for GDM.[8, 9] The present study used the IADPSG criteria (2010) for diagnosing GDM in which fasting OGTT was performed with 75 gram glucose and if fasting plasma glucose (FPG) is ≥126 mg/dl, overt diabetes is diagnosed and if FPG is < 126 mg/dl, then GDM is diagnosed if any one of the values exceeds the threshold shown below:

	Fasting	1 hour	2 hour
Plasma Glucose (mg/dl)	≥92	≥180	≥153

The variation in prevalence of GDM worldwide depends on various screening and diagnostic methods used as well as on age and ethnicity of the pregnant women of the particular region.[10-16] The OGTT is usually performed between the 24th and 28th week of gestation; however, in women with associated risk factors like previous gestational diabetes or family history of diabetes, OGTT should be performed earliest soon after diagnosis of pregnancy.[16] Early screening can avoid serious complications in women with GDM.[17]

The present study is aimed to find out the prevalence and diagnosis of GDM in southern part of Rajasthan with the use of GCT and OGTT and fetomaternal outcome in the patients of GDM .

MATERIAL AND METHODS

The present study was a prospective study carried out in the department of Gynaecology and Obstetrics, Ananta institute of medical sciences, Rajsamand during the period of 2 years from January 2017 to January 2019.

700 pregnant women with gestation of 18-28 week were randomly recruited from the antenatal clinic of our institute. All the 700 women were given 50 gram glucose load for glucose challenge test (GCT) without regard to the time of last meal and the venous blood samples were collected after 1 hour for estimating plasma glucose. GCT was marked abnormal if 1 hour plasma glucose was > 140 mg/dl (7.77 mmol/L).

All the women with abnormal results were then subjected to 2 hour 75 gram oral glucose tolerance test (OGTT) for confirmation. In OGTT, initial blood sample was taken after overnight fasting and the patient was then asked to drink solution of 75 gram glucose in 200 ml water. If fasting plasma glucose (FPG) was ≥126 mg/dl, overt diabetes was diagnosed and if FPG was < 126 mg/dl, then GDM was diagnosed if any one of the values exceeds the threshold as shown below:

	Fasting	1 hour	2 hour
Plasma Glucose (mg/dl)	≥92	≥180	≥153

Patients were followed up till delivery and maternal and perinatal status was recorded.

RESULTS

The age of the study participants ranges from 18 to 36 years with the mean age of 24±3 years.

Out of 700 pregnant women included in the study, 67 women were found to have abnormal GCT and these 67 women were then subjected to 2 hour, 75 gram OGTT. 27 women (3.8%) out of 67 were found to have abnormal OGTT and were diagnosed with GDM. The mean age of the GDM diagnosed women was 28.3±2 years.

Most of the GDM patients were having 2 hour plasma glucose level between 166-175mg/dl (33.33%) followed by 155—165mg/dl (29.62%). (Table 1)

Table 1 Range of plasma sugar level in GDM patients

Plasma sugar level (mg/dl)	Number of patients	Percentage
155-165	8	29.62
166-175	9	33.33
176-185	7	25.92
>185	3	11.11
Total	27	100%

There was no fetal loss, no congenital abnormalities; no birth asphyxia in any of the newborns of GDM diagnosed women. 4 out of 27 newborns had macrosomia (weight >4kgs) and 3 newborns had IUGR (weight < 2.5kgs). Mean birth weight was 2.67 kgs.

DISCUSSION

The worldwide prevalence of gestational diabetes ranges from 1-14%. [18, 19]

In India, prevalence rates reported to be between 4.6% and 14% in urban areas, and 1.7% and 13.2% in rural areas. [20]
In present study, the overall prevalence of GDM was 3.8%. The figure was comparable to the studies done in the past by Indian workers like Maheshwari *et al* and Kumar *et al* with the prevalence of GDM 4.9% and 5.5% respectively. [21, 22]

The mean age of all study participants in present study was 24±3 years while the mean age of GDM diagnosed women was 28.3±2 years. Similar results were obtained in the study by Ismail NA *et al* who reported the mean age of 27.9 years in GDM patients. [23] Hence increasing age of patient was significantly associated with GDM.

High perinatal mortality rate in uncontrolled GDM patients has been reported by O'Sullivan JB *et al* in 1973. [24] Similarly, Fareed P *et al* showed 9% perinatal mortality in GDM patients compared to 1% in control group. [25] The results were in contrary to the results of present study. In present study, there was no perinatal mortality and no congenital malformation was there. Mean birth weight of the newborns was 2.67 kgs. This could be made possible because of early screening for GDM and management of the patients.

4 out of 27 newborns (14.81%) had macrosomia (weight >4kgs) and 3 newborns (11.11%) had IUGR (weight < 2.5kgs). This observation was comparable to past studies done by Fareed P *et al*, Wahi P *et al* and Bener AB *et al* where macrosomia was found 17%, 16.2% and 10.3% respectively. [25, 26, 27]

CONCLUSION

The study concluded that the prevalence of GDM is 3.8% in southern area of Rajasthan. Increasing age of pregnancy is significantly associated with GDM. We advocate the routine screening of pregnant women before 28 week of gestation with 50 gram GCT because it is an easy, economical and patient friendly test as patient need not to come fasting for this test. Patients who have abnormal value in GCT should be subjected to GTT for confirmation of GDM. Prompt diagnosis and early management can improve maternal and perinatal outcome.

Postpartum Thyroiditis

JIMA (Special Article

SUDHA SHARMA*, D C SHARMA**

POSTPARTUM thyroiditis (PPT) is a syndrome of thyroid dysfunction that follows parturition, within a year. In a typical case transient thyrotoxicosis with low radioactive iodine uptake (RAIU) occurs within a few months after delivery and is followed by a period of hypothyroidism of several months duration with eventual return to euthyroid state. Spontaneous recovery occurs in most patients, but recurrence is experienced by many patients after 2-4 years[1].

PREVALENCE :

The prevalence of postpartum thyroiditis reported from different parts of world varies from 5.5-21%[2-4]. In a recent study a prevalence of 13% has been reported from India[5]. The variability in prevalence could be due to differences in the distribution of environmental or genetic risk factors.

CLINICAL FEATURES :

The spectrum of clinical presentation varies from a characteristic course of three sequential phases, the thyrotoxic phase, hypothyroid phase and recovery phase, to thyrotoxicosis alone or hypothyroidism alone[6]. Transient thyrotoxicosis generally occurs 1-3 months after parturition and lasts for 1-2 months. About one half of these patients return to euthyroid phase and remain so at least for some time. In the remaining half a hypothyroid phase that varies in duration from about 2-9 months develops 3-6 months after delivery. Almost all patients return to euthyroid state.

In majority of the patients symptoms are often mild and non-specific with fatigue being a prominent feature of both the thyrotoxic and hypothyroid phase. Examination reveals that thyroid gland is enlarged in only 50% of cases and is not associated with pain and tenderness. Enlargement is usually mild and not accompanied by nodularity[7].

Women with long-standing goitre and/or serum antithyroid antibodies during pregnancy or after delivery are more likely to develop PPT[6]. Lymphocytic infiltration is the most prominent pathological feature[6]. In addition to these changes certain other changes in the lymphocytes suggest that PPT is an auto-immune disease[6]. PPT has also been reported in patients with other autoimmune thyroid diseases like Hashimoto's thyroiditis and Graves' disease. There is strong association with the HLA-DR3 and HLA-DR5 haplotypes[8], which are also associated with atrophic and goitrous varieties respectively, of the Hashimoto's thyroiditis. The postpartum occurrence of the disorder is probably due to rebound of immune activity after its suppression during pregnancy[9].

Transient thyrotoxic phase is a result of sudden, uncontrolled release of preformed hormone because of loss of tissue integrity. Such forms of thyrotoxicosis due to thyroiditis is referred to as "destruction induced" or "thyrolytic hyperthyroidism"[6]. It is postulated that the iodine status of thyroid at the time of immunological injury may modify the clinical expression of the disorder[10]. Thus in iodine deficiency areas it is possible that an insufficient amount of thyroid iodine and thyroxine are leaked out during the destructive phase to produce thyrotoxicosis in these patients. Consistent with this view one study from India reported the finding of hypothyroidism as the sole manifestation of PPT[5].

RECURRENCE :

As the vague symptoms are generally present in most

A STUDY OF MATERNAL MORTALITY IN A RURAL MEDICAL COLLEGE, HOSPITAL

SUDHA SHARMA

SUMMARY

This study analysis maternal mortality, its causes & preventable factors during a period of 5 years from 1989-1993. There were 1751 births & 29 maternal deaths during this period making maternal mortality rate of 16.5/1000 births. Direct causes were responsible for 72.2% deaths. Haemorrhage was responsible for 27.5% deaths, sepsis for 20.6% and toxemia for 17.2% deaths. Indirect causes were present in 27.4% of deaths in the form of anemia 10.3%, malaria 10.3%, viral encephalitis and hepatitis 3.4% each. In 90-95% of maternal deaths preventable factors were present. This could have been done by proper ante and intra natal care, by correction of anemia and by providing effective blood transfusion services.

MATERNAL AND METHODS

The present study is a retrospective analysis of maternal deaths over a period of five year carried out in department of obstetric and Gynaecology of Pramukhswami Medical College, Karamsad, Gujarat. This institute is a rural medical college, mainly caters to illiterate, rural and low socioeconomic community. The aim was to find out various factors responsible for the maternal deaths and preventive measures if any.

The study was done from 1989-1993. During this period there were total 29 maternal deaths. Individual case papers of these patients were thoroughly scrutinised for full details about parity, antenatal booking, age of the patient, admission death interval and causes of deaths.

Dept. of Obst. & Gyn. P.S. Medical College, Karamsad, Gujarat.

Accepted for Publication on 21.07.1994.

OBSERVATIONS

In 5 years duration from 1989-1993 there were 1751 births and 29 maternal deaths giving the incidence of 16.5/1000 births.

All the patients except one were admitted as emergency cases. They all belonged to low socio economic group.

Table I shows agewise distribution of maternal deaths.

Table II shows distribution of patients on the basis of parity.

Table III shows the interval between admission and death.

Table IV shows causes of deaths.

Major cause of death was haemorrhage. As such direct causes were responsible for 72.2% deaths. Of the various causes of haemorrhage 37.5% were because of ante partum haemorrhage, 25% were due to postpartum haemorrhage. Ectopic pregnancy, inversion of uterus and disseminated intravascular coagulation contributed 12.5% each. Sepsis accounted for 20.6% of maternal deaths. 50% of it were due to pregnancy with septicemia, 33.3% were due to puerperal sepsis and

Table I

Age in years	No. of deaths	Percentage
Less than 20	3	10.6
20-30	20	66.9
> 30	6	20.6

Table II

Parity	No. of patients	Percentage
Primigravida	9	31.0
Multigravida	15	51.7
Grandmultipara	5	17.2

Table III

Admission to death interval	No. of patients	Percentage
< 24 hours	22	75.8
within a week	7	24.1

Table IV

Direct causes	No. of patients	Percentage	Indirect causes	No. of patients	Percentage
Haemorrhage	8	27.5	Anemia	3	10.3
Sepsis	6	20.6	Malaria	3	10.3
Toxemia	5	17.2	Viral encephalitis	1	3.4
Thromboembolism	2	6.9	Hepatitis	1	3.4
Total	21	72.2		8	27.4

Accepted

16.6% died because of septic abortion.

Toxemia attributed to 17.2% deaths. Out of these 4 cases had eclampsia and one had fulminant toxemia. 6.9% of deaths were accounted by thromboembolism.

In indirect causes anemia and malaria were responsible for 20.3%, one patient had viral encephalitis and another had hepatitis making 27.4% for indirect causes.

DISCUSSION

The present study showed a very high maternal mortality rate of 16.5/1000 births. Maternal mortality has been reported by various authors varying from 1.04/1000 births (Warawalla et al, 1989) to as high as 16.5 per 1000 births. This high incidence of maternal mortality could be due to multiple factors. As this institute is draining mainly poor and rural community, so unawareness about the antenatal care was the most important factor, as evident by the fact that none of the patients except one has received antenatal care. Though facilities for antenatal and intranatal care are present, most of the expectant mothers in rural community do not take advantage of these due to ignorance, carelessness, illiteracy, social and religious taboos.

Haemorrhage remained the commonest (27.5%) cause of death. Association of moderate to severe anemia contributed to increase in the risk from haemorrhage. Anemia was present in 84.5% of patients and it was the sole cause of death in 3 patients (10.3%). In other studies haemorrhage was responsible for deaths in 35.2% (Devi & Singh, 1987), 22.8% (Beebi,1987) and 35.6% Varawalla et al, 1989). In many cases non availability of blood at critical time was the cause of death.

Although the use of $MgSO_4$ has dramatically reduced deaths due to eclampsia, due to late referrals by the local village practitioners and ignorance on the part of relatives, most of the patients were received in a moribund condition. None of the patient had prior antenatal check up. These deaths could have been prevented by proper antenatal care and early hospitalization.

Sepsis claimed 27.5% of deaths in this study as compared to 7% (Devi & Singh, 1987), 12% (Beebi, 1987) & 3.3% (Varawalla et al, 1989) deaths reported in different studies.

CONCLUSIONS

It can be assumed that most of the maternal deaths could have been prevented but had occured as a result of negligence on the part of the patients, their relatives and local practitioners. For prevention specially in India, there is an urgent need for proper implications of existing health programmes in rural areas. For improvement of the female health status it is necessary to give them health education, knowledge of hygiene and importance of antenatal care and complications of pregnancy. Many deaths can be prevented by early and proper antenatal care, avoidance of unwanted and repeated births, training of traditional birth attendants and refresher courses for village medical practitioners and timely available facilities for blood transfusion.

4. *Varawalla N.Y., Kelkar G., Dhurandhar J.K. and Ingle K.M. : J. Obstet. Gynec. India : 39;509;1989.*

Deaths due to anemia and sepsis along with hemorrhage, DIC, anesthesia difficulties/complications, and nonavailability of ICU bed are considered potentially preventable causes and accounted for 25.38% (33/130) of all deaths.

Conclusion

The classical triad of causes of maternal mortality in our study remained sepsis, eclampsia, and hemorrhage, in the same order. According to the WHO report (2005) "make every mother and child count" hemorrhage is the leading cause of death. Sepsis and hemorrhage deaths are considered one of the potentially preventable causes of MDs.

The present study highlights the importance of early antenatal registration of all pregnancies and regular follow-up of cases by trained staff. Poor nutritional status, lack of antenatal care, unawareness of warning signs of pregnancy, unsupervised dai-handled deliveries, social bias toward blood donation, and late referrals are the major contributory factors leading to poor maternal prognosis.

The lessons learnt through review of records of MDs have helped us to identify the high-risk group, solely for the purpose of improving service-delivery system by ascertaining the cause of death, reason(s) for inability to provide appropriate care at appropriate time, and finding the key interventions at service-delivery level to prevent similar deaths. There should be active management of high-risk group by frequent ANC visits, direct consultant supervision, liberal use of CTG, color Doppler study, biochemical markers, fluid and component transfusions, aggressive management of infection, and closer monitoring of women in labor. Vigorous mass campaign for community-based maternal education program should be the top priority of all maternal and child health programs.

MATERNAL AND NEONATAL ANEMIA AND IRON STATUS IN URBAN, RURAL AND TRIBAL POPULATION OF UDAIPUR

DINESH C. SHARMA, SUDHA SHARMA, VINAYA PENDSE AND PREM P. SINGH

(Departments of Biochemistry and Obstetrics and Gynaecology, R.N.T. Medical College, Udaipur - 313 001)

(Received 1st December, 1994)

Introduction

Anemia, especially due to iron deficiency, is a major public health problem throughout the world, because of high morbidity rate, its effect on work performance and immune function of the afflicted person, and on growth and mental development of the children, and high mortality during pregnancy and childhood[1]. Anemia is also widespread in India[4] and its prevalance is reported to be higher in females than in males and more in infants and children than in adults[2]. Therefore, it was considered pertinent to know how far the anemia and iron deficiency in newborn was as a consequence of maternal anemia and iron deficiency. Such studies have been done in the past but the results were conflicting. Some workers found that maternal iron deficiency did affect neonatal iron status[3-7]. While there were others who did not concur[8-12]. The present study was, therefore, aimed to re-examine the maternal-foetal relationship with respect to severity of anemia of the mother using all the red cell indices as well as iron status parameters.

Materials and Methods

The subjects of this study were parturient women admitted to the labor room of Zannana Hospital, Udaipur for delivery during July 1989 to September 1990. Only those cases were included who were free from infection and inflammation and had normal spontaneous delivery without any complications. These were selected solely on the basis of their hemoglobin level and were grouped into four : Group I ; non-anemic, Hb> 10 g/dl ; Group II, mild anemia - Hb 8.1 to 10 g/dl ; group III, moderate anemia - Hb. 6.1 to 8g/dl ; and Group IV, severe anemia - Hb < 6g/dl. The number of cases in each of the four groups was twenty.

Blood sample of mother was taken at the time of delivery, while cord blood was collected for the blood of newborn. The details are given in the earlier publication[3]. Hemoglobin (Hb), total red blood cell count (TRBC), packed cell volume (PCV), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), and mean corpuscular hemoglobin concentration (MCHC) were determined as described in another paper[13]. The estimation of serum iron (SI), total iron binding capacity (TIBC) and transferrin saturation or percent saturation (PS) was done as reported in our recent report. Unpaired student's 't' test was applied to statistically evaluate the difference of values between the two groups and correlation coefficient (r) was calculated to establish the correlation between two parameters[14].

Results and Discussion

The maternal hematologic and iron values in the four groups is given in Table I. It can be seen that, except TIBC, there was progressive fall in all the values as the severity of anemia increased. On statistical evaluation of data the values in each group were found to be significantly different. An examination of red cell indices indicated the presence of microcytic hypochromic anemia in most of the mothers suggesting iron deficiency as the cause of anemia which conclusion is supported by SI, PS and TIBC values. As PS is also an indicator of storage iron the alarmingly low values indicate iron deficiency as a serious public health problem in some of the pregnant mothers of this region[15].

The hematologic values of the newborns were also significantly lower in anemic groups when compared to nonanemic group, except TIBC, which was increased (Table I). A progressive decline in these values was noted with the severity of anemia of mother. When the observed red cell indices were compared with normal values quoted in a standard Textbook of Pediatrics[16] many newborns were found to have values lower than lowest value of the normal range. This is especially evident in case of MCHC, MCH or TRBC than Hb. The red cell indices suggested that many babies had normocytic hypochromic anemia even at the time of birth. Serum iron of many was below normal range of neonates[16]. All these observations point to existence of iron deficiency and iron deficient erythropoiesis in the newborns. This means that iron deficiency in the mother not only affects her own iron status but also her newborn baby, albeit to a lesser extent. This is despite the fact that foetal tissues get priority over maternal requirements. The failure of those workers who reported contrary to it was partly due to use of only a single criteria (e.g. Hb), selection of cases of less severe form of anemia and faulty comparison of neonatal values with the adult values.

A significantly lower value of transferrin saturation in newborns of anemic mothers mean they are endowed with significantly lower iron stores at time of birth. So many of them may develop anemia in infancy or childhood, if not already present. A confirmation of this possibility has been published[5]. In this study, indirect confirmation of the observation that maternal iron deficiency anemia and iron status did affect foetal iron status, was provided by correlation between maternal and foetal Hb, SI and PS values. A significant correlation was found between maternal SI and neonatal SI ($r = 0.407$; $P < 0.001$) and Hb ($r = 0.362$; $P < 0.001$), maternal PS and neonatal SI ($r = 0.504$; $P < 0.001$) and Hb ($r = 0.569$; $P < 0.001$) and maternal Hb and neonatal Hb ($r = 0.468$; $P < 0.001$) indicating that neonatal Hb and SI values are dependent upon maternal SI values on which also depends maternal Hb value and that storage iron of mother (as reflected by maternal PS) also affects newborn's hemoglobin and serum iron.

Such low hematologic and iron values may seem unusual in the West, but in India these are not uncommon. The reasons are numerous but are different for different population groups. The subjects of this study actually belonged to urban, rural or tribal population and area. It was seen that hemoglobin and iron status of urban women, and the worst was in case of tribal women (Table II). It may be because urban women generally had awareness about hygiene and antenatal care, were having small families, better educational background, better socioeconomic status and hence better nutrition, than their counterparts in rural and tribal area. The main cause of iron deficiency and consequent anemia in them was poor bioavailability of non-heme iron from cereal based predominantly vegetarian diet. This aspect has been discussed in detail in another paper currently under publication[17]. Rural women had moderate anemia and lower iron status because of additional factors like repeated pregnancies and parasitic infections. Frequent attacks of

All values are mean ± SD

malaria may also have contributed to anemia. The main cause of severe anemia and iron deficiency in the tribal women is appalling poverty (income - less than Rs.200/- per capita per month), undernutrition, diet inadequate in calories (less than 1000 calories/day) as well as protien and other hematopoietic nutrients, unhygienic conditions, frequent attacks of diarrhoea and malaria, parasitic infestations, and of course, repeated pregnancies with short spacing and prolonged lactation period.

As all the women were prescribed calcium and iron-folic acid tablets in antenatal clinic it was considerd desirable to see the impact of antenatal checkup and advise on iron status and blood picture. There was a highly significant difference ($P < 0.001$) between all the parameters of booked and unbooked cases confirming better iron status of the mothers who had attended the antenatal clinic as well as their newborn babies (Table II). As this study specifically selected cases of anemia, the women who had benefitted most from antenatal services were excluded. However, it must be admitted that the iron status of some of the women, who had attended the antenatal clinic, as well as their newborns, was far from satisfactory (Table II). The poor iron status of these women is intriguing. It is believed that the reasons are dietary in origin. The intake of iron in the cereal based predominantly vegetarian diet is twice the intake of iron by people of western countries consuming predominantly meat group of foodstuffs[17,18].

Thus their diet was actually not deficient in iron, hence iron supplementation did not improve iron status. Perhaps what was lacking was ascorbic acid (a potent promoter of iron absorption) and protein because consumption of citrus fruits was negligible[19] and vegetarian food is poor in quality of protein[19]. Hence, it may be more sensible to prescribe during antenatal period a nutrient which is actually deficient, i.e. ascorbic acid or protein, rather than one which is quite adequate or to recommend animal food items like, meat, liver, fish and poultry to improve iron status and correct the anemia.

Summary and Conclusion

The hematologic and iron status parameters were determined in the parturient women with varying degree of severity of anemia and their new borns. It was found that the urban, rural and tribal women exhibited anemia and iron deficiency in increasing order of severity and that the maternal iron deficiency and anemia affected red cell indices and iron status of the neonate. In general, women who had received antenatal services, as well as their newborns, had better hematologic and iron status, yet it was far from satisfactory in some of them, presumably due to consumption of cereal based predominantly vegetarian diet, rich in iron, but poor in ascorbic acid and protein. It is, therefore, suggested that supplementation of ascorbic acid during antenatal period may be more beneficial than giving iron tablets/tonic.

ABSTRACT

Background: To achieve the goal of Millennium Development Goal 2 (universal education), 3 (gender equality and women empowerment) and, 5 (improving maternal health), it is important that there is effective menstrual hygiene and knowledge among adolescent girls since it has direct and indirect effects both to achieve the MDG and to promote the reproductive health. A study was carried out among the school going adolescents in UHTC (Urban Health Training centre) and RHTC (Rural Health Training centre) area of Department of Community Medicine, Government Medical College, Kota, Rajasthan with the following aims and objectives, Status of knowledge of school going adolescent girls about menstruation and their practice during menstruation. The objective of the study was to assess the knowledge and practices regarding menstruation among school going adolescents.

Methods: It was a school based descriptive cross sectional study conducted from November 2016 to March 2017. The school was selected randomly in RHTC and UHTC area of GMC, Kota. A pretested and structured questionnaire was used. Data was entered, processed and analyzed using SPSS version 20.

Results: In this study there were 300 girl students (150 each from RHTC and UHTC area schools), of which 55.33% had menarche at the age of 13 years, 66.00% of girls were aware about menstruation before the menarche whereas 91.67% of girls heard about the sanitary napkins, most of the girls (81.00%) had got the knowledge about menses from their mother, 62.67% of girls heard about the menstrual hygiene and for practices observed, 65.67% girls were using sterilized sanitary napkins and 42.00% of girls burn the waste material.

Conclusions: Traditional beliefs regarding menstruation still persist and menstrual hygiene among the adolescents was found to be unsatisfactory. It highlights the need of targeted interventions to raise awareness and provision of family health education package to all girls. Menstrual hygiene is an issue that needs to be addressed at all levels.

INTRODUCTION

Adolescents are a large and growing segment of the world's population where more than half of the world's population is below the age of twenty five defined as a period of life between 10–19 years.[1] According to UNICEF report (The State of World's Children 2011), it is estimated that there are 1.2 billion adolescents aged 10-19 years in the world, forming 18% of world population and about 88% of them live in developing countries. In India, adolescent accounts for 20% of countries population. It is a highly dynamic period characterized by

With Water	39 (26.00)	60 (40.00)	91 (30.33)
With Soap	111 (74.00)	90 (60.00)	201 (67.00)

*Multiple responses, total not additive

The average age of menarche came out to be 12.99 ± with more than half of the participants (55.33%) having menarche at the age of 13 years followed by (25.67%) for 14 years and the least 0.33% at the age of 9 years. Difference in age of menarche between rural and urban area was insignificant ($p<0.01$) (Table 2).

When we saw for the knowledge of girls regarding the menstruation, we found that 66.00% of girls were aware about menstruation before the menarche, 91.67% of girls had heard about the sanitary napkins. Most of the girls (81.00%) had got the knowledge about menses from their mother, 52.33% of girls got the knowledge from mass media. On the other hand 62.67% of girls had information about menstrual hygiene and 43.33% of girls were aware about RTI / STI (Table 3).

When we saw for practices among adolescent girls, there were 65.67% girls were using sterilized sanitary napkins while rest of the study subjects were using cloths, 73.00% girls had the complaint of pain during menstruation and 39.67% had irregular menstruation while 54.00% of girls had restriction for kitchen activity due to social customs in their home. When we enquired about the disposal practices of sanitary napkins / pads, 42.00% of girls burn the waste material followed by 28.67% for open area disposal, on the other side 46.00% of urban girls and only 06.00% of rural girls use municipal dustbins (Table 4).

ABSTRACT Pelvic organ prolapse in rural and tribal population is major health disability in perimenopausal and post menopausal women(1).The disorder accounts for 20% of women waiting for major gynaecological surgery.(2) The Prevalence of pelvic floor dysfunction was reported to be 21% with 19.02% of the women experiencing urinary incontinence (3) Present study has been conducted on 1267 patients who have undergone vaginal hysterectomy with pelvic floor repair at PIMS UMARDA UDAIPUR in the last three years. Age, parity, low socioeconomic status, anemia, repeated vaginal deliveries, squatting all day chronic cough and manual labor and strenuous farming have been major causes. Vaginal hysterectomy with pelvic floor repair treats 90% of the disability.Aim of present study is to study causes suggest preventive aeps and to evaluate the results of surgery

KEYWORDS : Urinary incontinence, Pelvic floor dysfunction. Pelvic organ prolapsed, utero vaginal prolapse, cystocele, rectocele, enterocele, pelvic floor repair, vaginal hysterectomy

INTRODUCTION

Pelvic Floor Dysfunction including pelvic organ prolapse is one of the largest unaddressed issues in women's health care today (4). It is common and undermines the quality of life (5). Patients with pelvic floor dysfunction usually present with symptoms of incontinence which can be either urinary or anal, pelvic organ prolapse or dysfunctional bowel. It is rarely life threatening, but the symptoms can be embarrassing and, if left untreated, it can lead to social isolation, sexual inhibition, restricted employment and leisure opportunities and potential loss of independence. The women consider pelvic floor dysfunction as a normal part of the aging process and not as a disease/disorder and this is one of the reasons for not seeking medical treatment. The other reasons for non-consultation are fear of hospital visits, investigations and surgeries, lack of money/time, shyness to report issues related to reproductive system, lack of female doctors in the rural setup and dependency on their husband for treatment in terms of permission, escort and finance (6)

Uterine-prolapse is the herniation of the uterus into or beyond the vagina as a result of failure of the ligamentous and fascial supports. It often coexists with prolapse of the vaginal walls, involving the bladder or rectum(9) The Oxford Family Planning Association study reveals Level 1: The cardinal-uterosacral ligament complex provides apical attachment of the uterus and vaginal vault to the bony sacrum. Uterine prolapse occurs when the cardinal-uterosacral ligament complex breaks or is attenuated. Level 2: The arcus tendineous fascia pelvis and the fascia overlying the levator ani muscles provide support to the middle part of the vagina. Level 3: The urogenital diaphragm and the perineal body provide support to the lower part of the vagina.(7) the risk factors include Older age, Race, Family history, Increased body mass index, Higher parity, Vaginal delivery Constipation Intrapartum variables (macrosomia, long second stage of labour, episiotomy, epidural analgesia) Increased abdominal pressure and Menopause. Although vaginal delivery is clearly associated, specific obstetric risk factors remain controversial. Macrosomia, prolonged second stage of labour, episiotomy, anal sphincter injury, epidural analgesia, and the use of forceps and oxytocin have all been proposed as risk factors but have not been proved (8). Conservative treatment includes Pelvic floor muscle training and vaginal pessary. Definitive surgery is vaginal hysterectomy with pelvic floor repair (9)

MATERIALAND METHODS

Present study has been undertaken to determine the predisposing factors in development of pelvic organ prolapse and to suggest preventive measures. Further it is aimed at analysising the results of surgery. Study has been carried out at PACIFIC INSTITUTE OF MEDICAL SCIENCES UMARDA UDAIPUR RAJASTHAN. Maximum patients are tribals of south rajasthan and are very poor and malnourished. these women are married at early age have repeated pregnancies and vaginal deliveries by untrained dias putting lots of pressure no episiotomy .They usually squat all day and for toilets. They suffer from chronic cough due to smoke in kitchen OR bidi smoking and high prevevalance of tuberculosis. They can easily hide prolapsed in loose clothings. Period of study has been 2014 to 2017. Maternal age, parity, education, socio-economic status, type of delivery was in recorded. Pre-existing maternal disease, chronic cough anemia, was recorded. Maternal weight obstetric complications, tobacco use were recorded. Symptoms are recorded. Sensation of a bulge or protrusion seeing or feeling a bulge Pressure AND Heaviness Urinary symptoms include Incontinence, frequency, or urgency. There is Weak or prolonged urinary stream and Feeling of incomplete emptying. Manual reduction of prolapse is needed to start or complete voiding ("digitation") Change of position needed to start or complete voiding. Bowel symptoms include, Incontinence of flatus, or liquid or solid stool Feeling of incomplete emptying, Straining during defecation and Digital evacuation needed to complete defecation. Splinting (pushing on or around the vagina or perineum) needed to start or complete defecation ("digitation") Sexual symptoms include Dyspareunia (painful or difficult intercourse) Lack of sensation. Examination includes local, per speculum and per vaginal examination to degree of prolapsed. Any bleeding or discharge per vagina were recorded. General examination includes weight, anemia and blood pressure. Laboratory studies, hemoglobin, leukocyte count, blood sugar, urea, keratinize; liver enzymes, urine albumin and sugar were recorded. Imaging studies, x-ray chest and ultrasonography were recorded. A pelvic examination should be done (using a Sim's single bladed speculum) to define the extent of the prolapse and establish the compartments of the vagina affected (anterior, posterior, or apical). The patient should be at rest and straining during a Valsalva manoeuvre. The oestrogen status of the tissues (signs of vaginal atrophy) and the size and mobility of the uterus and adnexae should be assessed. Stage 0: No prolapsed Stage I: The most distal portion of the prolapse is >1 cm above the level of the hymen Stage II: The most distal portion of the prolapse is ≤1 cm proximal or distal to the hymen Stage III: The most distal portion of the prolapse is >1 cm below the hymen but protrudes no further than 2 cm less than the total length of the vagina Stage IV: Complete eversion of the vagina They were followed post operatively with regard to symptom relief and anatomical correction was analysed after eight weeks and at 6 months

Abstract

Maternal mortality ratio in India is 199per 100000 births, MMR in Rajasthan is 208 per 100000 live births and MMR in Udaipur is 284 per 100000 live births (2016) [1]. Leading causes include post partum hemorrhage (30%), sepsis, unsafe abortions, rupture of uterus and obstructed labor [2]. Emergency hysterectomy in obstetrics is rarely indicated and is always debatable but if performed timely and wisely can be life saving [3]. In the present study 24 cases (92.30%) belonged to age group of 26-35 years. 22cases (84.61%) belonged to Para 3 and 4. 14 cases (53.84%) required emergency obstetric hysterectomy to control atonic post partum hemorrhage . 6 cases (23.07%) were due to rupture of uterus , 4 case (15.38%) was due to sepsis 1 case due to cervical ectopic pregnancy. 20(76.92%) were unbooked cases with no antenatal care. There was no maternal mortality. Aim of the present study is to help reducing maternal morbidity and mortality and to suggest ways of improving maternal outcome.

Keywords: Obstetric hysterectomy, Emergency hysterectomy, Rupture uterus, Trauma to uterus, Septic abortion, Post partum hemorrhage.

Emergency hysterectomy has been considered as life saving procedure in obstetric hemorrhage since last 200 years [4]. With advent of potent drugs like prostaglandins, oxytocin, ergotamine, hemocoagulase (botroclot), tranexemic acid, blood transfusion and antibiotics, the requirement of obstetric hysterectomy has been brought down considerably [5]. Conservative approach like internal iliac artery ligation, hemostatic sutures on uterus, embolisation of uterine artery, is quite effective when ever available. Inspite of all this progress emergency hysterectomy still remains the life saving procedure and for better results it should be timed well and not done as last resort [6]. Post-partum hemorrhage remains an important cause of significant maternal morbidity and mortality throughout the world [7]. Uterine rupture is associated with clinically significant uterine bleeding, fetal distress, expulsion or protrusion of the fetus, placenta or both into the abdominal cavity, and the need for prompt cesarean delivery and uterine repair or hysterectomy [8]. The risk factors for rupture include previous cesarean sections, multiparity, malpresentation and obstructed labor, uterine anomalies and use of prostaglandins for however, the most commonly associated risk factor. The most consistent early indicator of uterine rupture is the onset of a prolonged, persistent, and profound fetal bradicardia. The signs and symptoms of uterine rupture are typically nonspecific, which makes diagnosis difficult. Delay in definitive therapy causes significant fetal morbidity. For the best outcome, vaginal birth after previous cesarean section needs to be looked after in an appropriately staffed and equipped unit for an immediate cesarean delivery and advanced neonatal support [9].

This is a prospective observational study done in a Tertiary Care Center, hospital of PIMS (PACIFIC INSTITUTE OF MEDICAL SCIENCES, VILLAGE UMARDA, UDAIPUR, RAJASTHAN from 2014 to 2019. Women who underwent emergency peripartum hysterectomy after cesarean delivery or following vaginal birth due to severe post-partum hemorrhage and who did not respond to conservative treatment were included in the study. Primary outcomes included indications, risk factors, maternal morbidity, and mortality. Age, parity, socioeconomic status, education

Complains and details of illness, obstetric history, medical and surgical history was noted. General examination included presence of anemia, blood pressure and edema. Systemic examination included cardiac and lung condition. Uterine height, presentation, position, contraction were noted. History of bleeding per vagina was recorded. Ultrasonic examination results were recorded. Blood HB, SUGAR, UREA, CREATININE, BLOOD COUNTS, BT, CT, PT, HIV, HBSAG VDRL, URINE SUGAR and ALBUMIN, BLOOD GROUPING results recorded. INDICATIONS, RISK FACTORS AND OUTCOME of emergency obstetric hysterectomy were recorded.

Table-1: Age distribution of cases of emergency obstetric hysterectomy

S.No	Age In Years	No Of Patients	Percentage
1	Less than 20	0	0
2	20-25	0	0
3	26-30	10	38.46
4	31-35	14	53.84
5	More than 36	2	7.70
		26	100

Table-2: Parity distribution of cases of emergency obstetric hysterectomy

S. No.	Parity	Number	Percentage
1	0	0	0
2	1	0	0
3	2	0	0
4	3	14	53.84
5	4	8	30.76
6	5	4	15.40
		26	100

Table-3: Risk factors of emergency hysterectomy

S. No	Risk Factors	No	Prcentage
1	Pregnancy induced hypertension	20	76.92
2	Anemia	18	69.23
3	Ante partum hemorrhage, accidental and placenta previa	4	15.38
4	Post caesarean pregnancy	6	23.07
6	Twins	1	7.70
7	Induction of labor	4	15.38
8	Un Booked cases with no antenatal visits	20	76.92

Table-4: Indications of emergency obstetric hysterectomy

S.No	Indications	Number	Percentage
1	Atonic post partum hemorrhage		
	Normal vaginal delivery	2	7.70
	Caesarean delivery	4	15.40
2	Rupture uterus		
	Post caesarean preg		
	Misuse of oxytocic	4	15.40
	spontaneous	2	7.70
	Unscarred uterus		
	spontaneous	2	7.70
	Misuse of oxytocic	2	7.70
3	Placenta praevia	2	7.70
4	placenta acreta	2	7.70
5	Septic abortion	4	15.40
6	Cervical ectopic pregnancy bleeding	2	7.70
		26	100

24 cases (92.30%) belonged to age group of 26-35 years 22 cases (84.61%) belonged to Para 3 and 4. 20(76.92%) had pregnancy induced hypertension,18(69.23% had anemia, 4(15.38%) and ante partum hemorrhage, 6(23.07) were post caesarean pregnancies.1(3.84%) were twins and 4(15.38%) induced patients 14 cases (53.84%) required emergency obstetric hysterectomy to control uterine bleeding. 10 cases (38.46%) were rupture of uterus due to misuse of oxytocics and 2case (7.70%) were due to sepsis.

Fig-1: Accidental hemorrhage with couvelaire uterus

Fig-2: Placenta acreta with post partum hemorrhage

The incidence of peripartum hysterectomy is 4.1 cases per 10,000 births. Maternal mortality is 0.6% [10]. Previous cesarean delivery, maternal age over 35 years, parity of three or greater, previous manual placental removal, previous myomectomy and twin pregnancy were all risk factors for peripartum hysterectomy. The risk associated with previous cesarean delivery was higher with increasing number first cesarean delivery in the current pregnancy were also at increased risk. Earlier studies [11] revealed incidence of 0.04 %. Prior cesarean delivery was present in 88 % of the patients; a majority of the patients were grand multiparous, Para $\geq$ 6 (65 %). The incidence of hysterectomy after cesarean delivery was much higher than after vaginal delivery (0.3 vs. 0.01 %). Common indications included placenta accreta (65 %), uterine atony (27 %), and uterine rupture (8 %)

Post-operatively, 25 patients (38 %) developed DIC, 32 (48.5 %) had febrile illnesses, and 22 (33 %) experienced injury to the urinary tract. The maternal mortality in other study was 4.5 % [12]. In another study [13] there were 18 cases of emergency hysterectomy (14 caesarean hysterectomy and four postpartum hysterectomy, after vaginal delivery), giving a rate of 0.36/1,000 deliveries. Overall, the most common indication for hysterectomy was placenta accreta (28%) and uterine atony (28%). Although there was no maternal death, intra- and postoperative complications were prevalent including cardiac arrest, disseminated intravascular coagulopathy, pulmonary edema, septicemia, and bladder injury [14]. Placenta accreta is becoming a leading cause of emergency postpartum hysterectomy [15]. Although hysterectomy is a life saving operation, it is associated with high maternal morbidity.

In the present study we did not have any maternal mortality. 20 (76.92%) were antenatal unbooked .24 cases (92.30%) belonged to age group of 26-35 years. 22cases (84.61%) belonged to Para 3 and 4. 14 cases (53.84%) required emergency obstetric hysterectomy to control uterine bleeding. cases (23.07%) were due to misuse of oxytocics and 1 case (7.70%) was due to sepsis. it has been observed in the present study that atonic post partum hemorrhage requires to be controlled in time. Multiparity big baby placenta praevia placenta acreta delayed and obstructed labor malnourished anemic compromised patient are the contributory factors. Uterine bleeding after MTP due to trauma to uterus are other factors. One interesting case of cervical ectopic pregnancy also required hysterectomy to control bleeding. Prevention lies in proper control of post caesarean normal delivery trials and mis use of oxytocics. A prompt and early decision to perform emergency hysterectomy can save life.

With the advent of prostaglandins, potent oxytocics, potent clotting factors, blood and blood products, newer antibiotics and newer conservative interventions requirement of emergency hysterectomy has markedly reduced, but this still remains life saving tool. Decision should not be delayed and will definitely reduce maternal mortality and morbidity. Regular ante natal care is the basic tools in identifying risk factors and prompt treatment.

Assessment of Hormonal and Reproductive Factors Associated with Low Back Pain in Reproductive Female in A Tertiary Care Teaching Hospital

Jini Gupta[1], Vikas Gupta[2*]

[1]Assistant Professor, Department of Obstetrics and Gynaecology, [2]Associate Professor, Dept. of General Surgery, Ananta Institute of Medical Sciences and Research Centre, Rajsamand

ABSTRACT

Background: *Low back pain related disability and work absence accounts for high economical costs in modern society. A prevalence of 28-80% has been found with increase of prevalence with age and female preponderance.*

Methods: *The present study was conducted on 150 non pregnant women complaining of low back pain attending Department of Obstetrics and Gynaecology, Pacific Institute of Medical Sciences during the period of one year. A brief questionnaire was used to screen, among the respondents, the occurrence of low back pain in the past year.*

Results: *Low back pain was associated with high BMI, high waist circumference, more number of children, irregular and prolonged duration of menstruation, young maternal age at first birth and with history of abortion.*

Conclusion: *The present study conclude that Hormonal and reproductive factors are associated with low back pain.*

Keywords: *Hormonal factors, Reproductive factors, Reproductive female*

INTRODUCTION

Low back pain is defined as pain and discomfort, localized below the costal margin and above the inferior gluteal folds, with or without referred leg pain. Chronic low back pain is defined as low back pain persisting for at least 12 weeks, unless specified otherwise. A simplified and practical classification, which has gained international acceptance, is to divide low back pain into three categories-the so called "diagnostic triage"[1] : 1. Specific spinal pathology 2. Nerve root pain pain/radicular pain 3. Non-specific low back pain Low back pain is common disorder, affecting around one-third of UK adult population each year. About 20% of people of low back pain (that is 1 in 15 of population) will consult their GP about it. The presence of low back pain during pregnancy is widely reported.[2-5] One systematic review identified 56 population prevalence studies of low back pain (Walker 2000). Thirty studies were of acceptable quality. Point prevalence of low back pain ranged from 12-33%. The two reviews on low back pain in school children and adolescents reported a prevalence approaching that reported for adults.[6,7] Low back pain fluctuates over time with frequent recurrences and exacerbations.[8] The first review reported that, after a first episode of low back pain, the proportion of patient who still experienced pain after 12 months was on average 62% (range 42-75%), the percentage who experienced relapses of pain was 60% (range 44-78%) and the percentage who had relapses of work absence was 33% (range 26-37%).[9] Factors which are associated with low back pain are young age at menarche, irregular or prolonged menstruation, past pregnancy, young maternal age at first birth, and duration of oral contraceptive use, hysterectomy and use of estrogens during

menopause.[10] Other factors associated with low back pain are previous miscarriage, presence of endometriosis, clinically suspected pelvic inflammatory disease, caesarean section scar, pelvic adhesions, sexual abuse, anxiety, and depression. Back pain is a commonly described symptom of the premenstrual syndrome.[11] Therefore this study was conducted to assess the hormonal and reproductive factors associated with low back pain in reproductive female.

METHODS

The present study was conducted on 550 non pregnant women complaining of low back pain attending Department of Obstetrics and Gynaecology, Pacific Institute of Medical Sciences during the period of one year. The subjects were randomly allocated and found 150 patients suffering from low back pain.

Inclusion criterion

1. Women attending outpatient department of obstetrics and Gynecology in UISEMH.
2. All females of age 20-45 yrs. of any religion and socioeconomic status.

Exclusion criterion

1. Women who have attained physiological menopause.
2. Subjects who were not able to communicate because of dialect or hearing problems.

Study protocol

A brief questionnaire was used to screen, among the respondents, the occurrence of low back pain in the past year. The questions included occurrence of low back pain, demographic factors and reproductive health history. Low back pain was identified among subjects who have back pain lasting for more than a day in an area between the lower coastal margin and the gluteal folds with or without radiation into leg to below the knees during the past one year. The anthropometric measurements included measures of body height (cm) and weight (kg) using standard measurement equipment's. Waist and hip circumference (cm) were assessed using a measuring tape while the subject was standing. Other factors evaluated were occupation, education and smoking. Sociodemographic profile, menstrual and obstetric history were noted and also the use of oral contraceptives.

RESULTS

Out of 550 subjects, 150 were patients of low back pain. Majority of patients, 58.8% were in age range of 45-50 years and only 10.5% in 25-30 years of age group. Out of 150, 55.6% belongs to socioeconomic Class 1 and 2. Only 35 patients had education of university and above. 28% (42/150) were Labourers and rest 72% had some other occupation. 58.66% (88/150) had weight below median (60 kg) and only 41.34% had weight above median.

Patients with BMI (>25kg/m^2) were 52.5% and 47.5% had BMI below 25 kg/m^2. 111 out of 150 had waist circumference of <80 cm and 92 (61.33%) had more than 80 cm. Their waist-hip ratio is <0.8 in 82 patients (54.66%).

Majority of patients had more than two parity (62.6%). Patients with vaginal and caesarean delivery were 62 (41.33%) and 88 (58.66%) respectively. 84 patients out of 150 had irregular menstruation. Majority of them (67.4%) had duration of flow of more than 8 days. 98 patients had premenstrual syndrome. 65.5% patients had undergone sterilization and 42.66% (64/150) were using oral contraceptives. 95 patients had history of abortion and 34.5% patients had pelvic organ prolapse.

DISCUSSION

The study showed that hormonal and reproductive factors like irregular or prolonged menstrual cycle were associated with low back pain. Estrogen related factors like past pregnancy, young maternal age at first birth, oral contraceptive use were specifically associated with low back pain. Young age at menarche was also associated with low back pain. One theory is that increased estrogen results in increased laxity of joints and ligaments. This increased laxity then leads to LBP. Like results from other studies, association was found between the number of children and low back pain.[12,13] A previous population-based survey found a linear association between the number of live births and chronic low back pain. Results from our study suggest that there is association between the parity and low back pain. In a population-based survey among women younger age at first pregnancy was also associated with a high prevalence of ever having low back pain.[13] Our study shows association between younger age at first pregnancy and low back pain. In 1995, Brynhildsen et al reported that many health professionals believe that there is an association between oral contraceptive uses with low back pain, despite the lack of scientific evidence.[14] Unlike this study our study showed no association between oral contraceptive use and LBP. We found menarche at young age (<11 YEARS) to be not associated with LBP. Although LBP is positively correlated with menstruation in women and back pain is a common symptom of the premenstrual syndrome, there are only few studies describing the association between the menstrual pattern and musculoskeletal disorders.[12,15]

CONCLUSION

Hormonal and reproductive factors like an irregular or prolonged menstrual cycle are associated with low back pain, suggesting that these factors are associated with musculoskeletal pain in general. Factors related to increased estrogen levels like past pregnancy, young maternal age at first birth, duration of oral contraceptive use may specifically increase the risk of low back pain. More research is needed to examine these associations and unravel biologic explanations.

Dear Dr. Vikas Gupta

Following the review of your manuscript with above mentioned Manuscript ID, submitted on 03.01.2021, Editorial Board is pleased to inform you that your manuscript is accepted for publication as Original Research Article under the section of Obstetrics & Gynaecology in the forthcoming issue of International Archives of BioMedical and Clinical Research. Your article has been sent for further processing and editing.

We thank you for submitting your valuable work to International Archives of BioMedical and Clinical Research and hope in future you would keep on sending high quality manuscripts to our journal.

With Best Regards,

Farhan Ahmad Khan

Editor-in-Chief

Recurrence Rate in Primary Pterygium Managed by Surgical Excision of Pterygium with Application of Mitomycin-C over Bare Sclera and Free Conjunctival Autografting

Devendra Sharma

Assistant Professor, Department of Ophthalmology, Ananta medical college and research center, Rajsamand (Raj)

ABSTRACT

Background: *To study recurrence rate in 50 cases of primary pterygium managed by surgical excision of pterygium along with application of mitomycin-C 0.02% over bare sclera for 2 minutes and ipsilateral free conjunctival autografting.* ***Methods:*** *This prospective observational study was carried out on 50 patients of primary pterygium operated between 15.03.2016—10.08.2016. Pterygium excision was done, 0.02% mitomycin-C was applied over bare sclera for 2 minutes and ipsilateral free conjunctival autografting was done using sutures. Patients were followed up for a mean period of 13.27 months for recurrence.* ***Results:*** *55 eyes of 50 patients were operated by above technique by a single surgeon1. Three (3) patients were lost in follow up. In an average follow-up time of 13.27 months, recurrence was found in only 1 case (1.92%). No serious side effects were observed in this study.* ***Conclusions:*** *Primary Pterygium managed by excision of pterygium followed by intraoperative mitomycin-C application and conjunctival autografting is an easy, reproducible and cost effective method which helps in reducing recurrence with minimal complications.*

Key words: *Pterygium, mitomycin-C, conjunctival autografting, recurrence rate.*

INTRODUCTION

Pterygium is a condition in which subconjunctival tissue proliferates as a vascularized granulation tissue to invade and destroy superficial layers of cornea as a triangular encroachment usually from nasal side. It has an apex (head), neck and body and contains abnormal, elastotic fibrous tissue. It may present as atrophic, flat & slow growing having less chances of recurrence or it may present as rapidly progressing fleshy growth with high recurrence rates after excision.

Ordinarily it is asymptomatic. Symptoms may arise due to repeated inflammation, infection and cosmetic disfigurement. It may diminish vision due to induced astigmatism and encroachment into pupillary area. It may cause diplopia, interfere with contact lens wear and very rarely it may undergo neoplastic changes. Etiology is not clearly understood. Presence of numerous fibroblasts and elastodysplasia implicate actinic damage leading to abnormal tissue formation.

Prophylactic treatment such as avoiding long exposure to sunlight, dry & dusty environment and using UV protected glasses may help. Medical therapy is usually symptomatic in the form of decongestant, NSAID & Lubricant eye drops. Surgery is the definitive treatment.

Excision of Pterygium by bare sclera technique alone has unacceptably high recurrence rates so different modalities of

Quick Response code

treatment have been tried along with it. Closure Techniques have been tried using grafts (free conjunctival, Limbal-conjunctival, mucosal and amniotic membrane) with or without help of serum, glue or sutures. Antimetabolites such as Thio-tepa, Mitomycin-C & Daunorubicin and anti-VEGF drugs like bevacizumab & ranicizumab have also been tried. Keratoplasty may be used in special cases.

METHODS

The present study was conducted on 50 (fifty) patients with primary pterygium attending the eye-OPD of Ananta hospital from 25.05.2016—10.08.2016. They were managed by surgical excision of pterygium with intraoperative mitomycin-C 0.02% application for 2 minutes and free conjunctival autografting from same eye. All operations were performed by single surgeon so that surgeon's factor did not influence the outcome. Selection criteria were patients who had primary pterygium and were willing to undergo the surgery after understanding the nature of the treatment, its potential complications and prognosis.

Exclusion criteria were recurrent pterygium, associated ocular diseases and patients who did not turn-up in follow up. A written consent was taken from all the patients before the procedure. All pterygia were divided into 4 Grades as suggested by Youngson RM in 1972. Lab tests done were FBS, Hb, BT, CT, HIV, HBsAg and HCV

Surgical Technique

All patients were operated under peribulbar block. Pterygium head was shaved off the cornea trying for a minimal & smooth keratectomy and was excised midway between limbus and canthus. Freshly prepared Mitomycin 0.02% was applied over bare sclera for 2 minutes after which thorough irrigation was done using normal saline. Slightly larger sized superotemporal conjunctival flap was dissected as thin as possible without button holing. After excision, the graft was correctly oriented over bare sclera and sutured with interrupted 8-0 silk sutures. Post-operative Lubricant eye drops & Moxifloxacin eye drops QID was used. After 2 days moxifloxacin was switched over to Tobramycin-Dexamethasone eye drops QID. Patient was reviewed weekly for a month, fortnightly for 2 months and monthly thereafter for at least 6 months. Recurrence was defined as fibrovascular tissue crossing over limbus on to clear cornea in the area of previous pterygium excision.

RESULTS

Seventy patients (71) patients of pterygium attended eye OPD from 25.05.2016—10.08.2016.

As per selection criteria 50 patients (34 male and 16 female) of primary pterygia were selected and 21 were excluded. Five patients were operated for bilateral pterygia and; so, a total of 55 pterygia were operated. Three (3) patients were lost in follow-up leaving behind 52 cases of pterygia for the study. Maximum no. of patients (37.87%) was in 31-40 yrs age group.

Presenting complaints were Irritation, watering & redness in 45 (90%), discomfort & itching in 36 (72%) and cosmetic disfigurement in 5 (10%) patients.

Pterygia were graded as suggested by Youngson[1] R.M. (1972) into four Groups I—IV

And subdivided into 'a' for small sized pterygium and 'b' for large fleshy pterygium.

Most patients were in III b group 21 (40.4%) with majority falling in II and III grades 45 (86.5%)

Mean duration of disease was 8.25 years (Range 2—20 yrs). Follow up time varied from 7—15 months (Mean 13.27 months)

Pterygium was nasal in all cases and bilateral in 12 cases. In patients having bilateral pterygia 5 patients opted for surgery in both eyes and 7 patients opted for surgery in only one eye having advanced pterygium. Ocular movements were normal and IOP was within normal range (10—20 mm of Hg) in all cases. Post-op subjective complaints were mild ocular pain in 34(68%), redness & discomfort in 33(66%) and foreign body sensation, epiphora & itching in 21(42%). Treatment was conservative and symptoms resolved in coming days.

Objective signs in early Post-op were haemorrhage/hematoma beneath the graft in 8(15.4%), serous exudates beneath the graft in 8(15.4%), cut through one/two sutures in graft in 3(5.7%), encroachment of graft over cornea in 2(3.8%) and Superficial punctuate epitheliopathy of cornea in 2(3.8%). All were managed conservatively and they resolved in coming days. Superotemporal donor bed of conjunctiva healed uneventfully.

A late Post-op complication was graft retraction in 2(3.8%) cases which healed normally within 3—4 weeks. Recurrence was found in only 1(1.92%) case after 45 days of surgery in a 21-year-old patient who had bilateral fleshy pteryiga (Grade IV 'b') pre-operatively.

Anterior segment, ocular movements & IOP showed no significant changes when compared to pre-op findings.

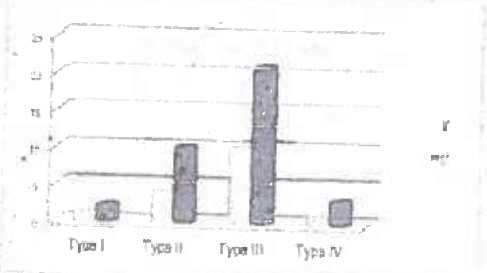

Figure 1. GRADING OF 52 PTERYGIA.

Grading of 52 Pterygia			
TYPE	PTERYGIUM INVADING	'a'	'b'
I	<1.5 mm cornea	1	2
II	< half the radius of cornea	4	10
III	>half the radius of cornea	10	21
IV	almost center of cornea	1	3

DISCUSSION

One of the most important aim in management of pterygium is to prevent its recurrence after removal. Different modalities of treatment have been tried to prevent recurrence with varying success. We tried to combine two well documented modalities of treatment for management of pterygium.

In our study 55 primary pterygia (in 50 patients) were operated by surgical excision of pterygium, intra-operative application of 0.02% mitomycin-C over bare sclera for 2 minutes and ipsilateral free conjunctival autografting. Out of these 55 cases, 3 were lost in follow-up leaving 52 cases for the study. All the operations were performed by single surgeon[11], so that the surgeon's factor did not influence the surgical outcome in terms of complications and recurrence. Maximum number of pterygia was in II and III grades 45 (86.5%).

Duration of disease in our study varied from 2—20 yrs (mean 8.25 yrs). Follow-up time varied from 7—15 months (mean 13.27 months).

Post-operative complaints were mild and were successfully managed conservatively.

Post-operative complications were trivial and got resolved by conservative treatment.

Recurrence was found in 1 case (1.92%) in our study after 45 days of surgery in a 21 yr old person who had bilaterally large fleshy pterygia (grade IV 'b') preoperatively.

Hirst LW (1994)[12] found that 50% recurrences occur within 120 days of surgery and 97% by 12 months. Recurrence could be contributed to the fact that the disease activity is more in young age groups and the fleshiness of pterygium which is a significant risk factor in recurrence as was found by Tan et al[13] in 1999.

When only mitomycin-C was used, Recurrence rates observed was 4% by Frucht Pery[14] (1994), 25% by Levartovsky[15] (1998) and 7.9% by Cheng[16] HC (2001).

When only Conjuctival autografting was performed, Recurrence rate observed by Kenyon[17] (1985) was 5.3%, Riordan [18] Eva P (1993) was 7.64% and Ti se[9] et al (2000) was 20.8%.

Wong[10] VA & Law FC(1999) found 18% recurrence in conjunctival autograft cases and 9% recurrence in patients treated with mitomycin-C + conjunctival autograft.

Serious complications reported by Rubinfeld[111] (1992) such as corneal ulceration, scleral thinning, cataract formation, uveitis, secondary galucoma and plaque formation were not found in our study.

The combined use of these two modalities (mitomycin-C & conjunctival autografting) has not been studied extensively in the management of pterygium. We used mitomycin-C in low dose and for short duration, as recommended in previous studies, to minimize complications.

In our study combined use of these two modalities has been found to be synergistic to each other; thereby increasing the success rate and decreasing the complications.

CONCLUSION

In the present study 52 primary pterygia were managed by surgical excision of pterygium, application of 0.02% mitomycin-C over bare sclera for 2 minutes followed by ipsilateral free conjunctival autografting. In an average follow-up time of 13.27 months the recurrence was found in only 1 case (1.92%); which is much lower as compared to bare sclera technique alone or when combined with either mitomycin-C or with conjunctival autografting. Complications encountered in present study trivial in nature & were easily managed. No serious side effects were observed in this study. In the view of low recurrence rate with minimal and mild complications this cost-effective modality of pterygium management seems to be a very good choice as a first line of treatment for primary pterygium.

ABSTRACT

Objective: To assess the relationship between allergic rhinitis and allergic conjunctivitis and to assess the role of Intranasal corticosteroid in the management of Allergic rhinoconjunctivitis.

Material and methods: The study was done in Ananta Institute of medical Sciences, Rajsamand, Rajasthan from February 2016 to October 2017. A total of 100 patients with the diagnosis of allergic rhinitis or allergic conjunctivitis attended ENT or Ophthalmology outpatient department were included in our study. Type I allergy was tested by a specific IgE antibody test in the blood. iTNSS (instantaneous total nasal symptom score), iTOSS (instantaneous total ocular symptom score), rTNSS(reflective total nasal symptom score) and rTOSS (reflective total ocular symptom score) were noted before as well as after 1 week treatment with intranasal steroid spray Fluticasone Furoate(FF).

Results: A total of 100 patients were included in our study out of which 47 were male and 53 were female. Age of the patients ranges from 20 to 60 years with the mean age of 34.8 years.

79% cases included in present study were having symptoms of rhinoconjunctivitis, 13% cases were having only rhinitis symptoms and rest 8% were having only conjunctivitis symptoms.

The mean pre treatment iTNSS and iTOSS scores were 4.45±2.70 and 2.35±1.45 respectively, similarly, the mean post treatment iNSS and iTOSS were 2.36±1.74 and 1.16±1.43 respectively.

Conclusion: eye symptoms frequently occur in allergic rhinitis and the mechanism behind this can be explained by a neural mechanism i.e. nasal-ocular reflex. Intranasal steroid like Fluticasone Furoate with high topical potency and low potential for systemic effects is a good candidate for rhinitis treatment as well to manage ocular symptoms.

KEYWORDS

Allergic rhinoconjunctivitis, intranasal steroid, Fluticasone Furoate

Introduction:

Rhinitis is defined as an inflammation of nasal mucosa and is characterized by itching of eyes/ears/nose/palate, sneezing, nasal congestion, clear rhinorrhoea, post nasal drip, facial pain, morning cough, headache, red watery eyes and/ or sleep disturbances.

When symptoms of rhinitis are triggered by an allergen, the resulting condition is referred to as allergic rhinitis. Allergic rhinitis may be seasonal, perennial, or may occur sporadically after specific exposures.

Eye symptoms frequently occur in patients with allergic rhinitis and are among the most bothersome symptoms so it is better to use term allergic rhinoconjunctivitis (AR) instead of using allergic rhinitis or allergic conjunctivitis separately for such symptoms.

In addition to the typical nasal and eye symptoms, AR leads to a significant impairment of the quality of life of its sufferers when measured by both generic and specific quality of life instruments [1, 2]. Also associated with the disease are fatigue and daytime sleepiness,(1,3) reduced work productivity,(4–6) impaired cognitive functioning,(7, 8) reduced learning abilities,(9) and impaired sleep (10).

The pathophysiological mechanisms of the eye symptoms in allergic rhinoconjunctivitis include a direct effect on the eye by deposited allergen and indirect effects related to the deposition of allergen in the nasal mucosa. One of these proposed mechanisms is the existence of a nasal-ocular reflex whereby the nasal allergic reaction leads to an afferent reflex response, the efferent limb of which results in eye symptoms. Among the treatments available for allergic rhinitis, intranasal steroids are most efficacious for nasal symptoms and have also shown sizeable efficacy related to eye symptoms. It is helpful for diagnosing the allergic conjunctivitis and rhinitis to have a clearer understanding of the relationship between the two diseases. So the objective of the present study is to assess the relationship between allergic rhinitis and allergic conjunctivitis and to assess the role of intranasal corticosteroid in the management of Allergic rhinoconjunctivitis.

Material and Method:

The study was done in our tertiary care hospital from February 2016 to October 2017. A total of 100 patients with the diagnosis of allergic rhinitis or allergic conjunctivitis attended ENT or Ophthalmology outpatient department were included in our study.

All the patients were thoroughly examined, clinical history was taken and routine laboratory investigations were performed to rule out any co morbid disorders.

Allergic conjunctivitis was diagnosed as if the patient had characteristic symptoms and signs based on criteria set out by Buckley in 1998(11), and allergic rhinitis was diagnosed according to the criteria set out by allergic rhinitis impact on asthma (ARIA) in 2001(12).

Type I allergy was tested by a specific IgE antibody test in the blood. Eosinophils were detected in superficial conjunctival scrapings of the superior tarsal conjunctiva, and mucosal surface scrapings of middle meatus was taken in some severe cases (with permission of patient for the examination).

iTNSS (instantaneous total nasal symptom score), iTOSS (instantaneous total ocular symptom score), rTNSS(reflective total nasal symptom score) and rTOSS (reflective total ocular symptom score) were noted of all the patients. Fluticasone Furoate nasal spray was then advised to all the patients to administer two puffs twice a day. Post treatment scores were then calculated after one week of treatment with intranasal steroid.

Pre treatment and post treatment scores were compared to know about the efficacy of intranasal steroids in the treatment of allergic rhinoconjunctivitis.

Results:

A total of 100 patients were included in our study out of which 47 were male and 53 were female.

Age of the patients ranges from 20 to 60 years with the mean age of 34.8 years.

79% cases included in present study were having symptoms of

patients included, 100 patients were having only rhinitis symptoms and 96 were having only conjunctivitis symptoms.

The mean pre treatment rTNSS and rTOSS scores were 4.45±2.70 and 2.48±1.56 respectively. Similarly the mean post treatment rNSS and rTOSS were 2.36±1.74 and 1.26±1.43 respectively (Table. 1). The results showed significant reduction in nasal and ocular symptom after 1 week of treatment with intranasal steroid (p value < 0.05).

Table.1 The mean pre-treatment and post-treatment total nasal symptom score and total ocular symptom score.

Scores	Pre-treatment score	Post-treatment score
rTNSS	4.25±2.45	2.45±1.80
rTOSS*	2.48±1.56	1.26±1.30
iTNSS	4.45±2.70	2.36±1.74
iTOSS	2.35±1.45	1.16±1.43

Boldface type indicates significance at a value of $p < 0.05$.
rTNSS : reflective total nasal symptom score; iTNSS: instantaneous total nasal symptom score;
rTOSS: reflective total ocular symptom score; iTOSS: instantaneous total ocular symptom score.

Discussion:

Allergic rhinoconjunctivitis is often used interchangeably with allergic rhinitis because ocular symptoms are usually present in allergic rhinitis. Studies have found a high incidence of watery/itchy eyes in allergic rhinoconjunctivitis (61–81%) (13, 14). Similarly in present study, 79% patients were having eye symptoms in allergic rhinoconjunctivitis.

There have been so many evidences and studies that support intra nasal steroids as a single-modality treatment for both nasal and ocular symptoms of allergic rhinoconjunctivitis (15, 16).

Consistent with previous studies, present study also indicated significant reduction in nasal and ocular symptoms after using fluticasone furoate nasal spray for 1 week.

The present study suggested that the beneficial effect of intra nasal steroids in reducing eye symptoms in allergic rhinoconjunctivitis is in support of existence of a nasal-ocular reflex.

However, several other mechanisms of this beneficial action have been proposed. By inhibiting local nasal inflammation i.e., production of cytokines and infiltration of inflammatory cells—intranasal steroids may have indirect systemic effects that reduce inflammation in other tissues, including the eyes (17).

Another possible explanation is that intranasal steroids may reduce inflammation of the nasolacrimal duct, thereby improving nasolacrimal drainage and reducing conjunctival exposure to allergens and inflammatory mediators (18). This hypothesis is undermined by the finding that nasolacrimal duct blockage does not increase the response to ocular antigen challenge, and by the Jones test, which shows continued patency of the nasolacrimal duct during allergic reactions in the nose (19).

It has also been suggested that intranasal steroids may travel through the nasolacrimal duct and thereby have direct anti- inflammatory effects on the conjunctiva. The lack of steroid related ocular side effects, such as glaucoma and cataract, indicates that movement through the nasolacrimal duct is not a viable mechanism for the ocular effects of intranasal steroids.

Although corticosteroids have potent systemic anti-inflammatory effects, systemic absorption of these agents after topical administration is below the level that would be expected to produce systemic effects, especially after the drug has been diluted by the blood before it can be delivered to the eye. The systemic bioavailability of fluticasone furoate after intranasal administration is less than 0.5%. Therefore, it is unlikely that intranasal steroids act systemically to relieve ocular symptoms, especially those caused within minutes of antigen challenge (18, 20).

Although our study investigated the effect of one of the available intranasal steroids, Fluticasone Furoate Nasal Spray, it is likely that the observed beneficial effect on eye symptoms in patients with allergic rhinoconjunctivitis extends to other agents also within this class.

This is evidenced by several clinical studies using other intranasal steroids that demonstrate similar beneficial effects on eye symptoms (21,22).

Conclusion:

Eye symptoms (itching, watery eyes, and redness) are an important part of the overall burden of allergic rhinoconjunctivitis and are associated with significant bother to allergy sufferers. These effects probably occur by several mechanisms, the most obvious of which, is the direct deposition of allergen in the conjunctiva and the generation of an ocular inflammatory response. Another mechanism that might contribute to the genesis of ocular symptoms in allergic individuals is a neural reflex generated in the nose upon exposure to allergen that results in an amplification of the allergic response to the other nostril and also to both eyes i.e. naso-nasal and nasal-ocular reflex. This mechanism might explain the efficacy of intranasally administered steroids in controlling ocular symptoms.

Fluticasone Furoate nasal spray is a new topical corticosteroid, with enhanced-affinity and a unique side-actuated delivery device, which is effective in improving nasal symptoms of AR. Significant improvement in ocular symptoms and in quality of life was also demonstrated. Its low oral bioavailability and high plasma protein binding minimize systemic adverse effects. A potentially prolonged nasal retention time may further enhance the efficacy of FF, which may allow for a once-daily dosing regimen in adults, adolescents, and children.

FF with high topical potency and low potential for systemic effects is a good candidate for rhinitis treatment. As expected for all new drugs, long-term safety and efficacy studies are required, which can establish the potential modification in allergic rhinoconjunctivitis management.

Objective: The present study was conducted to assess the efficacy and safety of bilastine 20 mg and compare the results with that of levocetirizine 5 mg in the treatment of allergic rhinoconjunctivitis. **Material and Methods:** It was a prospective study conducted in the Department of Ophthalmology and Department of Otorhinolaryngology at a tertiary institute of southern Rajasthan, India during the period of 6 months from September 2019 to February 2020. 100 patients of chronic allergic rhinoconjunctivitis were included in the study, of which 50 were treated with Bilastine 20 mg, and the rest 50 patients were treated with levocetirizine 5 mg. The primary assessment was done by calculating the total symptom score (TSS) before and after the 7th and 14th post-treatment day. **Results:** The age of the patients ranges from 10 years to 65 years with a mean age of 32±5.2 years. The primary efficacy parameter for assessment was a reduction in total symptom score (TSS). Both bilastine 20 mg and levocetirizine 5 mg significantly reduced the TSS on the 7th and 14th post-treatment days (p-value< 0.001). There was no significant difference between TSS of bilastine and levocetirizine after 7 days (p-value= 0.41) and after 14 days treatment (p-value= 0.68). Adverse events were reported by 10% of patients in the bilastine group and by 38% of patients in the levocetirizine group. **Conclusion:** Bilastine is a selective H1 antihistamine with good efficacy and excellent safety profile and it is highly recommended to use it as a first-line treatment for allergic rhinoconjunctivitis.

Introduction

Allergic rhinoconjunctivitis is a common problem worldwide and its incidences are increasing day by day [1]. Data suggest that approximately 10-40% of the global population is affected by allergic rhinoconjunctivitis [2-5]. Allergic diseases impose a negative impact on a patient's physical, social, and psychological functioning with an adverse effect on a person's work capacity and quality of life.

H1 antihistamines are used as first-line treatment to treat allergic rhinoconjunctivitis for a long time [6-8]. First-generation H1 antihistamines have many side effects including anticholinergic effects, sedation, and interaction with alcohol and other drugs. Second-generation H1 antihistamines are free of anticholinergic effects, cause no sedation, and do not interact with alcohol or other drugs and thus, are used as first-line treatment for allergic diseases.

Bilastine is a newer generation, selective H1 antihistamine of the piperidine family. It was first approved by the European society of physicians in 2010 for symptomatic treatment in allergic rhinoconjunctivitis (seasonal or perennial) and now it is available worldwide [9].

Bilastine displays only limited penetration across the blood-brain barrier so does not cause sedation or somnolence and does not alter the cognitive performance of the patient, also does not potentiate the effects of alcohol. It does not exhibit any anticholinergic or cardiotoxic effect. So bilastine is comparatively safe and well-tolerated H1-antihistamine for the treatment of allergic rhinoconjunctivitis.

The present study has been performed to compare the efficacy and safety of bilastine 20 mg with levocetirizine 5 mg for the treatment of allergic rhinoconjunctivitis.

Material and Methods

It was a prospective study conducted in the Department of Ophthalmology and Department of Otorhinolaryngology at Ananta Institute of Medical Sciences, Rajsamand during the period of 6 months from September 2019 to February 2020.

Study design: Prospective, randomized, double-blind study.

Study population: 100 patients Who attended ENT or Ophthalmology outdoor with the clinical diagnosis of allergic rhinitis or allergic conjunctivitis during the study period, were included in the study. Out of 100 patients, 50 were treated with Bilastine 20 mg, and the rest 50 patients were treated with levocetirizine 5 mg. Both the medicines were advised to take once a day orally for 2 weeks.

Inclusion criteria:

All the patients who attended ENT or ophthalmology outdoor with the clinical diagnosis of allergic rhinitis or allergic conjunctivitis during the study period were included in the study.

Exclusion criteria:

01. Non-allergic rhinitis
02. History of intake of any type of anti-allergic medication for the past 2 weeks
03. Patients are unable to complete the questionnaire or not willing to take part in the study.

Assessment:

Primary outcome: All the study participants were advised to record their total symptom score (TSS) daily for 2 weeks (14 days). TSS was calculated daily as the sum of four nasal symptoms (sneezing, itching, rhinorrhea, and congestion) and three non-nasal symptoms (ocular symptoms- tearing, itching, and redness) symptom score (NSS and NNSS respectively).

Secondary outcome: All the patients in both groups were asked to report any adverse events suffered during and after the treatment.

Statistical analysis

Data analysis was performed using Statistical Package for Social Sciences (SPSS) software, version 19.0. Data of both the groups were compared and analyzed by Chi-square test or Student's t-test.

Results

100 patients with a clinical diagnosis of allergic rhinoconjunctivitis were included in the study and were randomized to double-blind treatment with bilastine 20mg and levocetirizine 5mg once daily for 2 weeks.

The age of the patients ranges from 10 years to 65 years with the mean age of 32±5.2 years.

The primary efficacy parameter for assessment was a reduction in total symptom score (TSS). Both bilastine 20 mg and levocetirizine 5 mg significantly reduced the TSS on the 7th and 14th post-treatment days (p-value< 0.001). There was no significant difference between TSS of bilastine and levocetirizine after 7 days (p-value= 0.41) and after 14 days treatment (p-value= 0.68). this shows that the symptom-relieving effect of both bilastine and levocetirizine are comparable (Table 1).

Table-1. Effect of treatment on total symptom score (TSS) in bilastine and levocetirizine groups.

Total symptom score	Bilastine group (mean±SD)	Levocetirizine group (mean±SD)	P-value
Pre-treatment score	7.47±2.10	7.41±2.06	0.88
Post-treatment score (on 7th day)	3.66±1.80 (0.0001*)	3.97±1.99 (0.0001*)	0.41
Post-treatment score (on 14th day)	2.79±1.05 (0.0001**)	2.88±1.14 (0.0001**)	0.68

*P-value between pre-treatment and 7th post-treatment day score.

**P-value between pre-treatment and 14th post-treatment day score.

Adverse events were reported by 10% of patients in the bilastine group and by 38% of patients in the levocetirizine group. The most common adverse event was somnolence followed by fatigue and dry mouth. All the adverse events were mild in severity (Table 2).

Table-2. Adverse events reported during 2 weeks of treatment with bilastine and levocetirizine.

Adverse events	Bilastine group (n=50)	Levocetirizine group (n=50)
Headache	1	2
Somnolence	1	11
Fatigue	3	3
Dry mouth	0	3
Total	5 (10%)	19 (38%)

Discussion

Allergic rhinoconjunctivitis affects people of all ages and harms a person's work efficiency and quality of life [10-17]. Second generation oral H1 antihistamines such as Bilastine, are prescribed as a first-line medication to treat allergic rhinoconjunctivitis [7,8,18,19].

Bilastine is a potent and highly selective oral H1-antihistamine that meets all the criteria of ARIA guidelines for medications to treat allergic rhinitis. The present study was specifically designed to assess the efficacy and safety profile of bilastine for the treatment of chronic allergic rhinosinusitis and to compare these with that of levocetirizine.

In the present study, both bilastine 20 mg and levocetirizine 5 mg significantly reduced the TSS on the 7th and 14th post-treatment days (p-value< 0.001). Pre-treatment TSS in the bilastine group was 7.47±2.10 which was reduced to 3.66±1.80 on the 7th post-treatment day and further reduced to 2.79±1.05 on the 14th post-treatment day. Similarly, pre-treatment TSS in the levocetirizine group was 7.41±2.06 which was reduced to 3.97±1.99 on the 7th post-treatment day and further reduced to 2.88±1.14 on the 14th post-treatment day. There was no significant difference between TSS of bilastine and levocetirizine after 7 days (p-value= 0.41) and after 14 days treatment (p-value= 0.68). Adverse events were reported by 10% of patients in the bilastine group and by 38% of patients in the levocetirizine group. The most common adverse event was somnolence followed by fatigue and dry mouth. All the adverse events were mild in severity (Table 2).

Our findings of the efficacy of bilastine are following the preliminary findings of Kuna P et al who performed a similar study with 683 patients in 2009. They compared the effect of bilastine with cetirizine and placebo. The mean TSS on the 14th day was reduced in the bilastine and cetirizine group to a similar and significantly greater extent, compared with the placebo group (p-value<0.001). Also when the comparison is done for adverse events, significantly fewer patients in the bilastine group experience somnolence (p value<0.001) and fatigue (p-value = 0.02) than patients in the cetirizine group [20].

Another study was performed in the past by Bachert C et al with a comparison of bilastine 20 mg, Desloratadine 5 mg, and placebo. A total of 721 patients of rhinoconjunctivitis were included in the study. TSS was significantly reduced in the bilastine group with the placebo group (p value< 0.001). The safety profile of bilastine and desloratadine was comparable to placebo [21].

Similar studies were carried out by Davila et al. and Bartra et al in 2011 and the results were following the present study.

They analyzed the data about the effect of bilastine upon nasal obstruction and ocular symptoms in 2-4 weeks duration clinical trial. Davila found a significant reduction in nasal obstruction symptom score after two weeks of treatment of bilastine 20 mg or cetirizine 10 mg or desloratadine 5 mg when compared to placebo. (p-value < 0.001). similarly, Bartra et al. found bilastine more effective in relieving ocular symptoms than placebo and as effective as other active comparators [22,23].

Zuberbier T et al. performed a placebo-controlled comparative study of the safety and efficacy of bilastine 20 mg and levocetirizine 5 mg for the treatment of chronic urticaria. They found the efficacy of bilastine 20 mg was comparable to levocetirizine 5 mg in the treatment of chronic urticaria. The differences in overall adverse events were not significant among the treatment groups [24].

In summary, the present study confirms and support the literature that bilastine 20 mg is a novel, safe, and effective treatment option for patients with chronic allergic rhinosinusitis

Limitations

01. Small sample size

02. The study was conducted over a short period

Conclusion

Bilastine is a new generation, non-sedating H1 antihistamine of the piperidine family. The present study was a comparative analysis of efficacy and safety between bilastine 20 mg and levocetirizine 5 mg for the treatment of chronic allergic rhinoconjunctivitis. The study suggests that a therapeutic dose of 20 mg bilastine meets current EAACI/ARIA criteria for medications used in the treatment of allergic rhinoconjunctivitis. Bilastine has similar efficacy to another second-generation H1 antihistamine with a more favorable safety profile so it can be used as a first-line treatment of allergic rhinoconjunctivitis.

What does the existing study add to the existing knowledge?

Many antihistamines are used as first-line treatment for allergic rhinoconjunctivitis but older generation antihistamines have some safety issues so newer medications are used nowadays.

Bilastine is a newer generation non-sedative H1 antihistamine with comparable efficacy and a better safety profile.

The present study adds various benefits of bilastine over other antihistamines and supports the fact that bilastine can be used as a first-line treatment for allergic rhinoconjunctivitis.

Abstract

Background: Dry eye disease is a common disorder provoking changes in tear film and ocular surface. Untreated dry eye could cause ocular infections, corneal ulcer and blindness. Only a few drugs are authorized so far for the treatment of severe dry eye disease and the possibilities of evolution in this sector are immense.**Objectives:** Compare efficacy of carboxy methyl cellulose .5% eye drops versus use of 0.5% carboxy methylcellulose eye drop with combination of 0.1% tacrolimus ointment twice daily for treatment of severe dry eyes.**Material and Methods:** 40 patient presenting with severe dry eye were selected randomly. They were divided into 2 groups. Group I received CMC.5% eye drops four times a day and group II received of 0.1%tacrolimus ointment two times daily and .5% CMC eye drops 4times a day. All patients were evaluated on day 0, 2 weeks, 1 month, 3 month and 6 month for relief in ocular symptoms and diagnostic dry eye tests.**Results:** The mean age in group I was 40.72 ± 6.85 years and in group II was 39.2 ± 5.28 years. Ocular discomfort, dryness and tearing were seen in all the cases. Comparison of different parameters after six months of treatment between group I and II showed that the comparision of net score in two groups is statistically significant($p < 0.05$). **Conclusion:** There was statistically significant difference between the outcome of two groups.Group 2 patients who used combination of of 0.1%tacrolimus ointment two times daily along with CMC 0.5% eye drops 4 times a day were better relieved as compared to patients in group 1 who used 0.5% CMC eye drops four times daily for treatment of severe dry eyes

Keywords: Carboxymethylcellulose, Tacrolimus, Dry eye

Introduction

Dry eye is a multifactorial disease of the tears and ocular surface that results in symptoms of discomfort, visual disturbance, and tear film instability with potential damage to the ocular surface. It is accompanied by increased osmolarity of the tear film and inflammation of the ocular surface[1]. Dry eye is one of the most common causes of ocular morbidity in patients presenting to an ophthalmology outpatient department. Approximately one out of seven individuals aged 65–84 years report symptoms of dry eye often or all of the time[2].Management of dry eye depends on the cause and severity of the condition.Various strategies have been described for medical management of dry eye; these include, the topical use of lubricants (artificial tear substitutes), topical corticosteroids and anti-inflammatory therapies, cyclosporine ophthalmic emulsion, tacrolimus ointment and the systemic use of antioxidants (e.g., omega-3 fatty acids)[1,2].Artificial tears are aqueous solutions containing polymers that determine their viscosity, retention time, and adhesion to the ocular surface. Various polymers currently in use include cellulose derivatives (e.g., hydroxypropyl methylcellulose [HPMC], carboxymethylcellulose [CMC]), polyvinyl derivatives (e.g.,polyvinyl alcohol), chondroitin sulfate, and sodium hyaluronate. In mild-to-moderate cases, they are the mainstay of treatment. Artificial tears act by replenishing the deficient aqueous layer of the tear film and diluting the inflammatory cytokines[2,3]. A novel treatment therapy for severe dry eye cases with potent anti-inflammatory effects as well as sufficient safety is needed. Tacrolimus(FK 506) is a macrolactam derivative with immuno modulatory and anti-inflammatory activity[4]. Produced by the fungus *Streptomyces tsukubaensis*, it suppresses T cell activation and IL-2 production by binding to an immunophilin and inhibiting the enzymatic activity of calcineurin[4,5]. Extensive testing has shown systemic absorption of tacrolimus to be below quantifiable levels with no evidence of cancer risk or significant local side effects and only occasional reports of transient burning or pruritus at the application site[6].Topical tacrolimus ointment is commercially available in two strenghts 0.03% and 0.1%[7].Topical tacrolimus 0.03% skin ointment has been used effectively for inflammatory conditions of the anterior segment[8-11]. The good safety profile of 0.1% tacrolimus ophthalmic suspension based on the low blood concentration of tacrolimus, coupled with demonstrated better efficacy, make it an important tool for treating severe dry eye cases. Therefore we chose 0.1% tacrolimus ointment in this study.Side effects noted in use of tacrolimus ointment are burning sensation, activation of herpes simplex dendritic keratitis and development of molluscum contagiosum[12,13].There is lack of studies regarding this topic in this area so we did this study to see efficacy of 0.1% tacrolimus ointment in treatment of severe dry eye cases.

Material and Methods

A comparative prospective study was carried out at Saraswathi Institute Of Medical Sciences Anwarpur(Hapur).Patients were enrolled from February 2019 to September 2019. 20 patients i.e 40 eyes were included in each group presenting with severe dry eye in eye OPD.Patients were randomly divided in two groups Inclusion criteria: 1. Patients with severe dry eye willing to participate in the study and followup

Exclusion criteria

Patients with trachoma 2.Patients with infectious diseases of eye 3.Patients with hypersensitivity to tacrolimus 4. Patients who had less than 6 months follow up 5.Systemic administration of immuno supressants within 2 weeks prior to study.6.pregnant or lactating females7.patients with any cardiac,renal or hepatic disease or diabetes.This study was conducted in compliance with the Declaration of Helsinki.Study was approved by ethical committee of the institute. A valid written consent was taken from patients after explaining study to them. Detailed history was taken. Appropriate laboratory work up was done. Group 1 where patients used carboxy methyl cellulose .5% eye drops four times a day for treatment of severe dry eye. Group 2 in which patients used 0.5% carboxy methyl cellulose eye drops four times daily along with .1% tacrolimus ophthalmic ointment twice daily in treatment of severe dry eyes. All patients were evaluated on day 0, 2 weeks, 1 month, 3 month and 6 month for relief in ocular symptoms and diagnostic dry eye test were done. Diagnostic dry eye test included SCH—Schirmer's test, TBUT—tear breakup time, FLU—fluorescein stain,Rose Bengal staining and marginal tear strip test.Each ocular symptoms(ocular discomfort,foreign body sensation,itching,dryness, photophobia, lacrimation) and dry eye test were scored from 0 to 3 depending on severity and combined score of all symptoms and test was calculated on each follow up visit for each eye individually of each patient in both groups. Net score was calculated as difference between total score (of all symptoms and test) on day 0 and total score at 6 month follow up. Net score actually gives improvement score after use of drug for 6 months in both groups. Net score is then compared in both groups to find the comparative efficacy of drugs in both groups.Net score in both groups was compaired using unpaired t test.

Results

Table 1: Distribution of cases as per age and sex

Parameters	Group I	Group II
Total cases	20	20
Age (Mean±SD)	40.72 ± 6.85	39.2 ± 5.28
Gender (M:F)	11:9	10:10

The mean age in group I was 40.72 ± 6.85 years and in group II was 39.2 ± 5.28 years.Two groups were comparable with regards to age and sex in distribution of patients

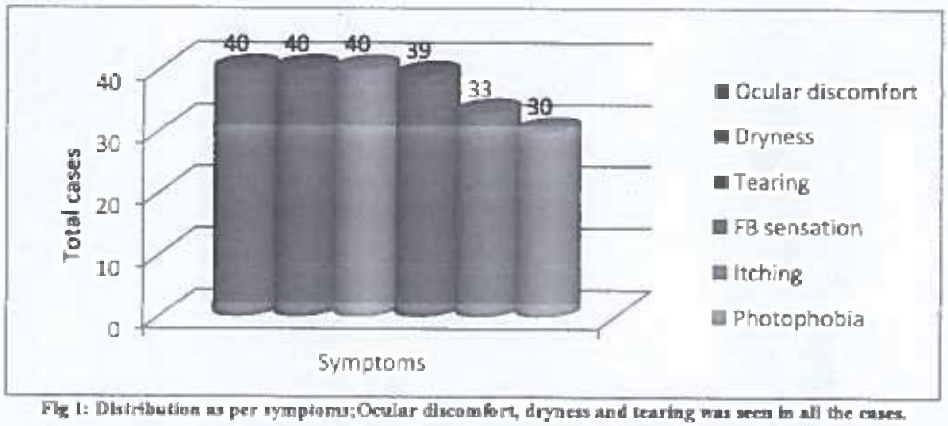

Fig 1: Distribution as per symptoms;Ocular discomfort, dryness and tearing was seen in all the cases.

Table 2: Parameters in both the groups on day 0

Parameters	Group I Mean score	Group II Mean score
Marginal tear strip test	1.75	1.55
SCH	1.72	2.0
TUBT	1.67	1.7
FLU	1.67	1.65
Rose Bengal staining	1.72	1.92
Ocular discomfort	2.20	2.02
Foreign body sensation	2.0	1.87
dryness	2.25	2.02
Itching	1.40	1.80
Photophobia	1.35	1.62
Tearing	1.87	1.65

SCH—Schirmer's test, TBUT—tear breakup time, FLU—fluorescein stain

Table 3: Different parameters in group I and group II after 6months

Parameters	Group I Mean score	Group II Mean score
Marginal tear strip test	0.72	0.15
SCH	0.55	0.30
TUBT	0.25	0.27
FLU	0.40	0.05
Rose Bengal staining	0.42	0.25
Ocular discomfort	0.65	0.32
Foreign body sensation	0.65	0.37
dryness	0.72	0.42
Itching	0.20	0.07
Photophobia	0.35	0.15
Tearing	0.85	0.40

Table 4: Comparision of score parameters between group 1 and group 2 of each ocular symptom and dry eye test between day 0 and 6 month

Parameters	Group 1 (Mean Change Score)	Group 2(Mean Change Score)
Marginal tear strip test	1.03	1.40
Schirmer test	1.17	1.70
TBUT	1.42	1.43
FLU	1.27	1.60
Rose Bengal staining	1.30	1.67
Ocular discomfort	1.55	1.70
Foreign body sensation	1.35	1.50
Dryness	1.53	1.60
Itching	1.20	1.10
Photophobia	1.00	1.45
Tearing	1.02	1.25

Net score-difference between total score of each ocular symptom and dry eye test between day zero and 6 month.
Mean net score in group 1=13.75
Mean net score in group 2=16.45
Net score in group 2 is more than group 1
The difference in net score of 40 eyes from each group was found to be statistically significant $p<0.05$(unpaired t-test)

Discussion

Dry eye is a common complaint among middle-aged and older adults and its prevalence increases progressively with age[14-16]. Studies from India reported that the prevalence varies between 18.4% and 53 % [17-19]. This was a comparative study conducted on 40 severe dry eye cases presenting to eye OPD. The mean age in group I was 40.72 ± 6.85years and group II was 39 ± 5.28 years respectively. Similar study was concluded by Moawad P et al[20] In the present study the male to female ratio was 1:1 with 21 (52.5%) males and 19 (47.5%) females. Majority of patients reported dramatic symptomatic relief during treatment period.Patients showed improvement in terms of decrease in score values at different follow ups.All patients had relief in foreign body sensation,discomfort,tearing,photophobia,dryness and itching.At the end of study i.e.at 6 months,eyes having score 03 for different symptoms were 0 in both groups,those with moderate score 02 for different symptoms were more in group 1 as compared to group 2 and greater percentage of eyes from group2 had score 0 for different ocular symptoms. In the present study ocular discomfort, dryness, tearing was seen in all cases. While in a study by Kamalakshy J et al[21] most frequent ocular surface symptom in confirmed cases of dry eye was itching. In another study by Lee AJ et al conducted in Indonesia burning sensation was the most common symptom [14]. In this study use of topical tacrolimus0.1% ointment and CMC 0.5% in group II showed significant improvement in all the parameters specially TBUT and SCH which was in accordance to other studies like Moawad P et al[20] and MoscoviciBK et al[22] and Aoki S et al[23].This is explained by the fact that the ocular surface, lacrimal glands and the neuronal feedback loop that make up a single functional unit for the maintenance of ocular surface homeostasis leading to improvement of the ocular surface.Moscoviki et al[22] showed significant decrease in sandy or gritty feeling, dryness, itching and blurred vision in patients treated with tacrolimus.03%.A study by Marco E S et al[23]showed improvement in signs and symptoms of dry eye diseases in patients treated with tacrolimus 03% .In our study results show better relief in all ocular symptoms in group 2.Therefore our study is in accordance with study of Moscoviki et al[22] and Marco E S et al[23].

Tacrolimus has immunomodulatory role so it effectively improves tear secretion in immune origin dry eye patients.Mean net score in group 2 was more than group 1 indicating more improvement in group 2.Difference in net score in both groups was found to be statistically significant. A recent publication by Ashena Z et al[25] also mentions the immunomodulatory role of 0.3% tacrolimus in treatment severe dry eye cases.In our study, only two patients from group 2 showed burning sensation after use of tacrolimus ointment but burning sensation subsided gradually and no patient discontinued the drug use which was consistent with study by Rustin et al[6].

Conclusion

Present study concludes that there is statistically significant difference in response(in terms of improvement in tear film profile tests and ocular symptoms) in patients treated with combination of tacrolimus 0.1% ointment and CMC 0.5% drops as compared to patients treated with .5% CMC eye drops only. It also strengthens the fact that topical tacrolimus0.1% twice daily plus CMC 0.5% has no adverse effect.

Prevalence and Causes of Visual Impairment in an Area of Western Uttar Pradesh

Prerana Agarwal[1], D. J. Pandey[2]

[1]Assistant Professor, [2]Professor, Department of Ophthalmology, Saraswathi Institute of MedicalSciences, Hapur U.P. (India)

ABSTRACT

Introduction: It has been recently estimated by the World Health Organization (WHO) that there are 285 million visually impaired people worldwide, among whom 39 million are blind.

Aims and Objectives: To study Prevalence and causes of visual impairment in an area of western Uttar Pradesh.

Methodology: This was cross-sectional study in the 3217Patients attending eye OPD in Saraswathi Institute of ophthalmology Hapur from Jan2018 to October 2018. Patients above 30 years of age were enrolled for study.2234 patients fit the inclusion criteria.2016 participated in study. Detailed ocular examination was done. visual impairment was defined as visual acuity less than 6/18 in better eye. The details of patients and all routine investigations were carried out. The causes of visual impairment were found out. Data entered to excel sheet and analyzed by Excel software for windows 10.

Result: In our study we have seen that the majority of the patients were in the age group of 60-70 (39.14%), followed by 50-60 in 28.42%, 40-50 were 12.40%, >70 were 11.66%, 30-40 were 8.38%. The majority of the patients were Male i.e. 55.85% and Female were 44.15% Out of 2016 patients 665 i.e. 33% were having visual impairment. The most common cases were Cataract - 39%; Uncorrected refractive errors- 21%; Retinal diseases like diabetic retinopathy and age related macular degeneration- 13%; Trauma- 9%; Glaucoma- 8%; Iridocyclitis- 6%; Corneal opacity -4%.

Conclusion: It can be concluded from our study that majority of the patients were in the age group of 60-70, the majority of the patients were Male. The prevalence of VI was 33% and most common causes were Cataract, Uncorrected, refractive errors, Retinal diseases, Trauma, Glaucoma, Iridocyclitis, Corneal opacity.

Keywords: *Visual Impairment (VI), Cataract, Refractive errors, Retinal diseases, Corneal opacity, Glaucoma*

Introduction

It has been recently estimated by the World Health Organization (WHO) that there are 285 million visually impaired people worldwide, among whom 39 million are blind.[1] In India, 62 million people are estimated to be visually impaired, 8 million of them being blind.[1] Visual impairment is currently defined as presenting visual acuity of less than or equal to 6/18 in the better eye, whereas blindness is defined as presenting visual acuity of less than or equal to 3/60 in the better eye.[2] Disability is an umbrella term for impairments, activity limitations, and participation restrictions.[2] The registration of blindness or visual impairment entails a certification of the disabled individuals based on which social services are coordinated. It also provides contemporary data regarding the incidence and causes of visual impairment for analysis and to set up priorities for their prevention. Registration of blindness is voluntary in India and the certificate is issued by a duly constituted medical board of experts, which includes an

ophthalmologist. All individuals with visual disability of 40% or higher are entitled to various concessions and job benefits according to guidelines issued by the Ministry of Social Justice and Empowerment of the Government of India.[3] According to the 58th round data from the National Sample Survey Organization (NSSO) in India, blindness and visual impairment were found to account for 10.88% and 15.27%, respectively, of all categories of disabilities.[4] So we have found out causes of visual impairment in an area of western Uttar Pradesh.

Methodology

This was cross-sectional study in the 3217 patients attending Eye OPD in Saraswathi Institute of ophthalmology Hapur from Jan2018 to October 2018. Patients above 30 years of age were enrolled for study.2234 patients fit the inclusion criteria.2016 participated in study. Detailed ocular examination was done. Visual impairment was defined as visual acuity less than 6/18 in better eye. The details of the patients and all routine investigations were carried out. The causes of visual impairment were found out. Data entered to excel sheet and analyzed by Excel software for windows 10.

Result

3217 Patients attended Eye OPD in Saraswathi Institute of ophthalmology Hapur from Jan2018to October 2018. Patients above 30 years of age were enrolled for study.2234 patients fit the inclusion criteria.2016 participated in study.

Table 1: Distribution of the patients as per the age

Age	No.	Percentage (%)
30-40	169	8.38
40-50	250	12.40
50-60	573	28.42
60-70	789	39.14
>70	235	11.66
Total	2016	100.00

The majority of the patients were in the age group of 60-70 (39.14%), followed by

50-60 in 28.42%, 40-50 were 12.40%, >70 were 11.66%, 30-40 were 8.38%.

Table 2: Distribution of the patients as per the sex

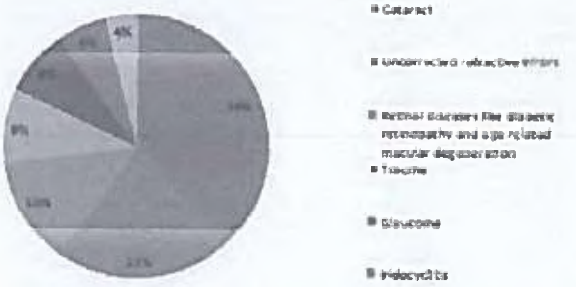
Sex	No.	Percentage (%)
Male	1126	55.85
Female	890	44.15
Total	2016	100.00

The majority of the patients were Male i.e. 55.85% and Female were 44.15%

Table 3: Distribution of the patients as per the Visual impairment

Visual impairment	No.	Percentage (%)
Cataract	259	39%
Uncorrected refractive errors	140	21%
Retinal diseases like diabetic retinopathy and age related macular degeneration	86	13%
Trauma	60	9%
Glaucoma	53	8%
Iridocyclitis	40	6%
Corneal opacity	27	4%
Total	665	100%

Out of 2016 patients 665 i.e. 33% were having visual impairment. Most common causes were Cataract - 39%; Uncorrected refractive errors- 21%; Retinal diseases like diabetic retinopathy and age related macular degeneration- 13%; Trauma- 9%; Glaucoma- 8%; Iridocyclitis- 6%, Corneal opacity -4%.



Graph 1: Distribution of as per the patients as per the Visual impairment

Discussion

Eye diseases, vision loss and resulting disability remain major public health concerns.[5] It has been

estimated that globally 253million people are visually impaired out of which 36million are blind and 217million have moderate to severe visual impairment (VI). [6] Though there has been a decline noted in prevalence of blindness over recent times, blindness has actually increased in absolute terms owing to increase in numbers of older people with rise in life expectancy.[6] Much of this global burden is distributed unevenly and some regions have higher burden compared with others. The south Asia (that includes India) region contributes maximum to global blindness and moderate or severe visual impairment burden. It is estimated that south Asia has 12million blind people and 61million people with moderate or severe Visual Impairment[6] The age standardised prevalence of moderate or severe Visual Impairment in South Asia is three times higher than high-income regions.[6] Much of the load of blindness (80%) has been attributed to avoidable causes that can be either prevented or corrected easily.[5] The maximum Visual Impairment is seen in older adult population that is after 50years of age.86% of those blind and 80% of those with moderate or severe Visual Impairment are older than 50years[6]. The global eye health action plan 2014–2019, endorsed by the 66th World Health Assembly, charted out broad eye health programmatic components. A vital target was set to achieve reduction in prevalence of avoidable Visual Impairment by one-quarter until 2019 against baseline values in year 2010. One of the key objectives included under this plan was to undertake epidemiological surveys on Visual Impairment at regular intervals nationally and subnationally, so as to generate evidence about magnitude and causes of Visual Impairment.[7] According to recent global estimates, India records one of the highest prevalence of Visual Impairment. The age-standardized prevalence of blindness and moderate or severe VI in India is 4% and 17%, respectively, among adults aged 50 and more.[6] The last nationwide blindness assessment undertaken in India was published way back in 2008.[8]

In our study we have seen that the majority of the patients were in the age group of 60-70 i.e 39.14%, followed by 50-60 (28.42%), 40-50 (12.40%), >70(11.66%), 30-40 (8.38%). Majority of the patients were Male i.e. 55.85% and Female were 44.15%. Out of 2016 patients 665 i.e. 33% were having visual impairment. The most common cases were Cataract - 39%; Uncorrected refractive errors- 21%; Retinal diseases like diabetic retinopathy and age related macular degeneration- 13%; Trauma- 9%; Glaucoma- 8%; Iridocyclitis- 6%; Corneal opacity -4%.

Sumit Malhotra et [13] al found Visual Impairment to be 24.5% (95% CI 21.1 to 26.3) in their study. This is almost similar to recent population-level estimates from southern states of India. The reported prevalence of Visual Impairment in adults aged >50 years in a newly formed southern state of Telengana was 23.5% (95% CI 22.1 to 25.0).[12] The Andhra Pradesh Rapid Assessment of Visual Impairment study that included both rural and urban clusters estimated prevalence of Visual Impairment as 23.1% (95% CI 21.8 to 24.5).[13] They also found 87% of VIisual Impairment was contributed by two causes—uncorrected refractive errors (50%) followed by cataract (37%). The most common causes for blindness (57%) and severe Visual Impairment (70%) was cataract. This is consistent with other studies[9 10 11] where 80%–90% of Visual Impairment is attributed to these two causes. Globally, majority of Visual Impairment is contributed by uncorrected refractive errors followed by cataract. Cataract and uncorrected refractive errors combined contributed to 55% of blindness and 77% of vision impairment in adults aged 50 years and older in 2015.[12] Also, globally in 2015, the leading causes of moderate or severe Visual Impairment in those aged 50 years and older were uncorrected refractive errors (52%) followed by cataract (25%).

Conclusion

It can be concluded from our study that majority of the patients were in the age group of 60-70yrs of age and majority of the patients were Male. The prevalence of Visual Impairment was 33% and most common causes were Cataract, Uncorrected, refractive errors, Retinal diseases, Trauma, Glaucoma, Iridocyclitis, Corneal opacity

Comparative Study of CMC 0.5% Eye Drops versus Combination of .05% Cyclosporin Ophthalmic Emulsion and 0.5% CMC Eye Drops in Dry Eye Disorders

Prerana Agarwal[1], D.J. Pandey[2]

[1]Assistant Professor, [2]Professor, Department of Ophthalmology, Saraswathi Institute of Medical Sciences, Hapur, U.P (India)

Abstract

Background: Dry eye disease is a common disorder provoking changes in tear film and ocular surface. Untreated dry eye could cause ocular infections, corneal ulcer and blindness. Only a few drugs are authorized so far for the treatment of dry eye disease and the possibilities of evolution in this sector are immense. **Objectives:** Compare efficacy of carboxy methyl cellulose .5% eye drops with combination of 0.5% carboxy methyl cellulose eye drops and .05% cyclosporin ophthalmic emulsion for treatment of dry eyes. **Material and Method:** 40 patient presenting with dry were selected randomly. They were divided into 2 groups. Group I received CMC.5% eye drops four times a day and group II received .05% Cyclosporin ophthalmic emulsion two times daily and .5% CMC eye drops 4times a day. All patients were evaluated on day 0, 2 weeks, 1 month, 3 month and 6 month for relief in ocular symptoms and diagnostic dry eye tests. **Results:** The mean age in group I was 39.72 ± 6.85 years and in group II was 40.2 ± 5.28 years. Ocular discomfort, dryness and tearing were seen in all the cases. Comparison of different parameters after six months of treatment between group I and II showed that the comparision of net score in two groups is statistically significant($p < 0.05$). **Conclusions:** There was statistically significant difference between the outcome of two groups.Group 2 patients who used combination of cyclosporin0.05% ophthalmic emulsion two times daily along with CMC 0.5% eye drops 4 times a day were better relieved as compared to patients in group 1 who used 0.5% CMC eye drops four times daily for treatment of dry eyes.

Keywords: *Carboxymethylcellulose, Cyclosporine, Dry eye*

Introduction

"Dry eye is a multifactorial disease of the tears and ocular surface that results in symptoms of discomfort, visual disturbance, and tear film instability with potential damage to the ocular surface. It is accompanied by increased osmolarity of the tear film and inflammation of the ocular surface.[1] Dry eye is one of the most common causes of ocular morbidity in patients presenting to an ophthalmology outpatient department. Approximately one out of seven individuals aged 65–84 years report symptoms of dry eye often or all of the time.[2]Management of dry eye depends on the cause and severity of the condition.Various strategies have been described for medical management of dry eye, these include, the topical use of lubricants (artificial tear substitutes), topical corticosteroids and anti-inflammatory therapies, cyclosporine ophthalmic emulsion, and the systemic use of antioxidants (e.g., omega-3 fatty acids).[1,2]

Artificial tears are aqueous solutions containing polymers that determine their viscosity, retention time, and adhesion to the ocular surface. Various polymers currently in use include cellulose derivatives (e.g., hydroxypropyl methylcellulose [HPMC], "carboxymethylcellulose [CMC]), polyvinyl derivatives (e.g., polyvinyl alcohol), chondroitin sulfate, and sodium hyaluronate. In mild-to-moderate cases, they

Corrosponding author-
Dr. Prerana Agarwal, MS,
Assistant Professor, Department of Ophthalmology, Saraswathi Institute of Medical Sciences Hapur, U.P (india) Email: docpremaagarwal@gmail.com

are the mainstay of treatment. Artificial tears act by replenishing the deficient aqueous layer of the tear film and diluting the inflammatory cytokines.[2,3] cyclosporine 0.05% emulsion has been approved by the US FDA for its treatment. Given the role of inflammation in dry eye, it makes sense that anti-inflammatory agents have been evaluated in its treatment.[4]

These is lack of studies regarding this topic in this area so we did this study to see efficacy of these two treatment over each other

Material and Method

A comparative prospective study was carried out at Saraswathi Institute Of Medical Sciences Anwarpur(Hapur). Patients were enrolled from February 2018 to July 2018. 20 patients i.e 40 eyes were included in each group presenting with dry eye in eye OPD.Patients were randomly divided in two groups. Detailed history was taken. Appropriate laboratory work up was done. Group 1 where patients used carboxy methyl cellulose .5% eye drops for treatment of dry eye. Group 2 in which patients used 0.5% carboxy methyl cellulose eye drops along with .05% cyclosporin ophthalmic emulsion for treatment of dry eyes. All patients were evaluated on day 0, 2 weeks, 1 month, 3 month and 6 month for relief in ocular symptoms and diagnostic dry eye test were done. Diagnostic dry eye test included SCH—Schirmer's test, TBUT—tear breakup time, FLU—fluorescein stain,Rose Bengal staining and marginal tear strip test. Each ocular symptom(ocular discomfort,foreign body sensation,itching,dryness,photophobia,lacrimation) and dry eye test were scored from 0 to 3 depending on severity and combined score of all symptoms and test was calculated on each follow up visit for each eye individually of each patient in both groups. Net score was calculated as difference between total score (of all symptoms and test) on day 0 and total score at 6 month follow up. Net score actually gives improvement score after use of drug for 6 months in both groups. Net score is then compared in both groups to find the comparative efficacy of drugs in both groups.Net score in both groups was compaired using unpaired t test This study was approved by institutional ethics committee

Results

Table 1: Distribution of cases as per age

Parameters	Group I	Group II
Total cases	20	20
Age (Mean±SD)	39.72 ± 6.85	40.2 ± 5.28
Gender (M:F)	11:9	10:10

The mean age in group I was 39.72 ± 6.85 years and in group II was 40.2 ± 5.28 years.

Diagram 1: Distribution as per symptoms.

Ocular discomfort, dryness and tearing was seen in all the cases.

Table 2: Parameters in both the groups on day 0

Parameters	Group I Mean score	Group II Mean score
Marginal tear strip test	1.65	1.55
SCH	1.72	2.0
TUBT	1.67	1.7
FLU	1.67	1.65
Rose Bengal staining	1.72	1.92
Ocular discomfort	2.20	2.02
Foreign body sensation	2.0	1.87
dryness	2.25	2.02
Itching	1.40	0.80
Photophobia	1.35	1.22
Tearing	1.97	1.65

SCH—Schirmer's test, TBUT—tear breakup time, FLU—fluorescein stain

Table 3: Different parameters in group I and group II after 6months

Parameters	Group I Mean score	Group II Mean score
Marginal tear strip test	0.62	0.15
SCH	0.55	0.30
TUBT	0.25	0.27
FLU	0.40	0.05
Rose Bengal staining	0.42	0.25
Ocular discomfort	0.65	0.32
Foreign body sensation	0.65	0.37
dryness	0.72	0.42
Itching	0.20	0.07
Photophobia	0.35	0.12
Tearing	0.95	0.40

Table 4. Comparision of score parameters between group 1 and group 2 of each ocular symptom and dry eye test between day 0 and 6 month

Parameters	Group 1 (mean change score)	Group 2(mean change score)
Marginal tear strip test	1.03	1.40
Schirmer test	1.17	1.70
TBUT	1.42	1.43
FLU	1.27	1.60
Rose Bengal staining	1.30	1.67
Ocular discmfort	1.55	1.70
Foreign body sensation	1.35	1.50
Dryness	1.53	1.60
Itching	1.20	0.73
Photophobia	1.00	1.10
Tearing	1.02	1.25

Net score-difference between total score of each ocular symptom and dry eye test between day zero and 6 month

Mean net score in group 1=13.75

Mean net score in group 2=15.7

Net score in group 2 is more than group 1

The difference in net score of 40 eyes from each group was found to be statistically significant $p<0.05$(unpaired t-test)

Discussion

Dry eye is a common complaint among middle-aged and older adults and its prevalence increases progressively with age[9-11] Studies from India reported that the prevalence varies between 18.4% and 63.%[14,15,16]

This was a comparative study conducted on 40 dry eye cases presenting to eye OPD. The mean age in group I was 36.72 ± 6.85years and group II was 38 ± 5.28 years respectively. Similar study was concluded by Shah S et al.[10] In the present study the male to female ratio was 1:1 with 21 (52.5%) males and 19 (47.5%) females. This was in accordance with Shah S et al.[10] where the ratio was 1:1. On the contrary Female dominance was reported by Behera S et al. [11]

In the present study middle age formed 60% of the study grup patients. Similar higher middle age population was seen with Shah S et al[10], Kamalakshy J et al[12] and Titiyal JS et al[13] study.

Majority of patients reported dramatic symptomatic relief during treatment period.Patients showed improvement in terms of decrease in score values at different follow ups.All patients had relief in foreign body sensation,discomfort,tearing,photophobia,dryness and itching.At the end of study i.e.at 6 months,eyes having score 03 for different symptoms were 0 in both groups,those with moderate score02 for different symptoms were more in group 1 as compared to group2 and greater percentage of eyes from group2 had score 0 for different ocular symptoms

In the present study ocular discomfort, dryness, tearing was seen in all cases. While in Kamalakshy J et al[12] most frequent ocular surface symptom in confirmed cases of dry eye was itching. In another study by Lee AJ et al[14] conducted in Indonesia burning sensation was the most common symptom.

In this study use of topical cyclosporine 0.05% and CMC 0.5% in group II showed significant improvement in all the parameters specially TBUT which was in accordance to other studies like Shah S et al[16], Byun YJ et al[17], Sall K et al.[18]This is explained by the fact that the ocular surface, lacrimal glands and the neuronal feedback loop that make up a single functional unit for the maintenance of ocular surface homeostasis leading to improvement of the ocular surface Sall K et al.[19]

Sall K et al[19] showed significant decrease in sandy or gritty feeling, dryness, itching and blurred vision in patients treated with cyclosporine .05%.A study by Cross WD et al[22]showed improvement in signs and symptoms of dry eye diseases in patients treated with cyclosporine 2% Study by Sodhi et al [23] showed statistically significant improvement in only lacrimation and photophobia in patients treated with cyclosporine 2%while none of the ocular complaints showed significant improvement in patients treated with artificial tear eye drops .In our study results show better relief in all ocular symptoms in group 2.Therefore our study is in accordance with study of Sall K et al [19] Cross WD et al[22] but not in accordance with study of Sodhi et al [23].Difference could be because of the fact that all patients enrolled in study by Sodhi et al were of non immune origin and cyclosporine has immunomodulatory role.

Mean net score in group 2 was more than group 1 indicating more improvement in group 2.Difference in net score in both groups was found to be statistically significant.A recent study by Sal KN et al on American patients has also shown improvement in ocular symptoms and tear film tests value with combination of cyclosporine and artificial tear eye drops[24]

In our study, none of the patients showed any drug related adverse effects which was consistent Shah S et al[16], Kinoshita S et al[20] and Small DS et al.[21]

Conclusion

Present study concludes that there is statistically significant difference in response(in terms of improvement in tear film profile tests and ocular symptoms) in patients treated with combination of cyclosporine 0.05% and CMC 0.5% drops as compared to patients treated with .5% CMC eye drops only.. It also strengthens the fact that topical cyclosporine A 0.05% twice daily plus CMC 0.5% has no adverse effect .

Conflict of Interest-NIL

Source of Funding-The study was carried out at Saraswathi Institute Of Medical Sciences,Hapur and no extra financial support was required

Ethical Clearance-Ethics committee approval was obtained before study

Abstract

Background: Allergic conjunctivitis is an increasingly prevalent allergic reaction having clinical gravity similar to asthma and allergic rhinitis. **Aims and Objectives:** To study Comparison between bepotastinebesilate 1.5% eye drop versus olopatadine hydrochloride 0.2% eye drop in cases of allergic conjunctivitis. **Methodology:** forty consecutive patients presenting from March 2018 to July 2018 in Eye OPD at Saraswathi institute of medical sciences Hapur, with symptoms of ocular itching associated with allergic conjunctivitis a were enrolled in this study. Here, Group A (1st drug B and 2nd drug O) (n=20), Group B(1st drug O and 2nd drug B) (n=20), where Bepotastinebesilate 1.5% eye drop, OD Olopatadine hydrochloride 0.2% eye drop. 1stvisit done after 1st day of starting the drug, 2nd visit (day 16) after use of first medication, 3rd Visit (day 39) after use of second medication. The itching symptoms and all Ocular allergy symptoms were graded on 5 points scale. The statistical analysis done by unpaired t-test and calculated by SPSS 19 version software. **Result:** the majority of the patient were in the age group of 40-50 i.e. 60% followed by 30-40-17.5%, 20-30 were 12.5%, 50-60 were 10%. The mean age was (Mean ±SD) 41.68 ± 8.51. The majority of the patients were females 65% and males were 35%. At first visit the symptoms itching were comparable with each other as Ocular itching grading on 5 point scale was 4.2 ± 0.52 and 4.35 ± 0.49 in group A and B respectively (t=0.94 df=38,p>0.05) ; on2nd visit (day 16)after use of first medication the relief score in ocular itching was significantly higher in Group A i.e. 3.9± 0.79 versus 2.85 ± 0.67 in group B (t=4.9 df=38,P<0.0001), 3rd Visit (day 39)after use of second medication the score was significantly higher in Group B i.e. 3.7±0.47 as compared to 2.65 ±0.81in group A (t=5.0 df=38, P<0.0001). At 2nd visit (day 16) after use of first medication the relief score in all ocular allergy symptoms was significantly higher in Group A i.e. 3.55± 0.69 as compared to2.65± 0.75 in group B (t=5.23, df=38, p<0.0001) , at 3rd Visit (day 39)after use of second medication the score was significantly higher in Group B i.e. 3.2±0.70 as compared to 2.3±0.73in group A (t=4.92 , df=38,p<0.0001). **Conclusion:** at the baseline both the drugs were comparable with each other, at second visit the score was variable but at the end the response with respect to score and patients preference the bepotastinebesilate 1.5% was found superior to olopatadine hydrochloride 0.2% with respect to treatment of allergic conjunctivitis.

Key Word: bepotastinebesilate 1.5% ,olopatadinehydrochloride 0.2% , allergic conjunctivitis

INTRODUCTION

Allergic conjunctivitis is an increasingly prevalent allergic reaction having clinical gravity similar to asthma and allergic rhinitis. Currently around, 40% of global population is suffering from allergic conjunctivitis (Azari and Barney, 2013)[1]. Exposure to particulate matter less than 2.5 µm can lead to allergic reactions. Studies have reflected impact of high PM2.5 levels on increasing prevalence of allergic conjunctivitis among countries like Japan (Mimura et al, 2014)[2]. Among the case countries, 40% of the population in Japan is suffering from conjunctivitis and the prevalence is increasing rapidly

How to cite this article: Prerana Agarwal, S D Tayal. Comparison between bepotastinebesilate 1.5% eye drop versus olopatadine hydrochloride 0.2% eye drop in cases of allergic conjunctivitis. *MedPulse International Journal of Ophthalmology*. November 2018; 8(2): 28-32. https://www.medpulse.in/Ophthalmology/

(Rosario andBielory, 2011)[3]. This is due to change in lifestyle and environmental factors. Further, in case of Africa, the prevalence was found to be 32% and was found most prevalent among children aged between 1-16 years (38.4%) (Malu, 2014)[4]. On the other hand in USA and Australia it was found to be 20%. Similarly in case of UK it was found to be 17.5% (Perkin, Bader, Rudnicka, Strachan, and Owen, 2015)[5]. In comparison the prevalence in India is on higher side with 25.5% population affected by this allergy (Puri, Ashat, Singh Sarpal, Kaur, and Kumar, 2013). High level of allergy in India is because of high pollution levels in the country. Critical review of the situation reflects that the prevalence is common among children studying in government schools due to poor hygiene. Further, in India, consequence of allergic conjunctivitis is blindness (prevalent among 1.84%) and corneal blindness (prevalent among 8.6%) (Dandona and Dandona, 2001, adii, C. (2016))6,7. So with such a significant health problem of allergic conjunctivitis in India, we have studied whether bepotastinebesilate 1.5% eye drop or olopatadine hydrochloride 0.2% eye drop in cases of allergic conjunctivitis is superior in the management of Allergic conjunctivitis as perceived by the patients

METHODOLOGY

forty consecutive patients presenting from March 2018 to July 2018 in Eye OPD at Saraswathi institute of medical sciences Hapur, with symptoms of ocular itching associated with allergic conjunctivitis were enrolled in this study. Patients with age more than 18 years, had a diagnosis of allergic conjunctivitis with no concurrent unrelated ocular diseases, had no plans to undergo ocular surgery during the study period were included into the study while patients who had a known hypersensitivity to either agent, history of alcohol or drug abuse, positive history of an ocular herpetic infection, an active ocular infection, or any significant illness , Patients who were actively taking steroids or antihistamines within 7 days prior to enrollment, pregnant, planning to become pregnant, or nursing/lactating were excluded. The enrolled patients were assigned sequentially according to a computer-generated randomization list to receive bepotastinebesilate 1.5% or olopatadine hydrochloride 0.2% in a 1:1 ratio. Patients instilled either bepotastinebesilate 1.5% twice daily (at approximately 8 am and 5 pm) or olopatadine hydrochloride 0.2% once daily (at approximately 8 am) for 16 days. Following a 7-day washout period during which only preservative-free artificial tears were used twice daily, patients were crossed-over to the other treatment for 16days. Each treatment was provided in the packaging originally approved by the Food and Drug Administration, but the single investigator was masked as to which treatment the patient was currently using. Patients were instructed to use gentle eye lid closure for at least two minutes after dosing and to repeat instillation of a single drop if there was uncertainty as to whether successful instillation of the treatment had occurred In addition, patients wearing contact lenses were encouraged to use glasses during the study period. Patients completed an office questionnaire at visit 1 (baseline, day 0), visit 2 (day 16), and visit 3 (day39). During visit 1, prior to dispensing the treatment, patients were asked to rate the following items on a five-point scale: ocular itching associated with allergies; and satisfaction with over-the-counter allergy medication. During visit 2, a different survey questionnaire was administered. Prior to dispensing the second medication, the patients were asked to rate the following items on a five-point scale: ocular itching prior to dosing in the morning; how well the eye drop relieved ocular itching during the day,and the comfort of the drop. The patients were assessed for adverse events. Following the questionnaire, the patients received preservative-free artificial tear drops and were instructed to use the drops twice daily for one week prior to starting the second treatment. On day 23, patients were informed to discontinue using the artificial tear drops and to start using the new treatment for 16days. During visits 2 and 3, the patients were assessed for adverse events. In addition, a final summary questionnaire was given at visit 3. The patients were asked to choose which eye drop provided better all-day relief of ocular itching and was more comfortable. Lastly, the patients were asked to choose which medication they would like to have as a prescription to continue treating their allergic conjunctivitis. During the study period the treatment relieved their ocular itch (graded on a 1–5 scale, with 5 being completely relieved) and how well the treatment relieved all of their ocular allergy symptoms (graded on a 1–5 scale, with 5 being completely relieved). Ocular allergy symptoms included ocular itch, epiphora, conjunctival chemosis, hyperemia, and eye lid edema. Here Group A (1^{st} drug B and 2^{nd} drug O) (n=20), Group B(1^{st} drug O and 2^{nd} drug B) (n=20), where B→Bepotastinebesilate 1.5% eye drop, O→ Olopatadine hydrochloride 0.2% eye drop . 1^{st}visit done (0 day) of starting the drug, 2^{nd} visit (day 16) after use of first medication, 3^{rd} Visit (day 39)after use of second medication. The itching symptoms and all Ocular allergy symptoms was graded on 5 point scale. The statistical analysis done by unpaired t-test and calculated by SPSS 19 version software.

RESULT

Table 1: Distribution of the patients as per the age

Age	No.	Percentage (%)
20-30	5	12.5
30-40	7	17.5
40-50	24	60
50-60	4	10
Total	40	100
Mean ±SD		41.68 ± 8.51

The majority of the patient were in the age group of 40-50 i.e. 60% followed by 30-40-17.5%,20-30 were12.5%, 50-60 were 10%. The mean age was (Mean ±SD) 41.68 ± 8.5

Table 2: Distribution of the patients as per the sex

Sex	No.	Percentage (%)
Male	14	35
Female	26	65
Total	40	100

The majority of the patients were females 65% and males were 35%.

Table 3: Distribution of the patients with respect to symptoms itching on subsequent visits

Ocular itching grading on 5 point scale	Group A (1st drug B and 2nd drug O) (n=20)	Group B(1st drug O and 2nd drug B) (n=20)	p-value
1st visit	4.2 ± 0.52	4.35 ± 0.49	t=0.94 df=38 p>0.05
2nd visit (day 16)after use of first medication	3.9± 0.79	2.85 ± 0.67	t=4.9 df=38 P<0.0001
3rd Visit (day 39)after use of second medication	2.65 ±0.81	3.7±0.47	t=5.0 df=38 P<0.0001

At first visit the symptoms of itching were comparable with each other as Ocular itching grading on 5 point scale was 4.2 ± 0.52 and 4.35 ± 0.49 in group A and B respectively (t=0.94 df=38,p>0.05) ; on2nd visit (day 16)after use of first medication the relief score in ocular itching was significantly higher in Group Ai. e. 3.9± 0.79 versus 2.85 ± 0.67 in group B (t=4.9 df=38, P<0.0001), 3rd Visit (day 39) after use of second medication the relief score in ocular itching was significantly higher in Group B i.e. 3.7±0.47 as compared to 2.65 ±0.81 in group A (t=5.0 df=38, P<0.0001)

Table 4: Distribution of the patients with respect to all ocular allergy symptoms on subsequent visits

All Ocular allergy symptoms (grading on 5 point scale)	Group A (1st drug B and 2nd drug O) (n=20)	Group B(1st drug O and 2nd drug B) (n=20)	p-value
2nd visit (day 16)after use of first medication	3.55± 0.69	2.65± 0.75	t=5.23 , df=38 P<0.0001
3rd Visit (day 39)after use of second medication	2.3±0.73	3.2±0.70	t=4.92 , df=38 p<0.0001

At 2nd visit (day 16) after use of first medication the relief score in all ocular allergy symptoms was significantly higher in Group A i.e. 3.55± 0.69 vs 2.65± 0.75in group B (t=5.23, df=38, p<0.0001), at 3rd Visit (day 39)after use of second medication the relief score in all ocular allergy symptoms was significantly higher in Group B i.e. 3.2±0.70 as compared to 2.3±0.73 in group A (t=4.92 , df=38, p<0.0001).

DISCUSSION

Bepotastine is an H1-antihistamine and an inhibitor of histamine release from mast cells.[9] It is a piperidine derivative, similar to fexofenadine, ebastine, and loratidine.[10] Multiple anti-inflammatory effects have been demonstrated, possibly as downstream mediators of the antihistamine activity. For example, in vitro studies suggest that bepotastine specifically suppresses proinflammatory cytokine production by keratinocytes, including inhibition of CD54 expression.[11] Recent work on guinea pigs showed that bepotastine, along with several other H1-antihistamines, reduces vascular hyper-permeability in both antigen-induced and histamine-induced hyperpermeability models.[12] This work also showed that bepotastine inhibits in vitro eosinophil chemotaxis induced by leukotriene B4, and pretreatment with bepotastine limits conjunctival eosinophil infiltration after topical antigen challenge.[12] The pharmacokinetic properties of bepotastine as an ophthalmic solution are described in Phase I trial data from Japan, and these will be described as reported in the FDA Office of Clinical Pharmacology review of the Japanese data. In a repeated instillation study was performed four-times-a day dosing in both eyes

for 7 days in 12 healthy adult male subjects, half of whom instilled bepotastinebesilate 1.0% and half instilled the 1.5% formulation. Venous blood samples were measured by high-performance liquid chromatography and demonstrated a bepotastine plasma concentration peak 1–2 hours postinstillation. The mean maximum concentration (Cmax) for the 1.5% group was 7.3 ±1.9 ng/mL, which was much lower than the Cmax seen in the Phase I single oral dose trial, even at the lowest tested oral dose (Cmax was 22.4 ± 2.1 ng/mL for the 2.5 mg oral dose). At the clinically relevant, approved Japanese oral dose of 10 mg, the Cmax was 101.3 ± 3.5 ng/mL, which is over 13 times higher than the Cmax seen in the repeated ophthalmic dosing trial. Thus, although there is systemic absorption of the ophthalmic drop, the plasma concentrations are quite low, minimizing the likelihood of systemic adverse effects. Furthermore, plasma concentrations at 24 hours postinstallation were below the quantifiable limit of 2 ng/mL in 11 of 12 subjects. In the oral single-dose study, 75%–90% of the administered dose was secreted in the urine as unchanged drug by 24 hours after administration within the 2.5–40 mg dose range. An additional Phase I study addressed the metabolism of bepotastine by liver microsomes, showing that there was minimal metabolism by CYP3A4, CYP2C9, and CYP2C19, again as reported by the FDA Office of Clinical Pharmacology review of the Japanese data9. Within the relevant concentration range, it was concluded that bepotastine would likely have no effects on concomitantly metabolized drugs involving these enzymes. Finally, a protein-binding Phase I study was performed, demonstrating 55.4% mean plasma protein binding of the drug 1–2 hours after a 10 mg oral dose.[8] This binding level was independent of plasma drug concentration. In our study we have found the majority of the patient were in the age group of 40-50 i.e. 60% followed by 30-40-17.5%, 20-30 were 12.5%, 50-60 were 10%. The mean age was (Mean ±SD) 41.68 ± 8.51. The majority of the patients were females 65% and males were 35%. At first visit the symptoms of itching were comparable with each other as Ocular itching grading on 5 point scale was 4.2 ± 0.52 and 4.35 ± 0.49 in group A and B respectively (t=0.94 df=38,p>0.05) ; on2nd visit (day 16)after use of first medication the relief score in ocular itching was significantly higher in Group A i.e. 3.9± 0.79 versus 2.85 ± 0.67in group B (t=4.9 df=38,P<0.0001), 3rd Visit (day 39)after use of second medication the relief score in ocular itching was significantly higher in Group B i.e. 3.7±0.47 as compared to 2.65 ±0.81 in group A (t=5.0 df=38, P<0.0001). At 2nd visit (day 16)after use of first medication the relief score in all ocular allergy symptoms was significantly higher in Group A i.e. 3.55± 0.69 as compared to 2.65± 0.75 in group B (t=5.23 , df=38,p<0.0001) , at 3rd Visit (day 39)after use of second medication the relief score in all ocular allergy symptoms was significantly higher in Group B i.e. 3.2±0.70 as compared to 2.3±0.73 in group A (t=4.92, df=38,p<0.0001). Craig F McCabe[13] found at study end, 63.3% and 66.7% of patients preferred bepotastinebesilate 1.5% for all-day relief of ocular itching and all-day relief of itchy/runny nose, respectively. At study end, there was no significant difference in the number of patients preferring one treatment over the other for comfort. Overall, 66.7% of patients stated that they would prefer to treat their allergic conjunctivitis with bepotastinebesilate 1.5% over olopatadine hydrochloride 0.2%. Conclusion: Based on their evaluation of therapeutic performance, patients preferred bepotastinebesilate 1.5% over olopatadine hydrochloride 0.2% by two-to-one for the treatment of allergic conjunctivitis.

CONCLUSION

at the baseline both the drugs were comparable with each other , at second visit the score was variable but at the end the response with respect to score and patients preference ,the bepotastinebesilate 1.5% was found superior to olopatadine hydrochloride 0.2% with respect to treatment of allergic conjunctivitis.

Dr. Hemant Jain Assistant Professor, Dr S. N. Medical College, Jodhpur(Rajasthan)

ABSTRACT

INRTODUCTION: Idiopathic clubfoot affects approximately 50,000 children each year and is one of the leading causes of disability in India. Ponseti's technique of casting, tenotomy and bracing is an acceptable method worldwide in its management.

MATERIAL AND METHOD: The Ponseti technique is very slowly picking up in our country, inspite of its ease of usage and compatible results. In this retrospective study of 215 patients enrolled from march 2013 to June 2016. We will be discussing the ponseti's technique in brief, various set-up's where the technique is being adopted and the obstacles faced by parents at each level.

RESULTS: In our study total 37 (17.2%) parents' encountered obstacles. The most frequent obstacles to the Ponseti method in our study are lack of awareness for clubfoot treatment (43.2%), patient transportation and distance to treatment centres (24.3%),poor socioeconomic status (13.5%), complications during serial casting (13.5%),and (5%) other obstacles.

CONCLUSION: Inspite of Ponseti casting technique becoming a common method to treat clubfoot worldwide, In India there are several physician & patients related factors influencing the outcome. There is lack of awareness programs in media (TV/newspaper), schools and colleges and in public meetings. In our country there is no national health programme for clubfoot deformity, so diagnosis of clubfoot deformity is frequently missed at delivery points like sub centers, PHC, CHC and District hospitals. Poor transportation in remote, hard desert area producing hurdle for weekly serial casting and regular follow up.

KEYWORDS

Club Foot, Ponseti's Technique, Indian Population.

INTRODUCTION

Clubfoot or Congenital Talipes Equino Varus (CTEV) is a common complex congenital deformity of the foot. It is a three-dimensional deformity having four components: Equinus, Varus, Adductus and Cavus[1,2]. Many cases are associated with neuromuscular diseases, chromosomal abnormalities, Mendelian and non Mendelian syndromes and in rare cases with extrinsic causes. The incidence differs in different races[3]. Idiopathic clubfoot affects 1-2children per thousand live birth and is one of the leading causes of disability worldwide. Ponseti's technique of casting, tenotomy and bracing is an acceptable method worldwide in its management[4,5]. However, in this study, only the cases with idiopathic congenital clubfoot deformity are included, occurring in otherwise normal infants.

Ponseti's Technique:

The technique is done in the followingstep[6,7,8].

1. Classifying the child's deformity based on aetiopathology and treatment stage on first presentation.
2. Grading the deformity by Dimeglio's/Pirani's classification system.
3. Patient's family counselling and setting up of club foot clinics.
4. Application of casts in a weekly manner by first putting the foot in supination and then gradually abducting in sequential casts till the navicular covers the talar head completely clinically manifested as 70° of abduction, avoiding eversion or forced dorsiflexion in weeklycasts".
5. Tenotomy, if it is found that tendoachilles is tight ,as without tenotomy we cannot achieve 10° of dorsiflexion.
6. Bracing schedule to be followed till the age of 3 years and follow-up subsequently. Ponseti's technique is presently established only for congenital idiopathic club feet and trials are undergoing for syndromic, neglected and complicated club feet.

The Ponseti method has change the management of idiopathic club foot deformity from a typically surgical approach[12] to a primarily non operative Approach[9,10].

Establishment's or setup's where Ponseti's technique is being practised in India:- Government or Institutional setups; Non Government institutional setups; Private nursing homes and clinics.

AIMS &OBJECTIVES

1. To find out the obstacles during treatment of ctev by Ponseti.
2. Enligten the solutions for obstacles to achieve 100% acceptability for treatment.

RESULTS

Out of the 215patients treated 139 patients (65%) were from a rural background and 76 patients (35%)belonged to urban areas.

Table;1-Distribution of patients according to Area.

Area/Background	No Of Patients	Percentage (%)
Rural	139	65
Urban	76	35
Total	215	

The patients were classified as per Pirani scoring system. In our study 37 (17.2%)patients encountered obstacles in the treatment of ctev. The most frequent obstacles to the Ponseti method in India in our study was lack of awareness of treatment of ctev in the country 16 (43.3%) these patients missed follow-up and serial casting weekly, which led to improper follow up after Correction and incompatibly issues with brace application.

patient transportation and distance to treatment centres 9(24.3%), in our study patients came from rural desert area 60 patients from about 50 km.12 patients from about 100 kms.37 patients from 150 kms,22 patients from 250 kms,8 patients from 300 kms ,Patient transportation and distance to tpeatment centres which led to patient's not returning back till full correction.

Poor socioeconomic status 5 patients (13.5%), these parents cannot afford expenditure of treatment. and complications during serial casting.

5 patients (13.5%) which led to patient's families discontinued the treatment in between or led to complications like skin blisters, incorrect application of plaster Casts. 90% of the parents had attended weekly clinics with 67% indicating that they did not know about clubfoot and its treatment.

Table;2- Obstacles Encountered During Treatment Of Clubfoot by Ponseti method In Western Rajasthan

S.No.	Obstacles Encountered During Treatment Of Clubfoot In Western Rajasthan	No.of patients	Percentage (%)
1.	lack of awareness of treatment of ctev	16	43.3
2.	Patient transportation and distance to treatment centres	9	24.3
3.	Poor socioeconomic status	5	13.5

4.	Complication like skin blisters, incorrect application	5	13.5
5.	Other complication	2	5.4
Total		37	

Factors Influencing the Successful Management at Various Level of Healthcare:-

Patient related- Other forms of club foot management like- parents may seek non ponseti management methods, traditional medicines and other methods. These are ineffective and delay make ponseti treatment more difficult. This problem can be managed with education of family and there health care provider. There is public belief in some culture that clubfoot is caused by evil spirits , due to sins or misdeed of family or parents . The child with disability is a source of shame and is hidden by family .They do not have the benefits of an examination of newborn by trained healthcare workers . They don't have awareness of the diagnosis and the need for early treatment including misinformation that ponseti method is ineffective . These obstacles can be overcome by establishing clubfoot clinic and make ponseti management facility for every clubfoot affected feet . Engage parents to clubfoot clinic and discuss management and follow up to parents ,caregivers, and convey the message of free treatment in the society. Involve local government, panchayat, municipal corporation, schools, meetings, PHC ,CHC ,religious places, NGO to assist the very poor by facilitating transport and spread awareness about complete cure of CTEV patient.

Health institutional- Most of the government setups do not treat children with club foot deformity in a major manner. This is because clubfoot has not received importance at govt level in the centre or state , in spite of being the major presentation .This is the sad reality even under the department of Health and Family Welfare at PHC, CHC and even district hospitals where doctors and nursing staff are not aware about CTEV treatment by ponseti. There is neither any training facility to empower skills in CTEV treatment nor any national health programs for CTEV disbilty . In rajasthan where 75% rural and 60 % area is desert and less institutional delivery, awareness programs are very necessary at each level from beneficiary to health system. There is less number of orthopedic surgeon in the state and orthopaedic surgeons in these setups are busy in population control programs/Trauma or private practice rather than taking care of club foot children. Even most of the medical colleges in the govt setup do not stick to exclusive use of Ponseti's technique inspite of having speciality clinics. Ponseti's technique is used only if a thesis is given to a post-graduate or if a particular consultant is trained in this technique . "Cure" along with govt. has taken initiative in managing these patient's , specially in some states where comprehensive care in the form of training, counselling, models and materials, follow-up record sheets& braces are provided by them . But such scheme is yet limited to largecities and medical colleges.

The patient related barrier are simple to understand. Most of the Govt. set ups including Govt. Medical Colleges cater to the poor people. Poverty, illetracy and distances are the major barrier in managing a club foot child by parents. Parents prefer a one time surgery may be with inferior results rather than travelling long distances every week to get the plaster changed. Also routinely there is no provision to admit children for day-care Ponseti's technique. The need for prolongel bracing is the second barrier in the method. Insuring economic/free supply of bilateral foot dorsiflexion - Abduction brace is almost impossible.

Speciality clinics:- Most of the poor parents discontinue treatment due to lack of awareness. long term brace does not suit the parents & compliance becomes an important issue. Most of the medical colleges, even if they run a speciality clinic of club foot have their day and time fixed and so patient's with club foot won't get round the clock attention, apart from any emergency treatment if complication arises. Ponseti's clinics overcomes these problems to some extent as the parents see the outcome of others who are not following instruction, leading to recurrence of symptoms.

Non govt funded institutes:- They also treat club foot in the ideal way i.e. Ponseti's technique but the cost of treatment becomes tremendous as the consultation fee/plastering fee/plaster material cost/Anaesthetist cost/OT cost for tenotomy and post op. ward even in a day care setting are very high. They also require trained assistants to hold the foot in corrected position or apply the cast. Tenotomy even if it is a minor surgery require the complete pre-operative/intra operative and postoperative protocol in these institutes.

So, parents think that instead of having so many plaster'sand then surgery, why not go for a single one timed surgery which willnot only save money but time as well.

Summary of obstacles in the practice of Ponseti's technique

1. Parents from affluent societies insist to give anaesthesiato that child is not irritable and do not cry during manipulationor cast application. This eventually leads to more complications,edema and poor results.
2. Orthopaedic surgeons are still not very familiar to new terminology, classification systems and Ponseti's technique.
3. The technique does not work if speciality clinic is not initated. Patient counselling is a must.
4. Institutes which do not have full time Orthopaedic Surgeonassist one time correction rather than repeated visits of patint and orthopaedic surgeons.
5. Tenotomy is projected as a major surgery at times.
6. Avoiding tenotomy or bracing is a major cause of recurrence.
7. Poor results are also seen if a wrong selection of case is done & neglected, Complicated or syndromic clubfoot are counselledand treated like idiopathic club foot.
8. Social stigma of CTEV.

Recommendations for overcoming obstacles:-

1. Making the government aware of Ponseti's protocol and taking its help in establishing club foot clinics, where children withclub foot will be treated only by trained and appointed orthopedic surgeons.
2. Provision of post correction basic braces free of cost, whenthe brace is returned after use and reapplied to another child till 3 yrs of age.
3. Provision of well equipped operation theatre with anaesthetino that tenotomy may be done properly with antisepsis and without pain and children with neurological, syndromic and complicted clubfoot be also treated with surgical care. Provision of a post operative ward and shelter for these children and their families.
4. Free transport of these children to and from to the pre identified clinics as to insure attendance and full treatment.
5. Making a national health programs for CTEV patients.
6. Making a training schedule for CTEV treatment and counselling to orthopaedic doctors and assistants.
7. Engage more and more public to CTEV treatment awareness programs via media TV/newspaper, posters in hospital premis, schools ,colleges, awareness programs in community meeting ,and religious places.
8. Involve more NGO for awareness, counselling of CTEV parents.
9. Make a provision to give expenditure to CTEV patients.
10. Make a future policy for CTEV affected children.
11. Arrange a clubfoot clinic in remote desert area.

DISCUSSION

In spite of Ponseti casting technique becoming a common method to treat clubfoot worldwide, in developing countries like India, there are several physician & patients factors influencing the outcome. Skill management in improving Physician and Patient's family factors should be integrated in practise to prevent neglect in treatment .A Programme about proper application of Ponseti technique for doctors and patient's family education can help .

A COMPARATIVE PROSPECTIVE STUDY OF THE RESULTS OF CLOSED REDUCTION AND PERCUTANEOUS KIRSCHNER WIRE FIXATION UNDER IMAGE INTENSIFIER CONTROL OF DISPLACED SUPRACONDYLAR FRACTURE OF HUMERUS IN CHILDREN

Orthopaedics

Dr. Ashok Singhvi Principal Specialist, Dr. S.N. Medical College, Jodhpur

Dr. Hemant Jain* Assistant Professor, Dr. S.N. Medical College, Jodhpur *Corresponding Author

Dr. Nitin Goyal Junior Resident, Dr. S.N. Medical College, Jodhpur

ABSTRACT

INTRODUCTION:- This study was conducted to assess the results of closed reduction and percutaneous kirschner wire fixation under image intensifier control of displaced supracondylar fracture of humerus in Children.

METHOD:- In this prospective study 40 cases with supracondylar humerus fracture treated with closed reduction(25 cases) or fixation with Kirschner wires under image intensifier(15cases) and evaluated clinically and radiologically. The assessment of anatomical and functional outcome was made according to Mitchell and Adams criteria.

RESULT:- In our study 40 cases were studied. The age of patient ranged from 6 to 10 years. Male to female ratio was 4:1.Maximum cases were extension type(95%). The assessment of anatomical and functional outcome was made according to Mitchell and Adams criteria. 5 cases (20%) in closed reduction and 9 cases (60%) in fixation with K wire were rated as excellent, 10 cases (40%) rated as good, 10 cases (40%) was rated as poor in closed reduction and 4 case(26.6%) was rated as good and 2 cases (13.4%)was rated as poor in fixation with k wire.

CONCLUSION:- We concluded that Closed reduction and plaster of paris splinting should be reserved for minimally displaced fractures. Further attempts at closed reduction should be made, as repeated manipulations increasers' incidence of myositis ossifications and residual stiffness.In all other cases, closed reduction and fixation with Kirschner wires under image intensifier control should be attempted

KEYWORDS

Supracondylar of humerus, Kirschner wire, Modified Garland classification, closed reduction.

INTRODUCTION

Supracondylar fractures of humerus constitute 60% of the fractures around elbow in children, thus being the commonest fracture around the elbow in children. The management of displaced supracondylar fractures is controversial, there are no set guidelines as to which reduction is acceptable and which is not. Surgeon treats the fracture according to his personal preference or according to the method prevalent in his Centre.

Two types of the supracondylar fractures of humerus are encountered in children

1. The Extension type : which is more common
2. The flexion type : which is less common

Fall onto the outstretched hand with the elbow in full extension leading to supracondylar fracture of humerus. Laxity of ligaments which allow hyperextension of elbow to occur. Henrikson[1] (1966) had shown that children with supracondylar fractures of humerus are more likely to have hyperextension of normal elbow and also children with hyperextension are more susceptible to repeated supracondylar fractures. The rarer type is the flexion type of fracture. It is caused by the direct fall on the flexed elbow and its distal fragment is displaced anteriorly. Although the extensive literature on this fracture describes several methods of treatment, both conservative and operative , it would appear that none is suitable for all fractures, not has any method gained universal acceptance. Therefore, this fractures has been rightly nick named as the misunderstood fracture by Gartland[2] (1949).

Gartland proposed a useful classification for supracondylar fractures:
Type I : Undisplaced fracture,
Type II : Displaced with intact posterior cortex.
Type III : Displaced with no cortical contact.

Modified Garland classification of supracondylar fracture
Type I : Undisplaced;
Type II : Hinged posteriorly
Type III : Displaced;
Type IV : Displaces into extension and flexion.

Whatever maybe the controversy in treatment, but the ultimate aim is the management of these fractures even today as what Sirs[3] suggested in 1939 are to prevent volkman's ischaemic contracture and malunion, restore function to elbow, achieve satisfactory reduction, thus attaining cosmetically acceptable results.

The impulse for this clinical study of supracondylar fractures of humerus cam chiefly from the fact that almost every day one or more patients with this fracture visited the emergency Plaster Room of this hospital. As compared to the Western countries, articles on this subject by Indian authors are much less. Thus, the field for the study on supracondylar fractures of humerus remains still wide open in the Indian patients.

AIMS and Objectives

1. To study the results of managing displaced supracondylar fractures of humerus of children by using conservative closed reduction methods and percutaneous Kirschner wire fixation under Image Intensifier.
2. If possible to formulate guidelines to select the better method of treatment of displaced supracondylar fractures of humerus in children.
3. To assess the elbow functions after fracture has healed.

Material and methods

Forty cases have been studied; all patients with displaced supracondylar fractures of humerus were admitted in the orthopedic emergency and subjected to detailed clinical and radiological examination according the case Performa.

These patients were subjected to closed manipulation and immobilization by plaster of paris slab, under general anesthesia as early as possible. All the closed reduction was carried out by the method described by Charnley[4] (1961), which is briefly described below.

The patients are anesthetized; the radial pulse is palpated before starting the manipulation. The elbow is gently extended and a strong longitudinal traction exerted by gripping the patients wrist and distal forearm. The distal forearm moves into line by straight longitudinal traction and any lateral displacement is automatically corrected by tension of surrounding soft parts. It lateral displacement has not been overcome; some lateral pressure while the elbow is extended completes the reduction. Now the surgeon grips the lower end of distal humerus in his passive or fixing hand maintaining traction in the long axis of the forearm, the thumb of the passive fixing hand pushes the olecranon forwards as the elbow is flexed. The fingers of the passive had pulls the proximal fragment backwards. The elbow should be hyper flexed (to 120 degree) or to a position where the radial pulse is normal. Now an above elbow plaster of paris slab is applied and the limb is elevated and a close watch is kept on the digital circulation and radial pulse. The patients elbow is immobilized for 3 weeks after which mobilization of the joint started.

ISSN No 2277 - 8179 | IF : 4.176 | IC Value : 93.98

The patients unsatisfactory reductions will be reduced under general anaesthesia. Traction is applied to the forearm in supination, and the shorting and lateral or medial displacements are corrected. Once adequate reduction have been achieved, as confirmed with the image intensifier, then under all aseptic precautions two kirschner wires 1.4 to 1.8 millimeters in diameter are introduced, one through the lateral epicondyle and one through the medial epicondyle. These two kirschner wires are directly obliquely and proximally unit they pass through the opposite side of the cortex. In order to secure sufficient fixation of the fracture, it is imperative that the two wires must pass through the proximal fragment or shaft. The final position of the wires is checked under the image intensifier and if found satisfactory, the protruding parts of the wires are cut off below the skin surface and a plaster splint is applied from the shoulder to the knuckles, with elbow at right angle and the forearm in neutral of pronation supination.

Check x-rays are taken and the limb examined for any postoperative neurological deficit. After three weeks, the plaster slab is removed and elbow mobilization started. The Krischner wires are removed after four weeks under local anaesthesia.

Results obtained were graded according to Mitchell and Adams criteria[2] (1961) and presented. Mitchell and Adams criteria (1961) as given below.

Excellent : Change in carrying angle of less than 5 degree loss of range of motion of less than 10 degree No. symptoms'

Good : Change in carrying angle of 5-15 degree. Loss of range of motion of 10-20 degree. No symptoms.

Poor : Change of carrying angle or reduction of motion above these limits. Any notable symptoms.

RESULTS

DISCUSSION

Supracondylar fractures of humerus as the "misunderstood fracture" because in present problems in management in the form of vascular complications, cosmetically unacceptable deformities and stiff elbows to say the least. Unfortunately no uniform mode of treatment is available which is suited to all grades of fractures, in order to achieve consistently acceptable and a normal functioning elbow.

The maximum incidence of supracondylar fracture in present study was seen in 6-10 years of age group and the average was 7.27 years.

Males out number females in all age groups. The ratio being 4:1 in favour of males. This is a consistent feature in series reported by Holmberg[4] (1945), Maylahn and Fahey[5] (1958) and Henrikson[2] (1966), the fracture being twice more comm on in males than females.

The left side was injured in 27 cases (67.5%) and right side in 13 cases (32.5%) respectively. This agree with the findings of Holmberg[4] (1945), Maylahn and Fahey[5] (1958) and Edman and Lohr[3] (1963).

Flexion type of Supracondylar fracture of humerus is less common than the extension type. In the present study only 2 cases (5%) of flexion type were seen. Incidence in Western literature ranges from 2.5% to 10%.

The Majority of cases were of the closed type (36 cases) in the present series. Four cases of open fracture were seen with all having a punctured wound in the cubital fossa. All four of the fractures healed without any consequences.

Twenty nine cases came to the hospital more than 12 hours after the injury. The parents ignored the child's cry probably due to ignorance till the elbow became swollen and severely painful.

In all patients an initial attempt at closed reduction under general anesthesia was carried out. Subsequently, 25 cases were definitively continued on conservative treatment with plaster of paris splinting and 15 cases by close reduction and Kirschner wires fixation under image intensifier control.

Grading the end results according to Mitchell and Adams' Criteria (1961), we classified the results into two groups (1) Satisfactory [Excellent +Good] and (2) Unsatisfactory [Poor]. We got 40% poor results with closed reduction and plaster of paris splinting and 60% were satisfactory.

Close reduction and fixation with K wires under Image Intensifier gave maximum percentage of excellent results (60%). Closed reduction gave 20% excellent results. Closed reduction and fixation under image intensifier has following main advantages.

1. It makes accurate reduction possible

2. Hospital stay is shortened

The average time taken for gaining elbow motion was more with close reduction and internal fixation with K wire under image intensifier cases. Time taken is more because soft tissues around the elbow are subjected to surgical trauma.

The overall incidence of nerve involvement was 3.92% in the present series, with one case of redial nerve and one of medial nerve involvement. Ulnar nerve involvement was not encountered. Both these cases were treated an expectant lines and both recovered completely within 9 weeks.

The overall incidence of cubitus varus in the present study was 22.5% which compares favorably with the average incidence of 30% given by **Siris[3] (1939), Brewster and Karp[9] (1940), Sandegard[10] (1943), Aikten[11] (1943) and Madsen[12] (1955).** No case of cubitus valgus was seen in the present series.

CONCLUSION

Closed reduction and plaster of paris splinting should be reserved for minimally displaced fractures. Further attempts at closed reduction should be made, as repeated manipulations increasers' incidence of myositis ossifications and residual stiffness.

In all other cases, closed reduction and fixation with Kirschner wires under image intensifier control should be attempted. If it is done as a last resort after repeated manipulation the percentage of poor results increases. Thus, closed reduction and Kirschner wire fixation under image intensifier is advisable for displaced supracondylar fractures of humerus. It should be performed as early as possible (not later than five days) and should not be done when patient has undergone repeated manipulations because of the high incidence of myositis ossifications and stuffiness of elbow postoperatively.

ABSTRACT

INRTODUCTION: Idiopathic clubfoot affects approximately 50,000 children each year and is one of the leading causes of disability in India. Ponseti's technique of casting, tenotomy and bracing is an acceptable method worldwide in its management.

MATERIAL AND METHOD: The Ponseti technique is very slowly picking up in our country, inspite of its ease of usage and compatible results. In this retrospective study of 215 patients enrolled from march 2013 to June 2016. We will be discussing the ponseti's technique in brief, various set-up's where the technique is being adopted and the obstacles faced by parents at each level.

RESULTS: In our study total 37 (17.2%) parents' encountered obstacles. The most frequent obstacles to the Ponseti method in our study are lack of awareness for clubfoot treatment (43.2%), patient transportation and distance to treatment centres (24.3%).poor socioeconomic status (13.5%), complications during serial casting (13.5%),and (5%) other obstacles.

CONCLUSION: Inspite of Ponseti casting technique becoming a common method to treat clubfoot worldwide. In India there are several physician & patients related factors influencing the outcome. There is lack of awareness programs in media (TV/newspaper). schools and colleges and in public meetings. In our country there is no national health programme for clubfoot deformity, so diagnosis of clubfoot deformity is frequently missed at delivery points like sub centers, PHC, CHC and District hospitals. Poor transportation in remote, hard desert area producing hurdle for weekly serial casting and regular follow up.

KEYWORDS

Club Foot, Ponseti's Technique, Indian Population.

INTRODUCTION

Clubfoot or Congenital Talipes Equino Varus (CTEV) is a common complex congenital deformity of the foot. It is a three-dimensional deformity having four components: Equinus, Varus, Adductus and Cavus[1,2]. Many cases are associated with neuromuscular diseases, chromosomal abnormalities, Mendelian and non Mendelian syndromes and in rare cases with extrinsic causes. The incidence differs in different races[3]. Idiopathic clubfoot affects 1-2children per thousand live birth and is one of the leading causes of disability worldwide. Ponseti's technique of casting, tenotomy and bracing is an acceptable method worldwide in its management[4,5]. However, in this study, only the cases with idiopathic congenital clubfoot deformity are included, occurring in otherwise normal infants.

Ponseti's Technique:

The technique is done in the followingstep[6-9].

1. Classifying the child's deformity based on aetiopathology and treatment stage on first presentation.
2. Grading the deformity by Dimeglio's/Pirani's classification system.
3. Patient's family counselling and setting up of club foot clinics.
4. Application of casts in a weekly manner by first putting the foot in supination and then gradually abducting in sequential casts till the navicular covers the talar head completely clinically manifested as 70° of abduction, avoiding eversion or forced dorsiflexion in weeklycasts[11].
5. Tenotomy, if it is found that tendoachilles is tight ,as without tenotomy we cannot achieve 10° of dorsiflexion.
6. Bracing schedule to be followed till the age of 3 years and follow-up subsequently. Ponseti's technique is presently established only for congenital idiopathic club feet and trials are undergoing for syndromic, neglected and complicated club feet.

The Ponseti method has change the management of idiopathic club foot deformity from a typically surgical approach[12] to a primarily non operative Approach[13,14].

Establishment's or setup's where Ponseti's technique is being practised in India:- Government or Institutional setups; Non Government institutional setups; Private nursing homes and clinics.

AIMS &OBJECTIVES

1. To find out the obstacles during treatment of ctev by Ponseti.
2. Enligten the solutions for obstacles to achieve 100% acceptability for treatment.

RESULTS

Out of the 215patients treated 139 patients (65%) were from a rural background and 76 patients (35%)belonged to urban areas.

Table;1-Distribution of patients according to Area.

Area/Background	No Of Patients	Percentage (%)
Rural	139	65
Urban	76	35
Total	215	

The patients were classified as per Pirani scoring system. In our study 37 (17.2%)patients encountered obstacles in the treatment of ctev. The most frequent obstacles to the Ponseti method in India in our study was lack of awareness of treatment of ctev in the country 16 (43.3%) these patients missed follow-up and serial casting weekly, which led to improper follow up after Correction and incompatibly issues with brace application.

patient transportation and distance to treatment centres 9(24.3%). in our study patients came from rural desert area 60 patients from about 50 km,12 patients from about 100 kms,37 patients from 150 kms,22 patients from 250 kms,8 patients from 300 kms ,Patient transportation and distance to treatment centres which led to patient's not returning back till full correction.

Poor socioeconomic status 5 patients (13.5%), these parents cannot afford expenditure of treatment. and complications during serial casting.

5 patients (13.5%) which led to patient's families discontinued the treatment in between or led to complications like skin blisters, incorrect application of plaster Casts. 90% of the parents had attended weekly clinics with 67% indicating that they did not know about clubfoot and its treatment.

Table;2- Obstacles Encountered During Treatment Of Clubfoot by Ponseti method In Western Rajasthan

S.No.	Obstacles Encountered During Treatment Of Clubfoot In Western Rajasthan	No of patients	Percentage (%)
1.	lack of awareness of treatment of ctev	16	43.3
2.	Patient transportation and distance to treatment centres	9	24.3
3.	Poor socioeconomic status	5	13.5

4.	Complication like skin blisters, incorrect application	5	13.5
5.	Other complication	2	5.4
Total		37	

Factors Influencing the Successful Management at Various Level of Healthcare:-

Patient related- Other forms of club foot management like- parents may seek non ponseti management methods, traditional medicines and other methods. These are ineffective and delay make ponseti treatment more difficult. This problem can be managed with education of family and there health care provider. There is public belief in some culture that clubfoot is caused by evil spirits , due to sins or misdeed of family or parents . The child with disability is a source of shame and is hidden by family .They do not have the benefits of an examination of newborn by trained healthcare workers . They don't have awareness of the diagnosis and the need for early treatment including misinformation that ponseti method is ineffective . These obstacles can be overcome by establishing clubfoot clinic and make ponseti management facility for every clubfoot affected feet . Engage parents to clubfoot clinic and discuss management and follow up to parents ,caregivers, and convey the message of free treatment in the society. Involve local government, panchayat, municipal corporation, schools, meetings, PHC ,CHC ,religious places, NGO to assist the very poor by facilitating transport and spread awareness about complete cure of CTEV patient.

Health institutional- Most of the government setups do not treat children with club foot deformity in a major manner. This is because clubfoot has not received importance at govt level in the centre or state , in spite of being the major presentation .This is the sad reality even under the department of Health and Family Welfare at PHC, CHC and even district hospitals where doctors and nursing staff are not aware about CTEV treatment by ponseti. There is neither any training facility to empower skills in CTEV treatment nor any national health programs for CTEV disbilty . In rajasthan where 75% rural and 60 % area is desert and less institutional delivery, awareness programs are very necessary at each level from beneficiary to health system . There is less number of orthopedic surgeon in the state and orthopaedic surgeons in these setups are busy in population control programs/Trauma or private practice rather than taking care of club foot children. Even most of the medical colleges in the govt setup do not stick to exclusive use of Ponseti's technique inspite of having speciality clinics. Ponseti's technique is used only if a thesis is given to a post-graduate or if a particular consultant is trained in this technique . "Cure" along with govt. has taken initiative in managing these patient's , specially in some states where comprehensive care in the form of training, counselling, models and materials, follow-up record sheets& braces are provided by them . But such scheme is yet limited to large cities and medical colleges.

The patient related barrier are simple to understand. Most of the Govt. set ups including Govt. Medical Colleges cater to the poor people. Poverty, illetracy and distances are the major barrier in managing a club foot child by parents. Parents prefer a one time surgery may be with inferior results rather than travelling long distances everyweek to get the plaster changed. Also routinely there is no provision to admit children for day-care Ponseti's technique. The need for prolonged bracing is the second barrier in the method. Insuring economic/free supply of bilateral foot dorsiflexion - Abduction brace is almost impossible.

Speciality clinics:- Most of the poor parents discontinue treatment due to lack of awareness. long term brace does not suit the parents & compliance becomes an important issue. Most of the medical colleges, even if they run a speciality clinic of club foot have their day and time fixed and so patient's with club foot won't get round the clock attention, apart from any emergency treatment if complication arises. Ponseti's clinics overcomes these problems to some extent as the parents see the outcome of others who are not following instruction, leading to recurrence of symptoms.

Non govt funded institutes:- They also treat club foot in the ideal way i.e. Ponseti's technique but the cost of treatment becomes tremendous as the consultation fee/plastering fee/plaster material cost/Anaesthetist cost/OT cost for tenotomy and post op. ward even in a day care setting are very high. They also require trained assistants to hold the foot in corrected position or apply the cast. Tenotomy even if it is a minor surgery require the complete pre-operative/Intra operative and postoperative protocol in these institutes.

So, parents think that instead of having so many plaster and then surgery, why not go for a single one timed surgery which will not only save money but time as well.

Summary of obstacles in the practice of Ponseti's technique

1. Parents from affluent societies insist to give anaesthesia so that child is not irritable and do not cry during manipulation or cast application. This eventually leads to more complications oedema and poor results.
2. Orthopaedic surgeons are still not very familiar to new terminology, classification systems and Ponseti's technique.
3. The technique does not work if speciality clinic is not affiliated. Patient counselling is a must.
4. Institutes which do not have full time Orthopaedic Surgeon insist one time correction rather than repeated visits of patient and orthopaedic surgeons.
5. Tenotomy is projected as a major surgery at times.
6. Avoiding tenotomy or bracing is a major cause of recurrence.
7. Poor results are also seen if a wrong selection of case is done & neglected, Complicated or syndromic clubfoot are counselled and treated like idiopathic club foot.
8. Social stigma of CTEV.

Recommendations for overcoming obstacles:-

1. Making the government aware of Ponseti's protocol and taking its help in establishing club foot clinics, where children with club foot will be treated only by trained and appointed orthopedic surgeons .
2. Provision of post correction basic braces free of cost, when the brace is returned after use and reapplied to another child till 3 years of age.
3. Provision of well equipped operation theatre with anaesthetist so that tenotomy may be done properly with antisepsis and without pain and children with neurological, syndromic and complicated clubfoot be also treated with surgical care. Provision of a post operative ward and shelter for these children and their families.
4. Free transport of these children to and from to the pre identified clinics as to insure attendance and full treatment.
5. Making a national health programs for CTEV patients.
6. Making a training schedule for CTEV treatment and counseling to orthopaedic doctors and assistants.
7. Engage more and more public to CTEV treatment awareness programs via media TV/newspaper, posters in hospital premise, schools ,colleges, awareness programs in community meetings ,and religious places.
8. Involve more NGO for awareness, counselling of CTEV parents.
9. Make a provision to give expenditure to CTEV patients.
10. Make a future policy for CTEV affected children.
11. Arrange a clubfoot clinic in remote desert area.

DISCUSSION

In spite of Ponseti casting technique becoming a common method to treat clubfoot worldwide, in developing countries like India, there are several physician & patients factors influencing the outcome. Skill management in improving Physician and Patient's family factors should be integrated in practise to prevent neglect in treatment .A Programme about proper application of Ponseti technique for doctors and patient's family education can help .

Segmental tibial fractures treated with unreamed interlocking nail – A prospective study

Ashok Singhvi, Hemant Jain, Siddharth Jauhar, Kishore Raichandani

DOI: http://dx.doi.org/10.22271/ortho.2017.v3.i2h.73

Abstract
Introduction: Fractures of tibia are common and major skeletal injuries. Treatment of such fractures in adults is a challenge to orthopaedic surgeons due to its poor soft tissue coverage and poor blood supply. The aim towards treatment for the segmental fracture tibia is union maintaining normal length, normal alignment without rotational deformity, normal joint movements and reduced hospital stay.
Method: In our department since 2012 to 2014, 51 segmental tibia fractures were treated with unreamed interlocking intramedullary nailing technique with one proximal and one distal locking screws. Postoperatively, early mobilization exercises and weight-bearing were begun. The functional results were assessed by measuring union period and knee range of movements at 6 months.
Results: Fracture healing was obtained in 49(96%) cases within the expected time period. 2(3.2%) patients had non union between proximal and middle segment. 46 (90%) were anatomic (valgus/varus<5^0). 5(9.8%) patients had malunion with valgus more than 5^0. Average range of movement observed at 4 months was 125^0 (70^0-140^0). Superficial infections were noted in 2 patients with compound fracture effectively treated with antibiotics.
Discussion and Conclusion: We conclude that unreamed interlocking nail fixation in segmental tibial fractures seems to be less time consuming, preserves blood supply, relatively simple and good method of treatment with good functional outcome and patient satisfaction provided proper selection of fractures done.

Keywords: Segmental tibial fractures, interlocking nail, poor blood supply, major skeletal injuries

Introduction

Fractures of tibia are common and major skeletal injuries mostly associated with high velocity trauma and often accompanied by substantial damage of the surrounding soft tissue. Treatment of such fractures in adults is a challenge to orthopaedic surgeons due to its poor soft tissue coverage and poor blood supply. The aim towards treatment for the segmental fracture tibia is union maintaining normal length, normal alignment without rotational deformity, normal joint movements and reduced hospital stay. The present study has been taken to review the result of segmental fractures of tibia treated with unreamed intramedullary interlocking nailing.

Material and Methods

This study was conducted between June 2012 to May 2014in the Department of Orthopaedics, Dr. S.N. Medical College and Associated Group of Hospitals, Jodhpur, Rajasthan. 51 patients were admitted in the Department of Orthopaedics with either open (37) or close segmental tibia fractures (14) and treated with interlocking nail. All patients were subjected to a detailed history and clinical examination with particular emphasis on mode of injury, time of injury, interval between injury and hospital admission and nature of treatment taken prior to admission. Clinical examination was including general, systemic, neurovascular and local examination of injured part. Depending on nature of injury relevant radiological examination was done.

Anterior posterior and lateral radiograph were done to diagnose fracture type. Routine preoperative investigation was done.

Open fractures were immediately irrigated, washed and temporarily immobilized with posterior POP above knee slab. Patient was operated within 48 hours of hospital admission.

Inclusion Criteria

- All skeletally mature patients.
- Open segmental tibial fractures (grade I to grade II Gustilo Aderson type)
- Close segmental tibial fractures without soft tissue involvement.

Isometric quadriceps exercise and toes mobilization was started from second postoperative day. Regular weekly follow up was done to inspect wound condition and other complication for compound fractures and regular 2 week follow up for close fractures.

- Passive knee mobilization exercise was started when pain and swelling subside. Active range of motion (ROM) exercise was started after 3 days postoperatively in all patients. Serial radiographs were taken at 4 week interval. Partial weight bearing was started after 21 days, Non weight bearing walking with the help of a walker started after 3 to 5 days and full weight bearing was started after 6 to 8 weeks depending upon the radiological appearance. Patients were followed up periodically on an outpatient basis on 2nd, 4th, 6th, 10th, 14th, 18th week and 6th month. Clinical and radiological assessment will be done for pain, deformity, shortening, range of motion of knee, ankle, subtalar joints and radiological union. final outcome will be assessed using Johner and Wruh's criteria.

Johner and Wruh's criteria [5] for evaluation of final results.

Sl no.	Criteria	Excellent	Good	Fair	Poor
1.	Non-union, infection, Amputations	None	None	None	Yes

Results

In our series maximum numbers of patients (78.42 %) were in age group 21 to 50 years, with age ranging from 18 to 76 years. The mean age of patients under study was 40.6 years. Male: female ratio of our series was 3.25:1, with males being involved almost three and a half times more than females. In our series, 38 cases were open segmental fractures of tibia and 8 cases were closed fractures with compromised soft tissue. Road traffic accident was the most common mode of injury in 44 cases (86.27 %), fall from height in 5 cases and assault in 2 cases. Right leg was involved in 32 cases, left knee in 19 cases. Most common associated injury was clavicle fractures in 10 cases. Other associated injuries seen were [Figure 1].The mean interval between injury and surgery was 1.5 (range, 1–2) days. Primary treatment elsewhere (n=6) was the most common cause of delay in surgery. Six patients required blood transfusion due to open injuries or simultaneous fractures of other bones. The mean hospital stay was 9.5 (range, 5–19) days. The mean interval between surgery and clinical union was 18.2 (range, 14–23) weeks. The mean follow-up period was 10 (range, 10-30) months.

Postoperative complications were observed as in [Figure 2].

Out of 51 cases, 48 had normal leg extension. 3 cases had extensor lag < 10^0 while no cases had > 10^0 extensor lag.

In our series out of 51 cases, 42 cases had either full or more than 140^0 range of motion, 8 had range of motion between 120^0 to 140^0, 1 case had range of motion between 90^0 to 120^0.All patients had range of motion more than 90^0 (acceptable).

No angulation was present in 45 cases. Angulation < than 10^0 was present in 5 cases, angulation in between 10^0 to 20^0 was present in 1 case.

According to johner and wruth's criteria results seen were as shown in [Table 1].

Discussion

The commonest cause of the fracture being high velocity road traffic accidents. In our series 86.27% of the fractures groups were due to high velocity road traffic accidents.

Most of the authors used reamed interlocking nails viz. Olerud and Karlstrom (1972), Puno ét ál (1986), Klemn and Borner (1986), Ekelandét ál (1993) and Renner et ál (1993)[9-11] used undreamed tibial nail while Court-Brown ét al (1990)[12-15] did a comparative study of reamed and unreamed nails. "Reaming resulted in the destruction of all vessels of the medullary canal, rigid nailing with reaming leads to a higher incidence of infection as dead bone produced due to reaming (debris/endosteal necrosis) acts as a good culture medium for bacteria (Bintcliffe *et al.* 1984) [16, 17]. while medullary nail without reaming caused minor damage to the blood supply. Court Brown CM *et al.* (1996) [12-15] made a prospective study in 50 cases and concluded that reamed is better than unreamed nailing in tibial closed fractures. Larsen *et al.* (2004) studied 45 patients and concluded that the average time to fracture healing was 16.7 weeks in reamed group and 25.7 weeks in the unreamed group. The difference was significant (P=0.004). Mohit Bhandari *et al.* (2008) [18] conducted a multicenter, blinded randomized trial of 1319 adults in whom a tibial shaft fracture was treated with either reamed or undreamed intramedullary nailing and demonstrated a possible benefit for reamed intramedullary nailing in patients with closed fractures. They found necrosis of the inner 50-70% of the cortex after reaming. In our study we used unreamed nail in 38 patients and reaming only in proximal segment (To make high and anterior entry which prevents anterior projection of small proximal fragment due to pull of

patellar tendon) in remaining 13 patients.

In our study 74.51% patients were having open injury, this is in agreement with the study shown by Woll and Duwelius [19] who have reported an incidence of 75% open fractures in this pattern of injury.

Many authors support and recommend fixation with intramedullary nailing [35] with advent of interlocking nail provide superior results [12, 13]

Similar to our study and observations Ekeland and Alho [20, 21] examined 43 patients with segmental tibial fractures out of which they reported one non union, one deep and one superficial infection and finally they concluded that the interlocking nail proved to be efficient mode of treatment for comminuted segmental and unstable tibial fractures.

In our series 2 patients (3.9%) had superficial wound infection of the proximal incision site. This responded to the usual oral antibiotics and daily dressings. One patient (1.96%) had deep infection. Regular dressing, oral antibiotics and guarded weight bearing was continued till the fracture united (18 weeks). two cases had superficial infection were Gustilo's grade II. The injury surgery interval in one of these cases was 7days and the other 2 were 4-5 days (because of associated head injury). This delay in the surgery was the probable cause of superficial infection in two cases and deep infection in one case. This indicates that early surgery with a proper antibiotics cover is a must when considering a case of compound tibial fracture for nailing.

We encountered 3 cases of delayed union in which, after waiting for about 16 weeks when abundant callus was not visible in the skiagram and the patient had persistent tenderness over the fracture site. Two of the cases had hypertrophic type of non-union. The reason in one of these cases was probably a deep infection due to improper hygiene and non -compliance of the patient to follow the weight bearing protocol and other instructions and also lack of regular antibiotic intake. This indicates the importance of regular follow up and patients compliance.

The distal fracture is the usual site for the non-union, proposed reason for this being the direct injury to the soft tissue overlying this fracture and natural tendency to slow union in fractures at this location [22].

Although other authors reported no significant difference in union rate at proximal and distal fracture sites. this is consistent with our results as in our study we got non- union in two patients at proximal fracture site.

Most common postoperative complication was anterior knee pain in 5 patients. Occasional Pain in knee was a common problem in 32 patients, 5 patients had constant pain after activity. However the pain did not disturb the activities of daily living in majority of patients.

In our series out of 51 cases 47 (92.15%) had acceptable Johner and wruth's criteria for functional results (sum of excellent and good results). Excellent in 36 (70.59%), good in 11 (21.57%), fair in 3 (5.87%) and poor in 1 (1.97) Ekeland and Alho [20, 21] reported results excellent in 29, good in 13 and fair in 2 and poor in one out of 45 cases.

Conclusion

From the observation of present study it is concluded that the high-energy trauma associated with this pattern of injury poses many challenges to the surgeon due to the precarious blood supply of the intermediate segment and the serious damage to the surrounding soft tissues. The risk of non-union, delayed union, infection and additional procedures is high as seen in this series of patients. The preferred method of initial fracture stabilisation is the use of unreamed interlocking intramedullary tibial nail with immediate soft tissue cover whenever possible, this procedure require less surgical time, hospital stay, is cost effective and have minimum complications with good functional outcome.

Conclusions: *This study disclosed that maintaining anatomical reduction is key stone for satisfactory outcome. Best functional results were achieved till 6 months of treatment.*

Keywords: *Barton's fracture, Orthopedics, anatomical reduction*

INTRODUCTION

It well known that Barton's fractures is named after the American surgeon John Rhea Barton, who first described it in 1838. It is a fracture of the distal end of the radius which involves the articular surface.[1] This fracture can be either an anterior marginal or posterior marginal fractura. These fractures may occur due to low energy or high energy injuries. High energy injuries are more frequent cause of volar Barton's fracture.[2-5] Volar Barton's fractures are different from other distal radius fractures. There is an associated radio carpal dislocation in Barton's fracture. In these type of fractures, conservative treatment is usually unsuccessful. Whereas, in other distal radius fractures, the functional outcome with conservative treatment is good. Complications like loss of reduction, malunion, nonunion, deformity, subluxation and instability are also associated with these types of fractures.[6-8] Several surgical treatment methods are reported in literature. Open reduction and internal fixation with a volar plate system have displayed good results. The main advantages of this system are reduction of articular surface and achieves immediate stability of joint leading to early mobilization of wrist and potential reduction of wrist and finger stiffness and reduction of early onset of wrist osteoarthritis.[9-11]

Fractures of the distal radius found the most common skeletal injuries. It is treated by Orthopaedic surgeons. These

injuries are responsible for one sixth of all fractures assessed in emergency room. The fractures of distal end radius comprise nearly 10-12% of skeletal trauma. These fractures occur due to the fall on out-stretched hand or road traffic accidents. Malunion is the most common complication. It leads to deformity, decreased range of motion at wrist and hand, decreased grip strength due to arthritis.[12] Excellent surgical handling of bone and soft tissues with early post-operative mobilization, help the functional outcome.[13,14] Dislocation of the radiocarpal joint is generally present in intra-articular fractures involving the dorsal or volar rim of the radius. Barton described the fractures of the dorsal rim of radius, that is why it is referred as volar Barton's fracture.[15] This fracture is also categorized as Type 23 B3 in Muller AO classification. Several surgical techniques have been published in literature.[16,17] But the present treatment of choice is ORIF with volar plating. The stability attained with volar plate facilitates in maintenance of reduction and allows early mobilization.[18,19]

METHODS

Study population:- 90 total number of cases were included in this study who attended the OPD.

Study area:- This study was conducted in Department of Orthopedics.

Data collection:- Study included 30 cases of volar Barton fractures treated with buttress plate and screws. Only Fernandez type II (intraarticular fracture produced by shearing) was considered.

Data analysis:- Data were analyzed by using Microsoft excel.

RESULTS

In our study we were included total 90 cases of 0-60 age group. Among all 36 cases were belongs to 41-50 age group followed by 21-30 (27),31-40 (18), & 51-60 (9) age group. We observed that dominant side involvement in 72 cases while non-dominant side involvement was in 18 cases. Mode of injury we were seen Fall on outstretched hand in 63 cases and Road traffic accident in rest cases. This study revealed that subject & functional result which were excellent in 18 & 27, good in 48 & 45 cases, fair in 15 & 6 cases, poor in 9& 12 cases respectively.

DISCUSSION

In the present study 90 patients were included. They belonged to age group of 21 to 70 years with average age of 45 years. Results showed that distal end radius fractures occurred maximum in the age group of 41-50 years i.e. 40%. The main reason behind young population get these fractures more is increasing incidence of motor vehicle accidents which is most common mode of injury in this group. Our findings also revealed that males were predominant i.e. 90% whereas females were only 10%. This could be explained by the fact that males are more commonly involved in road traffic accidents. Similar results were found by King RE.[20]

It is also observed that 80% of patients were having right side involvement. The prevalence of right side was due to the fact that right hand was dominant in all cases. Other studies such as Donald et al. (1982), James (1991) also found the similar results.

In this study all fractures were reduced and fixed anatomically. The union rate was 100%. The fracture healing process is not hindered due to the cancellous bone character. So, the success rate is high. Only the 12 out of 90 patients showed restriction of range of movement due to slight finger contraction that were labeled as fair result. These findings are supported by the study of Kapoor and co-workers (2000). Postoperatively, median nerve function was not affected in any case in the present study. also found the similar findings. Thus, this study suggests that the release of the median nerve is not necessary in ORIF of volar Barton's fractures. Volar plate fixation of unstable distal fractures has been described recently in literature. Results of the present study are similar to the radiological evaluation and functional assessments presented in recent reports.

In the present study, patients were suffered from rupture of the flexor pollicis longus tendon. Drobetz and Kutscha-Lissberg reported that if fracture instability demands distal placement of hardware, close follow-up investigations and hardware removal should be considered at the first sign of flexor tendon irritation. This was also an important point for

Though, T-buttress plate is useful for achieving anatomical reduction, but care must be taken to avoid the complication of tendon rupture. The findings of this study showed that the scores of 27 patients were excellent, 45 patients good, and 12 patients fair.

CONCLUSION

This study analyzed 90 cases of volar Barton fracture operated by various surgeons. It can conclude that most common mode of injury was fall on outstretched hand. Anatomical and functional results were satisfactory in 80% cases fair in 13.3% cases and 6.6% cases had poor result. Complications were observed in 20% cases. Maintaining anatomical reduction is key stone for satisfactory outcome. Best functional results were achieved till 6 months of treatment.

Background: Generally, testis is partly covered by tunica vaginalis derived from processus vaginalis in anterior part. If testis, epididymis and distal part of spermatic cord is covered by tunica-vaginalis, torsion of the testis may occur in this serosal space. The major differential diagnoses are acute epididymitis, strangulated hernia, hematocle, hydrocle, testis tumor and idiopathic scrotal edema
Methods: This prospective study was carried out among 100 male patients between the age group of 14 to 70 years. Around 100 cases were included in our study.
Results: We observed that swelling & pain seen in every cases while fever in 48 cases, burning micturition in 30 cases, abdominal pain in 16 cases & 12 cases of trauma. All the patients treated conservatively responded well with complete recovery.
Conclusions: Our study revealed that Conservative treatment in the form of rest, scrotal support, antibiotics and analgesics is effective in cases of epididymo orchitis and idiopathic scrotal edema.

Keywords: epididymo orchitis, Conservative treatment, tunica vaginalis

INTRODUCTION

The term acute scrotum can be defined as signs and symptoms associated with local inflammation of the scrotum that appear suddenly and generally are not associated with trauma. These signs and symptoms are scrotal pain, swelling, redness and heat.[1] In other words, acute scrotum is an acute painful swelling of the scrotum or its contents accompanied by local signs and general symptoms. In children, the most common causes of acute scrotum are testicular torsion, appendix testis torsion, epididymitis, orchitis and pyocele.[2]

Spermatic cord or torsion of testis is certainly the most serious condition. It affects the scrotum[2] that requires urgent diagnosis and treatment to save the testis and avoid testicular loss, fertility problems and medicolegal issues.[1]

Testicular loss commences past twelve hours of initiation of symptoms. Testicular loss will definitely happen beyond twenty-four hours of symptoms. That is why in the absence of ancillary studies surgeons immediately explore the acute scrotum.[1]

Torsion of testis contains almost 15-40% of all acute testicular pain. This condition depends on abnormal relation of testis to scrotal tissue coverage.

Testicular scan and color doppler ultrasound are the two most commonly used preoperative studies. Testicular scans reliably reveal whether the testes have vascular flow or not but are difficult to be obtained during the night. Doppler ultrasounds are operator dependent and when done by

experienced physician, can reduce the number of emergency operations and hospitalization days.

Generally, testis is partly covered by tunica vaginalis derived from procesus vaginalis in anterior part. If testis, epididymis and distal part of spermatic cord is covered by tunica-vaginalis, torsion of the testis may occur in this serosal space.[2] The major differential diagnoses are acute epididymitis, strangulated hernia, hematocle, hydrocle, testis tumor and idiopathic scrotal edema.[3]

Clinical judgment by the surgeon is undoubtedly the most important factor in assessing testicular salvage. In case of doubt the next step is immediate surgical scrotal exploration. Exact diagnosis of testicular torsion mostly can be confirmed by prompt scrotal exploration. Prognosis is essential when detorsion of the affected testis is performed within first 6 hours.[4]

Even with all the investigations, mostly availab'e only in a few centers in India. Early scrotal exploration remains to be the main stay for diagnosis as well as a therapeutic modality.

METHODS

Study Population:- Total 100 cases were included in this study.

Study Area:-This study was conducted in Department of Surgery.

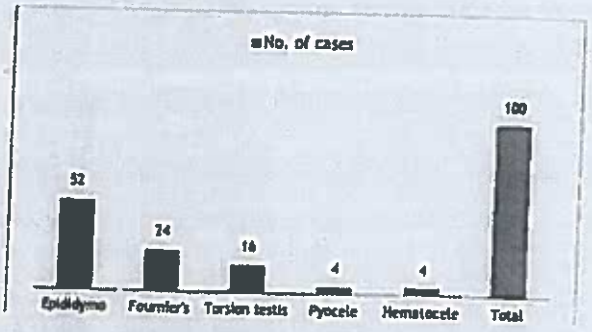
Data collection:- This prospective study among 100 male patients between the age group of 14 to 70 years who visited the surgical outpatient with a history of acute scrotal pain and/or swelling.

Data analysis:- Data were analysed by using Microsoft excel.

RESULTS

In our study we were included total 100 cases. Among all cases, 52 cases of epididymoorchitis followed by Fournier's Gangrene (24 cases), torsion testis (16 cases),4 cases of pyocele & hematocele were found. Out of 100 cases 44 cases of 31-40 age group ,22 cases of 21-30 cases, 12 cases of 41-50 cases,10 cases of 51-60 cases, 8 cases of 11-20 age group & 4 cases of 61-70 age group.

We observed that swelling & pain seen in every case while fever in 48 cases, burning micturition in 30 cases, abdominal pain in 16 cases & 12 cases of trauma. All the patients treated conservatively responded well with complete recovery. In surgically treated patients, post-operative recovery was uneventful in 18 cases with 6 cases developing wound infection as a complication. Average stay in the hospital was 6.27 days in patients with conservative management, 6.39 days in cases of torsion testis and 23.19 days in cases of Fournier's gangrene.



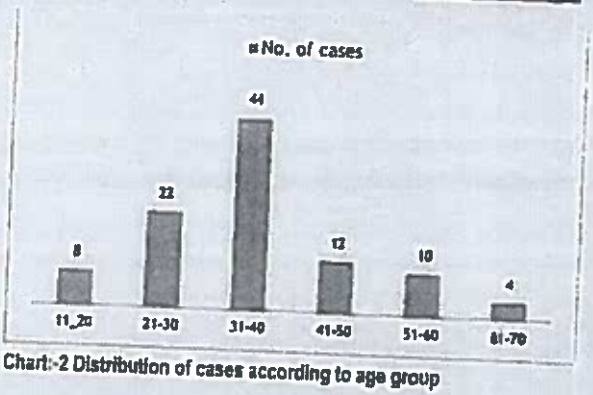


Chart:-2 Distribution of cases according to age group

Table 1: Distribution of cases according to symptoms

Symptoms	No. of cases
Swelling	100
Pain	100
Fever	48
Burning micturition	30
Trauma	12
Pain abdomen	16
Pus discharge from scrotum	10

Treatment	No. of cases
Conservative	52
Incision and drainage	4
Scrotal exploration and drainage	12
Debridement	12
Orchidopexy	10
Orchidectomy	6
Evacuation of hematocele	4

DISCUSSION

Acute scrotum is common among younger individuals with a maximum incidence. It is also common in people who are involved in strenuous work. Trauma and urinary symptoms have a significant effect on the disease. Scrotal swelling with pain is the most common presenting feature which may or may not be associated with fever and burning micturition.

Color Doppler ultrasound is useful tool for evaluating testicular perfusion. Gray scale ultrasound helps to assess the cystic or solid nature of scrotal mass. It often the signs of an inflamed epididymis and a necrotic testicle. In the settings of torsion, a normal homogenous echo pattern shows viable testis whereas a hypo echoic or non-homogenous testis is likely to be non-viable. Ultrasound of the scrotum is extremely sensitive in the diagnosis of acute scrotum with blood investigations and urine analysis being supportive.

Due to the anatomic location and mobility of the scrotum,

right testis is injured more often than the left one. The reason could be its greater propensity to be trapped against the pubis or inner thigh.[5] Testicular rupture is a tears in the tunica albuginea resulting in extrusion of the testicular contents. Speedy surgical intervention is crucial. Ruptured testis can be salvaged, if surgical repair is performed within 72 hours of testicular injury.[5] In the present study, mean time between surgery and the initial trauma was 35 hours. Sports injuries were the most common causes of significant testicular injury. All testes were salvaged, though two boys developed testicular atrophy during follow up. In the diagnosis of testis torsion, standard and Doppler ultrasound accomplishes specificity of 80%-100%.[6] Acute phase proteins can be helpful in the differentiation of acute epididymitis from other non-inflammatory causes of acute scrotum.[6] Even with mentioned diagnostic procedures, sometimes it is not possible to distinguish between TT or some other conditions that mimics clinical presentation of TT. Hence, a surgical intervention is actually a diagnostic procedure. It is always justified in any dilemma for the accuracy of diagnosis. Previously, it has been shown that there is a positive correlation between low air temperature and TT.[7-9]

In this study, TT also most commonly occurred in January. A number of boys underwent surgery in winter and summer, and the lowest number in autumn. The reason could be the relative contraction of cremasteric muscle in winter and increased physical activity in summer, mainly water sports.

CONCLUSION

It can be concluded that Conservative treatment in the form of rest, scrotal support, antibiotics and analgesics is effective in cases of epididymo orchitis and idiopathic scrotal edema. Emergency surgical exploration is beneficial in cases of torsion testis and Fournier's gangrene. Follow up of the patients is essential to find out the complications in form of sterility, development of fistulae and involvement of contralateral side at a later period.

ABSTRACT

Background: *The postoperative wound infection varies from 1 to 9 percent, depending on the surgical procedure. Due to postoperative wound infection, the length of stay in hospital increases. It also increases the cost of the procedure and is associated with significant morbidity. Staphylococcus aureus is the causative agent in 15 to 30% of these infections, though the pathogen isolated differs according to the surgical site.*

Methods: *The population of study was 200. Among 200 cases 29 cases got bacterial infection. This study was conducted in Department of surgery and the patients were recruited on the basis of inclusion and exclusion criteria.*

Results: *In this study we were included total 200 cases. We found that 78 cases of clean wound followed by clean contaminated 54, contaminated 38 & 30dirty wound. Prevalence of infection was 14.5%.*

Conclusion: *Post-operative wound infections are a serious medical problem that has to be tackled due to its increased morbidity, mortality and medical care costs. An active surveillance program is recommended.*

Keywords: *Post –operative wound, Contaminated wound, Organism*

INTRODUCTION

It has been reported by World Health Organization (WHO) that hospital acquired infections to be one of the major infectious diseases having an enormous economic impact worldwide.[1] It is estimated that such infections affect around 2 million people annually resulting in 5% to 15% of them requiring hospitalization.[2]

The postoperative wound infection varies from 1 to 9 percent, depending on the surgical procedure. Due to postoperative wound infection, the length of stay in hospital increases. It also increase the cost of the procedure and is associated with significant morbidity.[3] Staphylococcus aureus is the causative agent in 15 to 20% of these infections, though the pathogen isolated differs according to the surgical site.[4] Risk factors which may responsible for acquiring an infection can be divided into host factors, surgical and environmental factors, and microbial characteristics. Host factors which may contribute to an increased risk of infection are age, prolonged pre-operative length of stay, and concurrent infection at another body site. Increased infection risk may cause an extended surgical procedure. The wound classification, the use of a razor for hair removal before surgery may also be dependent on the surgeon's technical skill.[5]

Even with advances in operative techniques and a better understanding of the pathogenesis of wound infection and wound healing, surgical site infections continue to be a major cause of morbidity and mortality for patients undergoing operative procedures. It is reported that incidence of wound sepsis in India is from 10%-33%. Though, the incidence of wound complications in the obstetric population fluctuates with rates ranging from 2.8% to 26.6%. 1-3 Surgical site infection (S.S.I.) is a valuable tool to demonstrate the magnitude of the problem.

On the basis of the above discussion, the present study was undertaken for early recognition of the problem so that early intervention can be done for better management of postoperative would infections.

METHODS

Study Population:- The population of study was 200.Among 200 cases 29 cases got bacterial infection.

Study Area:- This study was conducted in Department of surgery.

Data collection:- The operative wound was inspected at frequent intervals for clinical evidence of infection. When infection was suspected, three swabs were taken by using sterile cotton swab sticks. One swab was placed in a sterile tube containing Stuart's transport medium for isolation of anaerobic organisms. The second swab was used for Gram staining and the third inoculated on plates of Nutrient agar, Blood agar and McConkey's agar respectively. Swabs in Stuart's medium were inoculated on blood agar plate containing Gentamicin and incubated in MacIntosh Fildes jar using palladized asbestos catalyst, for 48 hours by evacuation and replacement with 90% hydrogen and 10% carbon dioxide.

Data analysis:-Data were analysed by using Microsoft excel.

RESULTS

In this study we were included total 200 cases. We found that 78 cases of ,clean, wound followed by ,clean contaminated 54, contaminated 38 & 30dirty wound. We had done 43 Lower segment caesarean section,14 Hysterectomy,25 ENT surgeries, 25 Plastic Surgeries,25 Orthopedic surgeries, 16 Bowel surgeries, 12 Urological surgeries,4 Appendicectomy, 3 Cholecystectomy, 4 Hernia surgeries, 3 Hydrocele surgeries,19 Cataract surgeries &,7 other surgeries. Among 200 surgeries, we were found 29 infected cases which showed in table1. We also observed that predisposing factor which were anemia, malignancy, diabetes, chronic illness, immunodeficiency state. We found that 20.6% infected cases with P. aeruginosa followed by E. coli (17.2%), K. pneumonia (10.3%). Bacteroids spp. & Cons 6.8%, S. aureus, Citrobacter & Streptococci which were 3.4%.

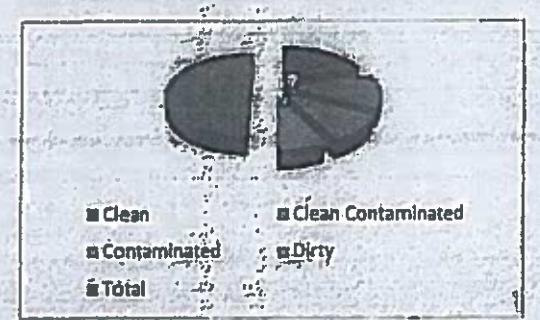

Chart:1 Distribution of cases according to contaminated wound

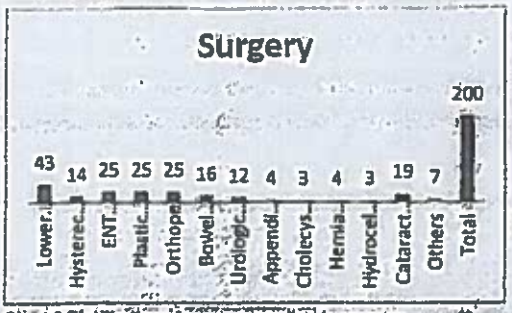

Chart:2 Distribution of cases according to surgery

Table -1 Distribution of cases according to infected cases

Surgery	Frequency	Infected cases
Lower segment caesarean section	43	3
Hysterectomy	14	2
ENT surgeries	25	3
Plastic Surgeries	25	3
Orthopedic surgeries	25	7
Bowel surgeries	16	5
Urological surgeries	12	2
Appendicectomy	4	1
Cholecystectomy	3	1
Hernia surgeries	4	1
Hydrocele surgeries	3	-
Cataract surgeries	19	-
Others	7	1
Total	200	29

Table:-2 Distribution of cases according to predisposing factor

Predisposing factor	Infected cases
Anemia	5
Malignancy	7
Diabetes	4
Chronic illness	3
Immunodeficiency state	1
Other	3
Total	23

DISCUSSION

Out of 200 patients, 29 got infected post operatively. The post-operative infection rate was 14.5% in the present study. Many workers have reported the percentage of post-operative wound infections in range of 10% to 76.9%.[7-11] In this study, the rate of post-operative wound infections could be attributed to the progressive trend towards operating the older patients and performing more complicated procedures on contaminated and dirty surgical

sites. Likewise presence of drain led to development of wound infections with increased frequency. Though drainage provides an outlet for collected serum and blood and prevents haematoma formation, reducing the chances of infection still presence of drain for a longer time may act as a pathway for pathogenic bacteria to enter the wound. Thus, it increases the risk of infection. Similarly, in emergency surgeries, the infection rate was high as compared to the elective ones. Similar observations have been found by other studies also.[12]

Table:-3 Distribution of cases according to isolates

Isolates	No. of organism	Percentage
Staphylococcus aureus	1	3.4
CONS	2	6.8
Pseudomonas aeruginosa	6	20.6
Escherichia coli	5	17.2
Klebsiella pneumonia	3	10.3
Proteus spp.	1	3.4
Citrobacter species	1	3.4
Beta haemolytic Streptococci	1	3.4
Bacteroides species	2	6.8
Total	29	100

Higher infection rates were reported in different kind of surgeries such as bowel surgeries (38.46%), orthopaedic surgeries (29%), urological surgeries (25%), cholecystectomy (21.05%) & appendectomy (18.18%).[13] The reason could be impaired host defenses in these patients and longer hospitalization. In this study, the bacterial isolates obtained indicate a polymicrobial flora. Similar findings were found by other researchers.[14]

Many infections are caused by Gram-negative bacilli. Though, the single most common bacterial isolate was Staphylococcus aureus. The bacterial isolates commonly found were Pseudomonas aeruginosa, E. coli and Klebsiella species, all known to be hospital pathogens. In the present study, isolation of anaerobic bacteria was very uncommon. The antibiotic sensitivity profile of isolates showed that a large number of multidrug resistant strains were common in the hospital environment. Hence, it may be stated that post-operative wound infections occur with more frequency. So, more strict steps are needed to reduce the incidence. Whenever the infection occurs, proper laboratory identification of the pathogen along with its sensitivity profile must be obtained to treat the patient with proper antibiotics. It is also important to watch whether it is causing cross infection or resulting in spread as a hospital infection.[15-17]

It was reported that operative time ≥ 240 minutes was related with increased overall complications.[18] In orthopedic surgeries, post-operatory infections present a significant risk and the use of antibiotics increases the population of pathogens exhibiting resistance against them. Silver nanoparticles seem to be a new therapeutic avenue for their safety. They can be implanted in bone cement for the prevention of infections.[17-19]

It can be concluded that post-operative wound infections are a serious medical problem. It has to be handled properly due to its increased morbidity, mortality and medical care costs. It is recommended that an active surveillance program should be undertaken.

CONCLUSION

Post-operative wound infections are a serious medical problem that has to be tackled due to its increased morbidity, mortality and medical care costs. An active surveillance program is recommended.

A Prospective Study on Use of Teriparatide and Zoledronic Acid in Cases of Osteoporosis

Manish

Assistant Professor, Orthopedics, Ananta Institute of Medical Sciences, Udaipur, Rajasthan

ABSTRACT

Background: Present prospective study is intended to compare role of Teriparatide and Zoledronic acid in osteoporosis as well as in pathological fracture due to osteoporosis so as to help elderly postmenopausal women to combat with osteoporosis & complications arising due to it.
Methods: This study is carried out in the department of orthopedics. Total of 100 women were included at the time of beginning but 20 women were lost in the follow up due to various reasons
Results: 51 patients of group 1 were given Zoledronic acid & 29 patients were given Teriparatide. Patients were evaluated up to 12 months at regular intervals. Serial DEXA scans were done, assessment & comparison were done accordingly.
Conclusions: Treatment of osteoporosis is multimodal with no definitive single molecule available. This study compared Zoledronic acid & Teriparatide. Although T-score has nearly the same value, but our study resulted in increased BMD score & fewer side effects by the use of Teriparatide, so it is concluded that patient with very low BMD requires treatment with Teriparatide.

INTRODUCTION

Osteoporosis is a disease characterized by microarchitectural deterioration of bone leading to increase bone fragility and a subsequent increase in fracture risk. Osteoporosis is operationally defined by WHO as a bone mineral density 2.5 standard deviation or below the young adult mean (T-score <2.5).

BMD increases from birth with nearly 90% of bone mass acquired by age of 20. Peak bone mass is achieved by age of 30, thereafter it begins to decrease slowly.

Osteoporosis is due to many modifiable (drugs & lifestyle) & non modifiable (age related, post-menopausal) factors. Generally, patients with osteoporosis are asymptomatic unless any complication occurs like predominant fracture. Patient present with back pain & increase thoracic kyphosis, she or someone in the family may have noticed that her height has diminished. X-ray of the spine may show wedging or compression of one or more vertebral bodies and often the lateral view also shows the calcification of the aorta.

This is the typical picture, but sometimes the first clinical event is a low energy fracture of the distal radius, the hip or the ankle. Women who have had one low energy fracture have twice the normal risk of developing another.

Osteoporosis is currently being treated by different pharmacological groups available like Bisphosphonate, Teriparatide, Calcitonin, Denusumab etc.

The main focus in this study is to compare the role of Zoledronic acid (bisphosphonate) Vs Teriparatide (recombinant PTH) in osteoporosis as well as in pathological fractures due to osteoporosis.

How to cite this article: Manish. A Prospective Study on Use of Teriparatide and Zoledronic Acid in Cases of Osteoporosis. Int Arch BioMed Clin Res. 2017;3(1):101-104.

Source of Support: Nil, Conflict of Interest: None

DEXA may show significantly reduced bone density in the vertebral bodies or femoral neck. It is highly accurate method that has become the standard for measurement of bone density. It measures usually lumbar spine & hip but in post-menopausal women most sensitive is spine.

Aims & Objectives –

Prime aim of this study is to compare the role of Zoledronic acid & Teriparatide for treatment of osteoporosis & pathological fractures due to osteoporosis for-

1- Long term results after 12 months.
2- Recovery of function after 6 months.
3- Evaluation of BMD.
4- Symptomatic & Functional outcome.

METHODS

This is a prospective study which includes patients of post-menopausal female treated in the Department of Orthopedics.

A total of 100 patients were included in our study group out of which 15 patients did not turn for follow up & 5 patients expired. So, 80 patients were included in our study. 51 patients were given Zoledronic acid & 29 were given Teriparatide.

All the cases which fulfilled our inclusion were included in the study which were randomly categorized in 2 category;

1- Those who were managed by Zoledronic acid (in a dose of 5 mg IV infusion at each sitting over a period of 15 minutes, two such doses at 6 months interval).
2- Those who were managed by Teriparatide (in a dose of 20 micrograms /day by subcutaneous injection for 12 months). The patients with BMD -4 were treated by Teriparatide.

The evaluation of role of both drugs was done by evaluating clinical profile & bone mineral density at different interval of 6 & 12 months.

Inclusion Criteria-

Postmenopausal women between 45 to 85 years of age with-

1 T-score of -2.5 or less at lumbar spine Or
2 T-score of-2.0 or less at femoral neck, total hip or lumbar spine with at least one documented osteoporotic vertebral fracture or a previously documented history of an osteoporotic clinical non vertebral fracture due to trivial trauma.

Exclusion Criteria-

1- Any prior use of strontium
2- Any past or active renal disease
3- Prior treatment with any IV or oral Bisphosphonates longer than 3 months consecutively. If bisphosphonates exposure is less than oe equal to 3 months, a washout period of 1 year to randomization is required.
4- Non osteoporotic forms of metabolic bone disease such as not limited to Paget's disease of bone, osteomalacia, osteogenesis imperfect or multiple myeloma.
5- Less than 3 evaluable lumbar vertebrae (L1 to L4) for DEXA measurement.
6- Treatment with osteoporotic therapies such as Raloxifene, calcitonin or hormone replacement therapy (HRT) within 3 months of randomization.
7- Allergy or previous exposure to Teriparatide.

At the time of admission or beginning of treatment detailed history taken on following points-

-Age, Menopausal status, Drug history, Treatment taken before reporting to hospital, Associated injuries, Any hereditary disease.

-General & systemic examination.

-Local Examination – that includes presenting complaints along with spine tenderness, height, weight & BMI.

-Routine blood investigations-that includes hemogram, RBS, serum urea & creatinine, Complete urine examination, S.osteocalcin, S. estradiol, LFT,S. vitamin D 3 level, S.PTH, S. calcium & Alk. Phosphatase, chest xray, ECG all leads.

-Radiological Examination- Xray (DL spine AP & lateral view, Pelvis-both hip).

BMD (Dexa scan).

If required than CT scan, MRI, Bone biopsy, USG.

Several noninvasive techniques are available for estimating skeletal mass or density, these includes dual energy Xray absorptiometry (DXA), single energy Xray absorptiometry (SXA), quantitative CT & ultrasound. DXA is highly accurate xray technique that has become standard for measuring bone density. Although it can be used for measurement in any skeletal site, clinical determination usually are made of the lumbar spine & hip. In our study DXA is the investigation of choice.

T-Score

T-score the no. of standard deviation above or below the mean for the healthy 30 yrs old of same sex and ethnicity as the patient.

T-score -1 or higher; Normal BMD.

T-score -1 to -2.5; osteopenia

T-score -2.52 or lower; osteoporosis.

All patients were given 1000 mg calcium daily and 800 IU vitamin D daily. All patients were given adequate diet of protein & patient with low BMI given extra dose of protein & encouraged foe weight bearing exercise.

Evaluation of outcome-

The patients were followed up for period of 12 months.

Improvement in clinical profile and BMD at initiation of therapy & each follow up was recorded in a proper case sheet, however the patients were advised to report immediately to the hospital in case they experience any adverse effects of both drugs.

RESULTS

The present study was conducted in the department of orthopaedics, Pacific medical college and hospital Udaipur Rajasthan from Dec 2017 to June 2019 in a consecutive series of patients who presented in the outpatient department with age of 45 to 85 years with osteoporosis who fulfilled inclusion criteria of the study.

This is a prospective cohort study and patients were randomly allocated into two treatment group (group 1 patients were managed by Zoledronic acid and group patients were managed by Teriparatide) according to the order one by one.

A total of 100 patients were included in the study out of which 15 patients did not turned for follow up for 6 months and 5 patients expired. So, 80 patients were included in the study group out of which 51 patients was given Zoledronic acid and 29 patients was given Teriparatide.

Table 1: Age distribution in Zoledronic acid group

AGE GROUP(in years)	No. of patients	Percentage
45-55	12	23.52%
55-65	17	33.33%
65-75	12	23.52%
75-85	10	19.60%
TOTAL	51	100

Table 2: Age distribution in Teriparatide group

AGE GROUP (in years)	No. of patients	Percentage
45 - 55	6	20.68%
55 -65	13	44.82%
65 -75	7	24.13%
75 -85	3	10.34%
TOTAL	29	100%

Table 3: Clinical profile

Variable	Zoledronic acid (no. of patients)	Teriparatide (no. of patients)
Decrease in bone pain	32	25
Increase physical activity	29	25

Table 4: Decreased risk of pathological fractures

Variable	Zoledronic Acid (n=14)		Teriparatide (n=10)	
Decreased risk of refracture (pathological fracture)	Vertebral	Non-Vertebral	Vertebral	Non-Vertebral
	5	2	6	2

Table 5: Side effects

Side effect	No. of cases(zoledronic acid)	No of cases(teriparatide)
No	29	24
Fever	8	1
Nausea	2	-
Malaise	2	-
Flu like symptoms including arthralgia	10	1
Skin side effects	-	2
Mild dizziness and leg cramps	-	1

Table 6: Mean bone mineral density in form of T – score at each follow up

Time interval	Zoledronic acid(no. of patients)		Teriparatide(no. of patients)	
0 (initial)	-	2.77	-	2.74
6 months	-	2.67	-	2.59
12 months	-	2.64	-	2.53

Table 7: Mean and standard deviation of T score

T-score	0 MONTH		6 months		12 months	
	Zoledronic acid	Teriparatide	Zoledronic acid	Teriparatide	Zoledronic acid	Teriparatide
Mean	-2.77	-2.67	-2.67	-2.59	-2.64	-2.53
SD	0.189	0.324	0.185	0.294	0.186	0.256
n	51	29	51	29	51	29

Table 8: Average increase in BMD

Time interval	Zoledronic acid group	Teriparatide group
6 months	3.61%	5.47%
12 months	4. 69%	7.58%

Bone mineral density:

Before treatment – Zoledronic acid – 2.77 and Teriparatide – 2.74

Mean T- score in both groups was near same value

At 6 months - Zoledronic acid – 2.67 and Teriparatide – 2.59

At 6 months p value >0.05. so, no significant difference in increase in mean T- score in Teriparatide group than Zoledronic acid.

At 12 months - Zoledronic acid – 2.64 and Teriparatide – 2.53

At 12 months p value <0.05 so significant difference in increase in mean T- score in Teriparatide group than Zoledronic acid.

Average percentage increase in BMD from initial to final in Teriparatide – 7.58%

And the statistical significance at initial p =0.65, at 6 months p = 0.14 and at 12 months p = 0.01, value are p< 0.005

Overall after complication of study p <0.01 which is <0.05 means significant increase in BMD in Teriparatide group.

DISCUSSION

Various studies have been conducted to evaluate the best treatment of osteoporosis however, no single treatment has been proven to be superior over other treatment.

In this study only postmenopausal women in the age group of 45-89 year included. Mean age of Zoledronic acid group is 62.3 year & in Teriparatide group it is 62.7 year with a mean age of 62.5 year. In Meenal Jain et al[1] mean age for Zoledronic acid group is 60.4 year & for Teriparatide group is 60.69 year.

In Cosman et al[2,3] study –mean age was 65.9 years.

In our study we have included postmenopausal women only which is consistent with previous studies too.

In this study bone pain decreased in 62.7% & 86.2 % in Zoledronic acid & Teriparatide group respectively.

In Zoledronic acid group 49% cases demonstrated increase in physical activity while in Teriparatide group had 86.2 % women increase in physical activity.

In our study, Zoledronic acid group had 62.5% decreased risk of vertebral fracture & 33.3 % decrease risk in non-vertebral fracture. In Teriparatide group this reduction in risk was 85.7% & 66.65 % respectively.

Black DM et al[4] –once yearly Zoledronic acid for treatment of post-menopausal osteoporosis reduces the risk of vertebral fractures by 77% & non vertebral fractures by 25 %.

Robert M Neer et al[5] effect of PTH on fracture & BMD- in post-menopausal female shows vertebral fracture reduction risk 90% & non vertebral fracture risk reduction 53 %.

Teriparatide group had fewer adverse effects as compared to Zoledronic acid group which mainly consist of fever, nausea, leg cramps, dizziness, flu like symptoms.

Cosman et al[2] – Rate of adverse effect within the first 3 days after infusion of Zoledronic acid is 58.45% and 27% with Teriparatide whereas those after 3 days were comparable across both groups.

In our study improvement in mean T-score was quite superior in Teriparatide group as compared to Zoledronic acid at the end of 12 months.

Average increase in BMD from initiation to cessation of treatment are 4.69 % and 7.58 % in Zoledronic acid & Teriparatide group respectively.

Meenal Jain et al[1]- percentage change in BMD Zoledronic acid was 4 to 6 % and it was 8 to 10 % in Teriparatide group.

CONCLUSION

The result of this study shows that average increase in BMD was significantly greater in Teriparatide group (7.5%) than Zoledronic acid (4.1%).

The slightly higher values in clinical profile improvement were observed in group treated by Teriparatide as compare to Zoledronic acid.

Risk of refracture reduction is greater in Teriparatide group than Zoledronic acid. Some adverse effects were observed after infusion of Zoledronic acid, they used to appear usually within 48 hours that mainly includes fever, malaise, arthralgia, restlessness, headache but none of the case showed any change in liver or renal functions.

The patients with hypercalcemia, hyperparathyroidism, multiple myeloma, Paget's disease & bone malignancies were not given Teriparatide as it is against the pharmaco-physiological action of Teriparatide.

This study concludes that both Zoledronic acid & Teriparatide are good options for treatment of postmenopausal osteoporosis with supplementation therapy of vitamin-D & calcium.

It is concluded that the patients with very low BMD profile require treatment with Teriparatide as they do not respond very well to Zoledronic acid.

Evaluation of functional outcome of cemented bipolar hemiarthroplasty for treatment of osteoporotic proximal femoral fractures in elderly people

Shivanand C Mayi, Sachin Shah, Sadashiv R Jidgekar and Arunkumar Kulkarni

Abstract
Background: In India the estimated geriatric population is going to rise from 8% of total population in 2010 to 19% by 2050. Incidence of osteoporosis and associated fractures will rise in coming years with increasing elderly population. Management of fracture neck of femur and unstable intertrochanteric fractures in osteoporotic bone is challenging in elderly as they are more prone for fracture associated complications like pressure sore, deep vein thrombosis and pneumonia.
Aim: The purpose of this study is to evaluate the role of cemented bipolar hemiarthroplasty in management of osteoporotic proximal femoral fractures in elderly people.
Patients and Methods: In this prospective study twenty patients with osteoporosis having proximal femoral fractures (fracture neck of femur/unstable intertrochanteric fracture) were treated by cemented bipolar hemiarthroplasty. Patients were followed up at 3 weeks, 3, 6, and 12 months to evaluate the function outcome. Mean age of the patients in this study was 73.84 years.
Results: Average duration follow up in this study was 14.63 month. Mean Harris Hip Score in the post-operative period was 42.73 ± 8.78 which improved to 81.57 ± 9.11 at 6 months. Average post-operative mobilization duration was 3.84 day and average hospital stay was 11.31 day. At 1 year follow up 85% patients had excellent to fair outcome and 10% had poor outcome.
Conclusion: Treatment of osteoporotic proximal femoral fractures with cemented bipolar hemiarthroplasty gives better functional outcome.

Keywords: Proximal femoral fractures, elderly, osteoporosis, cemented bipolar hemiarthroplasty

1. Introduction

Elder age group is more prone for the fragility fractures of proximal femur mainly fracture of neck of the femur and unstable intertrochanteric fractures. According to United Nation, people more than 60 years of age are considered as elderly people [1]. Elderly people may have fragility fractures after minor trauma. Fracture caused by sideway fall from standing height are defined as fragility fractures [2]. These fractures have a slow initial velocity on the greater trochanter and mainly include trochanteric hip and fractures of femoral neck [3]. Osteoporosis plays a major role among many risk factors which cause fracture of the bone in this age group. Both male and female sexes are prone for osteoporosis in elderly age group but in comparison with females, males develops osteoporosis later in life and osteoporosis-related fractures risk is less [4].

Fractures of proximal femur in elderly patients are associated with impaired mobility, morbidity, mortality and bad effect on the daily living of the patient because of loss of independence [5]. Osteoporosis in these patients with fracture neck of femur or unstable intertrochanteric fractures makes internal fixation difficult with poor out come due to implant and bone related complications such as head perforations, plate pullout, plate breakage, avascular necrosis of femoral head and non-union of femoral neck fracture [6, 7].

Displaced femoral neck fractures in elderly patients give better hip function and lesser reoperation rate if treated with cemented hip arthroplasty in comparison with internal fixation [8, 10]. Bipolar hemiarthroplasty has advantage of reduction of acetabular wear due to dual-bearing system [11].

Cemented bipolar arthroplasty is treatment of choice in freely mobile elderly patients with an intertrochanteric femoral fracture [12].

Most common treatment for displaced femoral neck fractures in elderly is hemiarthroplasty [13] which gives better functional outcome [14]. The aim of this study is to analyze the functional outcome of the proximal femoral fractures in elderly patients with osteoporosis which were treated by cemented bipolar hemiarthroplasty.

2. Materials and Methods

This prospective study was conducted at the Department of Orthopaedics, KBN Teaching and General Hospital attached to KBN Institute of Medical Sciences in Kalaburagi after getting clearance from ethical committee. Between October 2013 and June 2015, 20 elderly patients admitted with either unstable intertrochanteric fracture or fracture neck of the femur with associated osteoporosis were selected for this study. Inclusion criteria were elderly patient (>60 years) with walking ability, unilateral fracture neck of femur / unstable intertrochanteric fracture and Singh's Index < 3 on X-ray of both hips. Poly trauma patients, old contralateral hip fracture, osteoarthritis of hip involved, history of mental illness, pathological fracture and fractures older than 48 hours at admission were not included in the study.

All the 20 patients were admitted to casualty ward and immobilization of the fracture was done by skin traction. X-Ray of the pelvis with both hips and lateral view of the affected hip was taken. Classification of the fracture and assessment of severity of osteoporosis by Singh's index was done. Complete blood investigations were done to know the general health status of the patient. Treatment was started for osteoporosis and other associated medical problems.

Patients were posted for surgery within 48 hours of admission after optimization and pre anesthetic checkup. All the operations were performed by experienced orthopaedic surgeon under spinal anesthesia. Posterior approach was used with the patient in lateral decubitus position. Diameter of extracted femoral head was measured and appropriate size bipolar prosthesis was fixed after reaming the femoral canal with 2nd generation cementing technique (Figure 1). Lesser and greater trochanter fragments in unstable intertrochanteric fractures were reduced to main fragment with SS wire, after which the bipolar prosthesis was fixed with second generation cementing technique (Figure 2). Care was taken to restore the neck length, femoral head offset and anteversion to get a stable hip joint after reduction. Soft tissue repair was done after confirming the stability of the joint and wound closed in layers over suction drain.

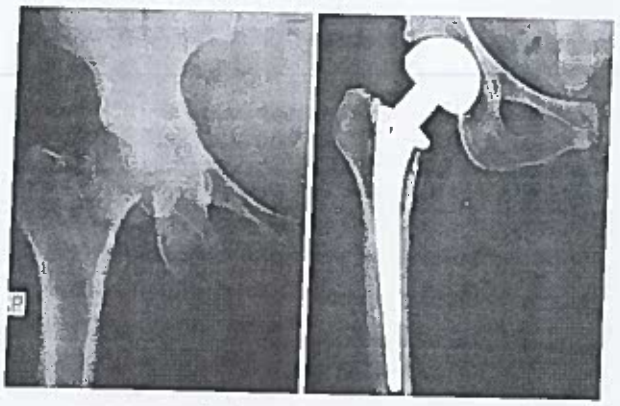

Fig 1: Implant fixation in fracture neck of the femur

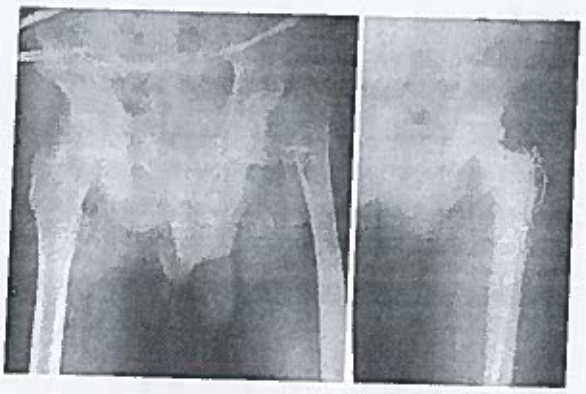

Fig 2: Reduction of trochanteric fragments with SS wire in unstable intertrochanteric fracture.

Post-operative intravenous antibiotics were given for 5 days. Patients were encouraged weight bearing from 2nd post-operative day after drain removal. Sutures were removed on 12th post-op day. Patients were advised to use some type of walking aid (cane/frame) up to 3 months or till they are comfortable to walk without support to avoid falling again. They were also advised to avoid squatting in future. After discharge patients were followed up at 3 weeks, at 3 months, at 6 months and at 12 months for functional evaluation of operated hip joint. Functional evaluation was done by Harris Hip Score and X-ray of the hip joint was taken to note the implant position.

Statistical analysis of the data was done and reported as mean, percentage and standard deviation.

3. Results

20 elderly patients were enrolled in this study having osteoporosis and unilateral proximal femoral fracture (unstable intertrochanteric fracture/ fracture neck of the femur). Average duration of follow up in this study was 14.63 month (12-22 months). One patient expired 1 month after surgery because of other medical condition and was not included in the final assessment. Average age of the study population was 73.84 year (63-96 years). 14 patients were walking without any support before the injury and five with the support of single cane. 18 patients had history of a simple fall at home or while walking on ground and one patient had RTA. Ten patients had fracture neck of femur and 9 had unstable trochanteric fracture. Other patient data is as depicted in table 1.

Table 1: Patient Data

Patients	Numbers/Mean
Total patients	19
Mean Age of patients	73.84 ± 8.75 year
Male : Female	6:13
Hip joint operated	
Right side	9
Left side	10

*Orthopedic Trauma Association *Ischemic Heart Disease

Average post-operative mobilization duration was 3.84 day (3-7 days) and average hospital stay was 11.31 day (7-21 days). Mean Harris Hip Score (HHS) in the post-operative period was 42.73 ± 8.78, which improved to 63.84 ± 8.37 at 3 weeks. There was gradual improvement in HHS at 3months, 6 months and up to 1 year after surgery (Table 2). The functional outcome is given in table 3.

Table 2: Mean Harris Hip Score during follow-up

Follow up at	Mean Harris Hip Score
Post-operative period	42.73 ± 8.78
3 weeks	63.84 ± 8.37
3 months	74.10 ± 7.78
6 months	81.57 ± 9.11

Table 3: Functional outcome at 1 year

Harris Hip Score Grading	Number of patients	Percent	Cumulative Percent
Excellent (90-100)	01	5	5
Good (80-89)	15	75	80
Fair (70-79)	01	5	85
Poor (< 70)	02	10	95
Not evaluated (Death)	01	5	100
Total	20	100	

Two patients in the study developed Grade-1 pressure sore which healed with local care and ambulation of the patient. One patient had deep vein thrombosis (DVT) which resolved with low molecular weight heparin therapy for 2 weeks. Two patients had urinary tract infection which responded to antibiotic therapy.

4. Discussion

Since, the elderly population in India is expected to rise from 8% of total population in 2010 to 19% by 2050 [15] an increase in cases of osteoporotic proximal femoral fractures is expected in coming days. Proximal femoral fracture in elderly people with osteoporosis is a big challenge for treating orthopedic surgeon in view of intra & post-operative complications along with functional outcome. Review of the literature shows different opinions about the management of osteoporotic proximal femoral fractures in elderly patients. Early prosthetic replacement decreases morbidity and mortality in geriatric age group with fracture neck of femur, and primary hemiarthroplasty is the recommended treatment option for elderly patients with poor bone stock having unstable intertrochanteric fractures [16]. In our study we have included proximal femoral fractures (fracture neck of femur/unstable intertrochanteric fracture) in elderly patient who are having osteoporotic bone and were managed by cemented bipolar hemiarthroplasty.

A study on unstable osteoporotic intertrochanteric fractures in elderly found that 91% patients had excellent to fair functional results [6]. In our study 85% of patients had excellent to fair functional outcome with HHS which is comparable to above study. Another similar study on proximal femoral fractures in elderly with severe osteoporosis reported excellent to fair results in 92% of study population [17].

Mean HHS after hemiarthroplasty for displaced femoral neck fractures in elderly was 79.3 at 12 months follow-up [11]. Our study result is comparable to above mentioned study with HHS of 84.26 at 12 months follow-up. Another study on cemented bipolar hemiarthroplasty for fracture of femoral neck reported excellent to fair results in 86% of patients [7] with their grading system of patients ambulatory status which is comparable our study results. Different studies have mentioned about the complications associated with hemiarthroplasty in eldery like, wound infection, DVT, pressure sores, joint dislocation, implant loosening and acetabular erosion. Grade-1 pressure sores were reported in 4 patients [18] (n-25) and we had 2 patients (n-19) with grade-1 pressure sores which is less compared to above study because of early mobilization of patients on 3rd post-operative day. In the post-operative period DVT was reported in 9.6% study population [7] compared to our study where 1 patient (5.26%) developed DVT. Mortality rate reported in a study was 5.4% within 6 months of surgery [6] which is comparable with our study result of 5.

The limitation of this study is the short duration of follow up. Further studies are required on management of these fractures with large sample size and long duration of follow up to know the long term outcome of this treatment option.

5. Conclusion

The authors believe that cemented bipolar hemi arthroplasty is a better treatment option for the fractures of proximal femur in elderly people with osteoporotic bones as it helps in early mobilization thus, preventing complications associated with fractures around hip in this age group. Elderly patients treated with cemented bipolar hemiarthroplasty have better functional outcome in osteoporotic proximal femoral fractures.

the JESS frame after callus becomes visible on radiograph and as pain allows. It is a cost effective treatment option in these patients where non operative treatment or internal fixation becomes difficult. As follow up period in our study is of short duration we could not comment on the limb length discrepancy in our patients. Further studies with similar treatment and longer duration of follow up are required to assess the long term outcome of JESS in these fractures.

CONCLUSION

Our study results shows fractures of the distal third tibial shaft and distal tibial physis with associated soft tissue injury can be well managed by JESS. In these patients who cannot be managed by cast application, JESS helps in the wound care and fracture stabilization without affecting the fracture healing process.

ABSTRACT

Background: Injuries around ankle and distal third of tibial shaft are among common paediatric bone trauma. Some of these cases are associated with soft tissue injury over the lower third of leg or around the ankle joint as tibia is subcutaneous on the anteromedial aspect. This study was conducted to know the outcome of these injuries with minimal invasive external fixation.
Methods: Eleven patients in the age group of 4-14 years were included in this study. All patients had closed fracture of distal third tibial shaft or injury of distal tibial physis with associated soft tissue injury. Joshi's external stabilization system was used to retain the reduction of fracture and appropriate wound care was taken. JESS was removed after radiological signs of fracture union.
Results: Patients were followed up for mean period of 8.9 month. After JESS fixation healing of wound occurred at an average of 12.45 day and external fixator was removed at 6-8 weeks period. Three patients had grade 1 pin tract infection which was controlled by local dressing. No patient had stiffness of ankle at the time of JESS removal. No limb length discrepancy was seen in any of the patients in this study at their final follow up.
Conclusions: JESS gives good results in fractures of distal tibial with associated soft tissue injury. It helps in better management of wound and fracture stabilization.

Keywords: Distal tibial fracture, Epiphysis, Soft tissue injury, External stabilization

INTRODUCTION

Tibial and fibular shaft fractures are the third most common among long bones in children contributing up to 15% after radial/ulnar and femoral fractures.[1] Fifty to 70% of these fractures occur in distal third of tibia.[2] In children from 1 to 4 years of age group bicycle spoke injuries to tibia are common, whereas 4 to 14 years of age are due to sports and road traffic accidents.[2] Nine percent of fractures of tibia in children are open.[2]

These fractures are most commonly associated with concomitant fractures of the ankle. Fractures of the tibia constitutes up to 10-15% of all fractures in children and are also most common lower limb fractures in paediatric age group.[3]

Distal tibial and fibular physeal injuries account for 25% to 38% of all physeal fractures and are second most common to get injured among growth plate injuries.[4,5] Poland in his monograph (1898) pointed out that forces which result in ligament injury in adults causes fractures of the physis in children as ligaments are stronger than the physeal cartilage.[2] Distal tibial physeal fractures are classified according to Salter-Harris anatomical classification.

Closed fractures of tibial shaft in children are usually treated by non-operative methods. Open fractures and fractures with associated soft tissue injury requires operative fixation of fracture for proper wound care.[2] Distal tibial and fibular physeal fractures require accurate reduction and fixation to avoid future growth disturbance.

The aim of this study is to assess the role of Joshi's external stabilization system (JESS) in the management of these fractures associated with soft tissue injury

METHODS

From December 2013 to January 2016, 11 children with injury to the distal tibia and fibula with associated soft tissue injury were surgically managed by JESS. Institutional ethical committee clearance was taken for this study. All patients presented to emergency department with history of trauma to leg and associated wound over the ankle region. Patients were initially stabilized in the casualty department and radiograph of the involved leg was ordered after cleaning and dressing of the wound.

Patients below the age of 18 years with fractures of the distal third tibia and fibular shaft or distal tibial and fibular physeal injury with associated soft tissue injury over the fracture site were included in this study. Closed fractures of shaft of both bones of leg and closed undisplaced fractures of distal tibial and fibular physis without soft tissue injury and patients above 18 years of age were not included in the study.

Relevant patient data was collected after taking informed consent to participate in the study from the parent/guardian of the child. Surgical procedure and wound care process was explained to the attendant of the patient. Radiographs of all the patients were assessed for the fracture site, amount of displacement and type of growth plate injury in ankle fractures. Ankle fractures were classified according to Salter-Harris anatomic classification of physeal fractures.[6]

Patients were taken for surgery within 24 hours of injury after getting clearance from the paediatrician and anaesthetist. Under spinal anaesthesia thorough debridement and irrigation of the wound was performed. Fractures of the distal tibial metaphysis were reduced under image intensifier guidance and stabilized with two kirschner wires (K-wire) of 1.5 mm to 3 mm size both in the proximal and distal fragments as shown in Figure 1. During the surgery care was taken to avoid the wires passing through the injured soft tissue or wound. These wires were interconnected with JESS connecting rods on either side using JESS clamps. Patients with distal tibial physeal injury were also fixed with smooth pins or K-wires after accurate reduction of the fracture fragments under image intensifier. One or two K-wires were passed through the distal tibial epiphysis and physis up to the opposite cortex of metaphysis depending on the fracture pattern as given in Figure 2. Unstable fractures of the fibula after fixation of the tibia were fixed with an intramedullary K- wire. No fixation was done for stable fibular fractures.

In the postoperative period ankle movements were encouraged from day one. Appropriate antibiotics were given by intravenous route. Proper care of the wound and pin tracts were done to avoid infection. Radiographs were taken at 1 week, 3 weeks, and 6 weeks to see the fracture union and retention of reduction. After healing of the wound patients were encouraged partial weight bearing with JESS at 4 weeks or as the pain allowed. JESS was removed after radiological union of the fracture and care of pin tract wound was taken till they healed. Post JESS removal patients were followed up at 3 months and 6 months.

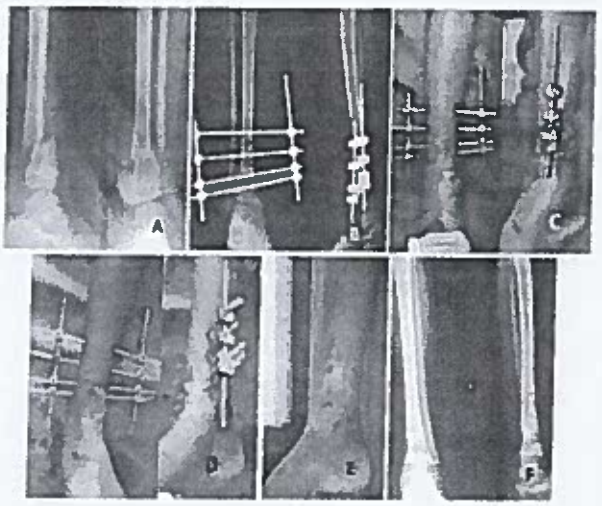

Figure 1: Distal tibial metaphyseal fracture with wound.
A) Pre-op, B) Post-op X-ray (C) Clinical picture of initial wound & (D) Healed wound, (E&F) After JESS removal.

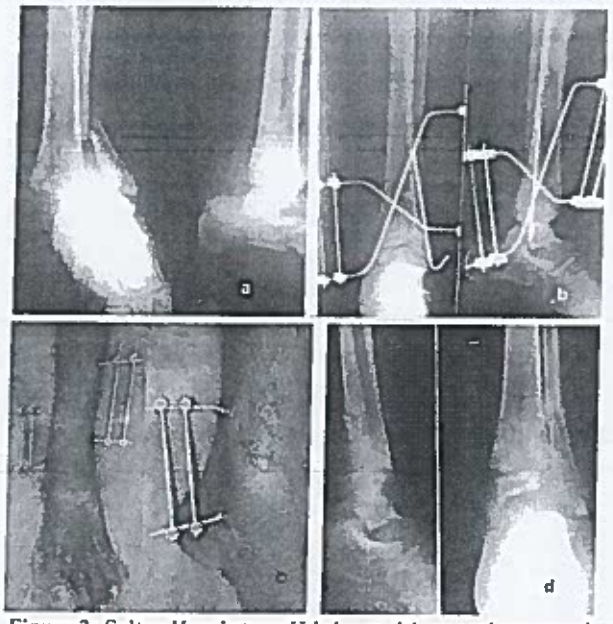

Figure 2: Salter-Harris type II injury with wound managed by JESS.

Data analyzed for type of fracture, wound healing period, duration of fracture union and complications.

RESULTS

This study included 11 patients aged between 5-14 years. All the patients had fractures of distal tibial metaphysis or epiphysis and distal fibula with soft tissue injury over lower part of leg and ankle joint. All the patients were managed by JESS apparatus after closed reduction of fracture with appropriate frames. Average age of the study population was 9.27±3.03 year. Males were predominant in this study with road traffic accident (RTA) being the frequent cause of injury. Four patients had fracture of distal metaphysis of the tibia and other seven had distal tibial physeal injury. No patients had any neurovascular injury. Other demographic data of the patients are as given in Table 1.

Table 1: Demographic data of the patients.

Variables	Number (%) (n=11)
Mean Age ± SD	9.27±3.03 year
Sex of the patients	
Male	8 (72.72%)
Female	3 (27.27%)
Fractures operated	
Right side	6 (54.54%)
Left side	5 (45.45%)
Mode of injury	
Road traffic accident	6 (54.54%)
Fall from height	4 (36.36%)
Fall of weight on leg	1 (9.09%)
Fracture type (distal tibial physis)	
Salter-Harris type 2	6 (54.54%)
Salter-Harris type 3	1 (9.09%)
Distal tibial metaphysis fracture	4 (36.36%)

Table 2: Results of JESS.

Variables	Mean ± SD	Range
Duration of wound healing	12.45 ± 3.88	6-21 Days
Partial weight bearing	5.09 ± 0.7	4-6 Weeks
JESS removal	6.63 ± 0.8	6-8 Weeks
Full weight bearing	7.09 ± 0.94	6-9 Weeks

Patients were followed up for an average of 8.9±2.38 months (6-12 months). Duration of wound healing ranged between 8-21 days in these patients with an average of 12.45 day. Time at which partial weight bearing was started ranged from 4 weeks to 6 weeks. JESS fixation was removed at an average of 6.63 week and full weight bearing was started at an average of 7.09 week as shown in Table 2. All the patients had radiological union at the time of full weight bearing. Three patients had grade-I pin tract infection which healed with local care. No patients in the study had limb length discrepancy at their final follow up which ranged from 6 months to 12 months. All the patients had normal range of ankle movements after removal of the JESS.

DISCUSSION

Fractures around the ankle and distal third tibial shaft are common in pediatric age group. Incidence of distal tibial fibular physeal injuries account for 25-38% of all physeal fractures.[4] Another study reported that ankle fractures in children account for 5% of pediatric fractures and 15% of physeal injuries.[6] Physeal injuries are more common than ligament injuries in pediatric age group as ligaments are stronger than open physis.[6] Almost up to 58% of these distal tibial and fibular physeal injuries occurred during sports activities.[7,8] Incidence of physeal ankle fractures is more in male than in females.[9] Commonest age group for tibial physeal fractures is around 8-15 years.[9] Schurz et al found that an adduction trauma to the ankle being the common cause of injury followed by abduction trauma.[10]

Distal tibial physeal injuries require appropriate treatment otherwise which could lead to deformities and limb length discrepancy. Incidence of growth abnormalities is high in Salter-Harris type III and IV injuries and less in type II fractures.[9] Damage to the proliferative layer of cells in the growth plate may occur due to fracture passing through the physis in type III and IV lesions with high risk of growth disturbences.[11] Distal tibial physeal injuries require an absolute anatomical reduction by closed or open technique to decrease the rate of epiphysiodesis and related problems.[11]

Operative treatment is recommended in unstable fractures of distal tibial metaphysis and physis or when these fractures are associated with soft tissue injury.[2] When these fractures are associated with soft tissue injury over the lower part of leg and ankle, appropriate wound care becomes difficult task with plaster cast. External Fixator serves both the purposes of fracture stabilization and soft tissue healing with minimal added trauma to the initial injury. JESS can be used these children with convenient frames according to the fracture stability and type and stiffness of the JESS can be adjusted depending on the K-wire size used.[13] In elder children the axial stability of the JESS can be increased by using thicker K-wires. In JESS as we are using smooth pins in the bone, these can be passed through the physis and connected to the frame to give stable fixation to fracture.

In literature closed reduction and cast application of closed distal tibial fractures and management of open fractures by internal or external fixation is discussed in detail. Not much of literature available on distal tibial fractures with soft tissue injury. Our study was conducted to see the results of these fractures managed with minimal invasive external fixation with JESS. Wound healing is better with JESS fixation and soft tissue injuries resolve faster in these patients. Stiffness of the nearby joints does not occur as we can mobilize the joints earlier. Partial weight bearing can be started along with

ABSTRACT

Background: Treatment of unstable trochanteric fracture is much more challenging than stable fracture. These fractures require stable fixation to minimize the fracture and implant related complications. Need of this study is to assess the suitable implant for stable fixation of unstable trochanteric fracture with less intra and postoperative complications and good functional outcome.

Methods: In this prospective randomized comparative study, 64 patients were distributed into two groups. Group A consisted of patients treated by proximal femoral nail (PFN) (n=32) and group B treated by dynamic hip screw (DHS) (n=32). All the patients were evaluated preoperatively and surgery was done according to the group they were allotted. Post-operative follow up was done at 6 weeks, 3, 6 and 12 months.

Results: Average age of the patients in this study was 51.26±10.24 year. In this study patients were followed up for an average of 10.87±2.61 month. The duration of surgery was shorter in PFN group. Weight bearing was earlier in PFN group than DHS group. Mean functional ability score was better in PFN group with significant gain in function earlier as compared to DHS group.

Conclusions: PFN is a better implant for internal fixation of unstable trochanteric fractures which allows early mobilization and has got better functional outcome score in early postoperative period than DHS.

Keywords: Unstable trochanteric fracture, Proximal femoral nail, Dynamic hip screw

INTRODUCTION

The stability of the trochanteric fracture depends on the amount of contact between the proximal and distal main fragments. Trochanteric fractures with comminution of posteromedial buttress exceeding simple lesser trochanteric fragment or with subtrochanteric extension are termed as unstable. In 3-part fractures stability is inversely proportional to the size of the lesser trochanteric fragment. Instability occurs when more than 50% of the calcar is affected allowing the proximal fragment to collapse into varus with shortening. Reverse obliquity fracture is unstable fracture in which major fracture line extends outward and downward from the lesser trochanter.

Unstable trochanteric fractures are technically much more challenging than stable fractures. Stable reduction of an intertrochanteric fracture requires providing medial and posterior cortical contact between the major proximal and distal fragment to resist varus and posterior displacing forces. For unstable fractures intramedullary implants are (biomechanically) superior.[1] Lag screw cut-out failure following fixation of unstable intertrochanteric fractures in osteoporotic bone remains an unsolved challenge.[2]

The double screw construct provides significantly greater resistance against varus collapse and neck rotation in comparison to a standard DHS lag screw implant.[3] Less sliding of the femoral neck screws was noted with two-femoral neck screw configuration.[2] This study was conducted to assess the suitable implant for stable fixation of unstable trochanteric fracture with less intra and postoperative complications and good functional outcome which should be the goal of every orthopaedic surgeon treating these fractures.

METHODS

Between October 2013 to July 2015, 64 patients with unstable trochanteric fracture were randomised into two groups to be treated with PFN or DHS. Institutional ethical committee was informed and clearance was taken for the study. All the patients admitted to our hospital in the age group of 20-60 years with fresh unstable trochanteric fracture willing to participate in the study were allotted to PFN or DHS group. Random allocation of the treatment modality was done after taking informed consent from the patients. Polytrauma patients, pathological fracture, patients who were not able to walk independently before the injury and patients who refused to give consent were excluded from the study.

After admission relevant blood investigations and plain radiographs of the both hips AP view and involved hip lateral view were taken. Fracture classification was done according to Arbeitsgemeinschaft für Osteosynthesefragen (AO) / Orthopaedic Trauma Association (OTA) classification. The type of treatment was according to randomized table in Microsoft Excel. Pre-operative data about the mode of injury and pre injury ambulatory status of the patient was collected. Patients were taken for surgery within 48 hours of admission after clearance from the anesthetist. All the patients were operated by same surgical team.

All the patients received preoperative antibiotics. Operation was done by standard approach using DHS and PFN. All surgeries were done under the guidance of image intensifier. Lateral approach was used for DHS (Figure 1). PFN was done by standard cephalomedullary approach through the modified medial trochanteric portal (Figure 2).[4] Physiotherapy was started on first postoperative day. Partial weight bearing was started as and when patient is comfortable with walker support. Full weight bearing was allowed after radiological union of fracture and patient was free of pain. Follow up study included clinical examination with functional assessment according to Larson's hip evaluation chart 2 (higher the score better the functional outcome). 1st evaluation was carried out at 6 weeks postoperatively. Subsequent follow up evaluation was carried out at 3 months, 6 months and one year.

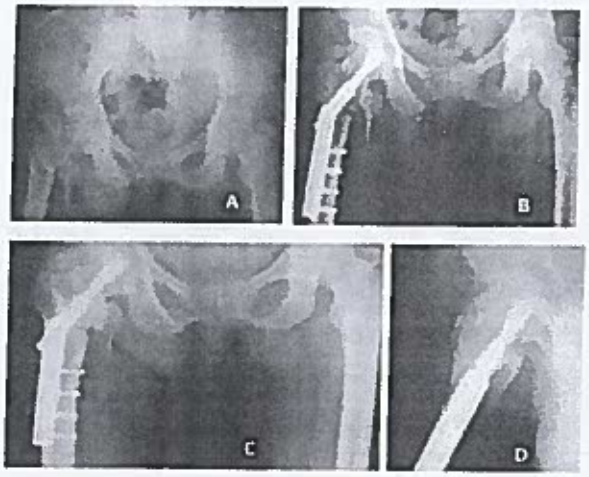

Figure 1: Patient treated by DHS. A) preoperative; B) postoperative; C) X-ray; D) follow up X-ray at 6 months.

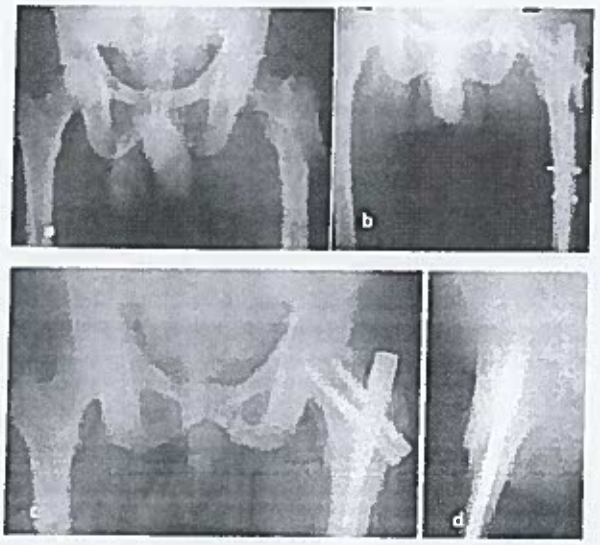

Figure 2: Patient treated by PFN. A) preoperative; B) postoperative; C) X-ray; D) follow up X-ray at 6 months.

RESULTS

In this randomized comparative study consisting 64 patients, DHS was used in 32 and PFN in other 32 patients. The average age of patients in this study was 51.26 ± 10.24 year (22-60 years). Other demographic data of the study individuals and fracture pattern are as given in Table 1. Follow up period ranged from 6 months to 18 months with an average of 10.87±2.61 week. Patients in the age range from 20 years to 50 years had history of high velocity injury (RTA or fall from height) and most of the patients from 51 to 60 years age had history of low velocity injury (simple fall while walking) in this study. Predominant fracture type in this study was 32A2.3 (53.12%) according to AO/OTA classification.

significant

Mean duration of surgery in PFN group was 60.25±10.24 minute and 90.78±8.04 minute in DHS group. Mean duration after which patient started weight bearing was 4.96±1.63 week in PFN group and 8.03±2.26 week in DHS group (Table 2). One patient with DHS died 2 months after surgery because of cardiovascular problem and was not included in the final assessment of the functional outcome. One patient in DHS group had superficial wound infection which healed with regular dressing and antibiotic therapy. One patient developed palsy of common peronial nerve after operating with DHS for which foot drop splint was given at the time of mobilisation. Mean shortening of the affected limb in DHS group was 1.55±0.49 cm as compared with 1.21±0.74 cm in PFN group (Table 2).

Three patients in the PFN group and six patients in the DHS group complained of pain in the operated hip region up to 6 months post operatively. Difference in functional outcome between the groups was seen in post-operative pain and gait components of the Larson's chart 2 score. Values in functional ability and anatomic assessment were not significant. Within the groups all the components of Larson's hip evaluation chart 2 were significant when compared at 6 weeks and 3 months. Total score of all four components of scoring system were significant between the two groups at 6 weeks, 3 months and 6 months (Table 3).

DISCUSSION

These days surgical fixation is the preferred mode of treatment option for unstable trochanteric fracture as it decreases the complications and morbidity associated with these fractures. DHS being the implant of choice in the surgical management of trochanteric fractures has given good results in stable fractures as compared to unstable trochanteric fractures.[5] PFN being an intramedullary device gives better fixation of the trochanteric fracture by restoring the anatomy of the hip.[6] PFN gives biomechanically stable construct allowing early weight bearing in unstable trochanteric fractures.[7,8]

Many studies recommended PFN for the surgical treatment of unstable trochanteric fractures as controlled compression of fracture occurs without rotational malalignment of the fracture fragments.[9-11] The patients treated with PFN were able to walk earlier than those treated by DHS as reported by many studies.[6,8,12] This finding was also seen in our study.

Unstable trochanteric fractures treated with DHS were associated with higher incidence of complications.[9] Fractures treated with DHS results in greater impaction of the fracture with shortening of the femoral neck.[6] Many studies reported longer duration of surgery and greater blood loss in DHS group.[6,13,14] In our study shortening was more and weight bearing was started late in patients treated with DHS as compared to patients treated with PFN. DHS is associated with a higher incidence of complications when used in unstable trochanteric fractures.[9]

Functional score in patients treated with PFN was better than DHS in the first 3 months.[15] Patients who were treated by PFN restored walking ability earlier as compared to those treated by DHS.[6] Our study results were similar to above study findings. Restoration of function is better with PFN when compared with DHS. In our study Functional outcome was better in patients treated with PFN compared to the patients treated with DHS in the initial 6 months of postoperative period. The follow up period in this study ranged from 6 months to 18 months because of the non-compliance from the patient side for subsequent follow up. Patients were reluctant to come for follow up once they did not experience pain in the operated hip and have started walking independently.

CONCLUSION

Our study results suggest PFN as better implant for the treatment of unstable trochanteric fractures when compared to DHS. PFN being an intramedullary implant gives stable fixation to these types of fractures and helps in earlier mobilisation of patients thus, minimizing the complications associated with unstable trochanteric fractures. Further studies with longer duration of follow up are required to conclude on the long term outcome of this these implants in unstable trochanteric fractures.

the JESS frame after callus becomes visible on radiograph and as pain allows. It is a cost effective treatment option in these patients where non operative treatment or internal fixation becomes difficult. As follow up period in our study is of short duration we could not comment on the limb length discrepancy in our patients. Further studies with similar treatment and longer duration of follow up are required to assess the long term outcome of JESS in these fractures.

CONCLUSION

Our study results shows fractures of the distal third tibial shaft and distal tibial physis with associated soft tissue injury can be well managed by JESS. In these patients who cannot be managed by cast application, JESS helps in the wound care and fracture stabilization without affecting the fracture healing process.

ABSTRACT

Background: Injuries around ankle and distal third of tibial shaft are among common paediatric bone trauma. Some of these cases are associated with soft tissue injury over the lower third of leg or around the ankle joint as tibia is subcutaneous on the anteromedial aspect. This study was conducted to know the outcome of these injuries with minimal invasive external fixation.
Methods: Eleven patients in the age group of 4-14 years were included in this study. All patients had closed fracture of distal third tibial shaft or injury of distal tibial physis with associated soft tissue injury. Joshi's external stabilization system was used to retain the reduction of fracture and appropriate wound care was taken. JESS was removed after radiological signs of fracture union.
Results: Patients were followed up for mean period of 8.9 month. After JESS fixation healing of wound occurred at an average of 12.45 day and external fixator was removed at 6-8 weeks period. Three patients had grade 1 pin tract infection which was controlled by local dressing. No patient had stiffness of ankle at the time of JESS removal. No limb length discrepancy was seen in any of the patients in this study at their final follow up.
Conclusions: JESS gives good results in fractures of distal tibial with associated soft tissue injury. It helps in better management of wound and fracture stabilization.

INTRODUCTION

Tibial and fibular shaft fractures are the third most common among long bones in children contributing up to 15% after radial/ulnar and femoral fractures.[1] Fifty to 70% of these fractures occur in distal third of tibia.[2] In children from 1 to 4 years of age group bicycle spoke injuries to tibia are common, whereas 4 to 14 years of age are due to sports and road traffic accidents.[2] Nine percent of fractures of tibia in children are open.[2]

These fractures are most commonly associated with concomitant fractures of the ankle. Fractures of the tibia constitutes up to 10-15% of all fractures in children and are also most common lower limb fractures in paediatric age group.[3]

Distal tibial and fibular physeal injuries account for 25% to 38% of all physeal fractures and are second most common to get injured among growth plate injuries.[4,5] Poland in his monograph (1898) pointed out that forces which result in ligament injury in adults causes fractures of the physis in children as ligaments are stronger than the physeal cartilage.[2] Distal tibial physeal fractures are classified according to Salter-Harris anatomical classification.

Closed fractures of tibial shaft in children are usually treated by non-operative methods. Open fractures and fractures with associated soft tissue injury requires operative fixation of fracture for proper wound care.[2] Distal tibial and fibular physeal fractures require accurate reduction and fixation to avoid future growth disturbance.

The aim of this study is to assess the role of Joshi's external stabilization system (JESS) in the management of these fractures associated with soft tissue injury

METHODS

From December 2013 to January 2016, 11 children with injury to the distal tibia and fibula with associated soft tissue injury were surgically managed by JESS. Institutional ethical committee clearance was taken for this study. All patients presented to emergency department with history of trauma to leg and associated wound over the ankle region. Patients were initially stabilized in the casualty department and radiograph of the involved leg was ordered after cleaning and dressing of the wound.

Patients below the age of 18 years with fractures of the distal third tibia and fibular shaft or distal tibial and fibular physeal injury with associated soft tissue injury over the fracture site were included in this study. Closed fractures of shaft of both bones of leg and closed undisplaced fractures of distal tibial and fibular physis without soft tissue injury and patients above 18 years of age were not included in the study.

Relevant patient data was collected after taking informed consent to participate in the study from the parent/guardian of the child. Surgical procedure and wound care process was explained to the attendant of the patient. Radiographs of all the patients were assessed for the fracture site, amount of displacement and type of growth plate injury in ankle fractures. Ankle fractures were classified according to Salter-Harris anatomic classification of physeal fractures.[6]

Patients were taken for surgery within 24 hours of injury after getting clearance from the paediatrician and anaesthetist. Under spinal anaesthesia thorough debridement and irrigation of the wound was performed. Fractures of the distal tibial metaphysis were reduced under image intensifier guidance and stabilized with two kirschner wires (K-wire) of 1.5 mm to 3 mm size both in the proximal and distal fragments as shown in Figure 1. During the surgery care was taken to avoid the wires passing through the injured soft tissue or wound. These wires were interconnected with JESS connecting rods on either side using JESS clamps. Patients with distal tibial physeal injury were also fixed with smooth pins or K-wires after accurate reduction of the fracture fragments under image intensifier. One or two K-wires were passed through the distal tibial epiphysis and physis up to the opposite cortex of metaphysis depending on the fracture pattern as given in Figure 2. Unstable fractures of the fibula after fixation of the tibia were fixed with an intramedullary K- wire. No fixation was done for stable fibular fractures.

In the postoperative period ankle movements were encouraged from day one. Appropriate antibiotics were given by intravenous route. Proper care of the wound and pin tracts were done to avoid infection. Radiographs were taken at 1 week, 3 weeks, and 6 weeks to see the fracture union and retention of reduction. After healing of the wound patients were encouraged partial weight bearing with JESS at 4 weeks or as the pain allowed. JESS was removed after radiological union of the fracture and care of pin tract wound was taken till they healed. Post JESS removal patients were followed up at 3 months and 6 months.

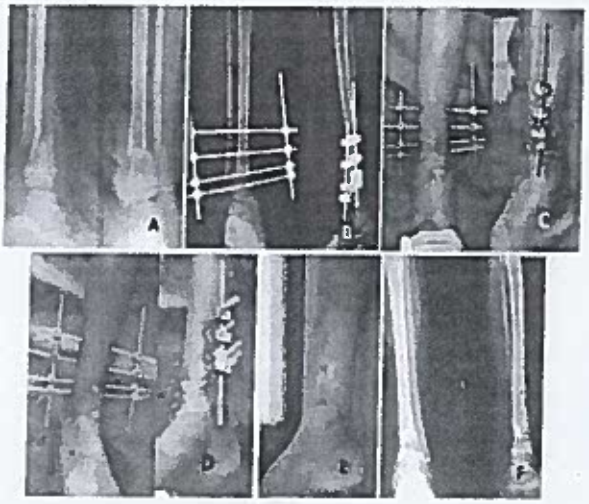

Figure 1: Distal tibial metaphyseal fracture with wound.
A) Pre-op, B) Post-op X-ray (C) Clinical picture of initial wound & (D) Healed wound, (E&F) After JESS removal.

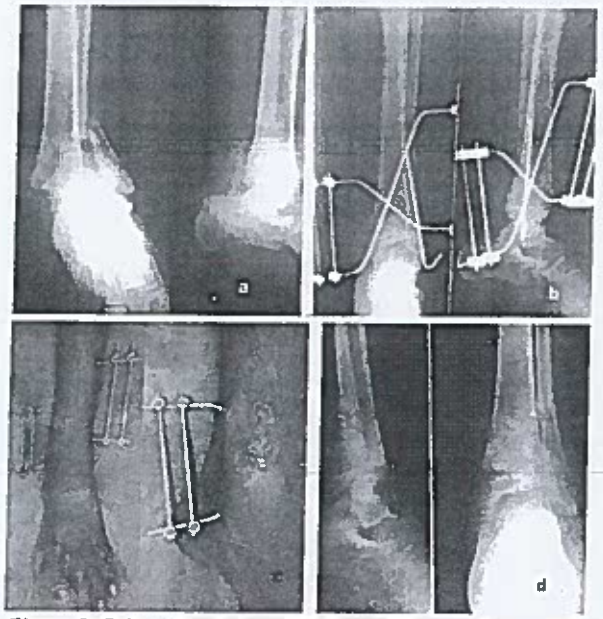

Figure 2: Salter-Harris type II injury with wound managed by JESS.

Data analyzed for type of fracture, wound healing period, duration of fracture union and complications.

RESULTS

This study included 11 patients aged between 5-14 years. All the patients had fractures of distal tibial metaphysis or epiphysis and distal fibula with soft tissue injury over lower part of leg and ankle joint. All the patients were managed by JESS apparatus after closed reduction of fracture with appropriate frames. Average age of the study population was 9.27±3.03 year. Males were predominant in this study with road traffic accident (RTA) being the frequent cause of injury. Four patients had fracture of distal metaphysis of the tibia and other seven had distal tibial physeal injury. No patients had any neurovascular injury. Other demographic data of the patients are as given in Table 1.

Table 1: Demographic data of the patients.

Variables	Number (%) (n=11)
Mean Age ± SD	9.27±3.03 year
Sex of the patients	
Male	8 (72.72%)
Female	3 (27.27%)
Fractures operated	
Right side	6 (54.54%)
Left side	5 (45.45%)
Mode of injury	
Road traffic accident	6 (54.54%)
Fall from height	4 (36.36%)
Fall of weight on leg	1 (9.09%)
Fracture type (distal tibial physis)	
Salter-Harris type 2	6 (54.54%)
Salter-Harris type 3	1 (9.09%)
Distal tibial metaphysis fracture	4 (36.36%)

Table 2: Results of JESS.

Variables	Mean ± SD	Range
Duration of wound healing	12.45 ± 3.88	6-21 Days
Partial weight bearing	5.09 ± 0.7	4-6 Weeks
JESS removal	6.63 ± 0.8	6-8 Weeks
Full weight bearing	7.09 ± 0.94	6-9 Weeks

Patients were followed up for an average of 8.9±2.38 months (6-12 months). Duration of wound healing ranged between 8-21 days in these patients with an average of 12.45 day. Time at which partial weight bearing was started ranged from 4 weeks to 6 weeks. JESS fixation was removed at an average of 6.63 week and full weight bearing was started at an average of 7.09 week as shown in Table 2. All the patients had radiological union at the time of full weight bearing. Three patients had grade-1 pin tract infection which healed with local care. No patients in the study had limb length discrepancy at their final follow up which ranged from 6 months to 12 months. All the patients had normal range of ankle movements after removal of the JESS.

DISCUSSION

Fractures around the ankle and distal third tibial shaft are common in pediatric age group. Incidence of distal tibial fibular physeal injuries account for 25-38% of all physeal fractures.[4] Another study reported that ankle fractures in children account for 5% of pediatric fractures and 15% of physeal injuries.[6] Physeal injuries are more common than ligament injuries in pediatric age group as ligaments are stronger than open physis.[6] Almost up to 58% of these distal tibial and fibular physeal injuries occurred during sports activities.[7,8] Incidence of physeal ankle fractures is more in male than in females.[9] Commonest age group for tibial physeal fractures is around 8-15 years.[9] Schurz et al found that an adduction trauma to the ankle being the common cause of injury followed by abduction trauma.[10]

Distal tibial physeal injuries require appropriate treatment otherwise which could lead to deformities and limb length discrepancy. Incidence of growth abnormalities is high in Salter-Harris type III and IV injuries and less in type II fractures.[9] Damage to the proliferative layer of cells in the growth plate may occur due to fracture passing through the physis in type III and IV lesions with high risk of growth disturbences.[11] Distal tibial physeal injuries require an absolute anatomical reduction by closed or open technique to decrease the rate of epiphysiodesis and related problems.[11]

Operative treatment is recommended in unstable fractures of distal tibial metaphysis and physis or when these fractures are associated with soft tissue injury.[2] When these fractures are associated with soft tissue injury over the lower part of leg and ankle, appropriate wound care becomes difficult task with plaster cast. External Fixator serves both the purposes of fracture stabilization and soft tissue healing with minimal added trauma to the initial injury. JESS can be used these children with convenient frames according to the fracture stability and type and stiffness of the JESS can be adjusted depending on the K-wire size used.[13] In elder children the axial stability of the JESS can be increased by using thicker K-wires. In JESS as we are using smooth pins in the bone, these can be passed through the physis and connected to the frame to give stable fixation to fracture.

In literature closed reduction and cast application of closed distal tibial fractures and management of open fractures by internal or external fixation is discussed in detail. Not much of literature available on distal tibial fractures with soft tissue injury. Our study was conducted to see the results of these fractures managed with minimal invasive external fixation with JESS. Wound healing is better with JESS fixation and soft tissue injuries resolve faster in these patients. Stiffness of the nearby joints does not occur as we can mobilize the joints earlier. Partial weight bearing can be started along with

Rapid decalcification technique using tissue floatation bath (TFB) in a tertiary care oncology centre

Abstract

Background: Decalcification of bone is a very important procedure in pathology especially in an oncology set up for proper staging, chemotherapy response or even in diagnosis of tumors. Objectives- To evaluate the use of tissue floatation bath (TFB) for rapid decalcification of mandibulectomy specimens in an oncology setup.

Materials and Methods: Bony specimens received at pathology department were sliced using bone saw and then placed in 10% formalin at 45 0 C for 4 hours. These sections were then kept overnight in 10% nitric acid at 45 0 C in TFB for decalcification. Decalcification was checked manually next day morning and if decalcification is complete, and then the tissue transferred to tissue processor for routine tissue processing.

Results: Decalcification in tissue floatation bath takes approximately 18-20 hours with better cytomorphological details as compared to routine decalcification process which takes around 7-8 days for complete decalcification.

Conclusion: Tissue floatation bath is a common instrument available in all laboratories performing histopathological examination. Staining quality is comparable and time required for decalcification is improved as compared to routine decalcification technique. It can be used as an alternative to the more expensive microwave technique which requires additional instrument and space. To the best of our knowledge this is the first study using tissue floatation bath for rapid decalcification process.

Introduction

Decalcification is a process of complete removal of calcium from bone, teeth and other calcified tissues. It is a very important routine procedure that is employed in nearly all histopathology laboratories but is a very time consuming process and may lead to delay in management of patients. Decalcification is performed to assure that the specimen is soft enough to allow cutting with the microtome knife, so that to avoid damage to tissue as well as to knife.

Decalcification is carried out by various agents which either form soluble calcium salts (acids) or by chelating the calcium ions[1]. Strong acids decalcify tissue faster but can cause deterioration of stainability of tissue section and it increases with acidity of solution and length of decalcification periods[2,3]. Several factors influence the rate of decalcification including concentration and volume of decalcifying agent, temperature at which reaction takes place, size of the specimen, and use of microwave and solution agitation[1]. Thus, the speed of decalcification can be fastened. More concentrated acidic solution and microwave can produce rapid decalcification but damages the morphology of the tissues[4,5]. High temperature can expedite the decalcification process but temperature of more than 60^0C can cause charring of tissues.[5]

Decalcification is particularly important in an oncology setup where it is essential for diagnosis of primary bone tumors and involvement of bone by external malignancy like squamous carcinoma or other tumors. It is also important to know the extent of bone involvement along with the knowledge of margin status. This helps in knowing the staging, completeness of surgery and need for further management like radiotherapy or chemotherapy. Many treatment protocols for bone tumors require a report on an entire slice/grid of resected bone to allow assessment of the benefit or otherwise of preoperative drug treatment.

These all requires a good cellular morphology and a quick result to allow rapid therapeutic intervention for optimal patient care.

Heating is also a method known to accelerate the decalcification process[1,6] and in this study we used tissue floatation bath instead of microwave for rapid decalcification of bone using heat as a source to reduce time of decalcification.

The aim of the present study was to evaluate and compare decalcification of bone by routine method and by using tissue floatation bath with special attention to duration of decalcification and nuclear details.

In India, oral squamous cell carcinoma is one of the most common malignancies and in our institute also we receive many mandibulectomy specimens for histopathological examination. Sections from underlying mandibular bone provide internal control to look for nuclear and cytoplasmic details of squamous carcinoma.

Many studies are there in literature evaluating the role of microwave in rapid decalcification[4-9], but to the best of our knowledge no study has described the role of TFB for the same.

Materials and Methods

This study was performed at pathology department of a tertiary care oncology centre in India. In this study we used TFB as a heat source for rapid decalcification on bony cut margin and underlying bone of mandibulectomy specimens. We also compared the decalcification using TFB with conventional decalcification method with special reference to duration of decalcification and nuclear details.

In this study, a total of twenty hemimandibulectomy specimens were studied. Twenty Sections each of anterior bony cut margin and underlying bone were taken. Bony tissues were sliced using bone saw with a uniform thickness of 2-3 mm and a parallel slice of bone from the same site was taken to prepare another set of specimens. One set of specimens (20 sections of anterior bony cut margins and 20 of underlying bone) was processed through routine decalcification and another set was kept in TFB for rapid decalcification. Thus, we ensured that the two sections under comparison were from the same bone and from the same site. This was done to eliminate bias from other factors that can affect the decalcification process like age and type of bone.

These tissues were then placed in 10% formalin for 4 hours in order to achieve proper fixation. After removing from formalin, these tissues were placed in running water for 30 minutes to remove excess formalin. After that tissues were kept in decalcifying solution (10% nitric acid).

In the routine decalcification method, tissues were placed in a decalcifying agent at room temperature with change of solution at regular intervals till the decalcification is completed. In the method using tissue floatation bath, bony tissues in cassettes are placed in the decalcifying agent in a metal container which was then kept overnight in preheated tissue floatation bath with temperature maintained at around 45^0C. The duration of decalcification and nuclear details of the tissue were noted, compared and tabulated. In both the methods, after completion of decalcification, the tissues were washed using distilled water for 30 minutes and were transferred to ammonia solution to neutralize the remaining acids. Tissues were then subjected to routine processing. Sections were then stained with hematoxylene and eosin stain and submitted for reporting. The stained sections of decalcified bone were assessed for the quality of staining and preservation of nuclear details.

Results

(Table 1) In this study, the average time required for decalcification was approximately 7-8 days by routine decalcification technique while with tissue floatation bath technique the time taken for decalcification reduced to 18- 20 hours for the same set of specimens.

The stained sections of the processed decalcified bone were assessed for the staining quality and preservation of the cytoplasmic and nuclear details. In our study the cellular architecture of the tissue was comparable in both techniques. Decalcification with TFB technique provides a better nuclear staining and nucleo- cytoplasmic differentiation of the stained section with a lesser shrinkage of tissue probably because of lesser duration of contact with the acid. Yellowishness of the stained section was also significantly reduced thus leading to better interpretation. Morphology of soft tissue squamous cell carcinoma was also better preserved then that with conventional methods.

Fig. 1: Showing a common tissue floatation bath showing a metallic container holding the decalcifying fluid

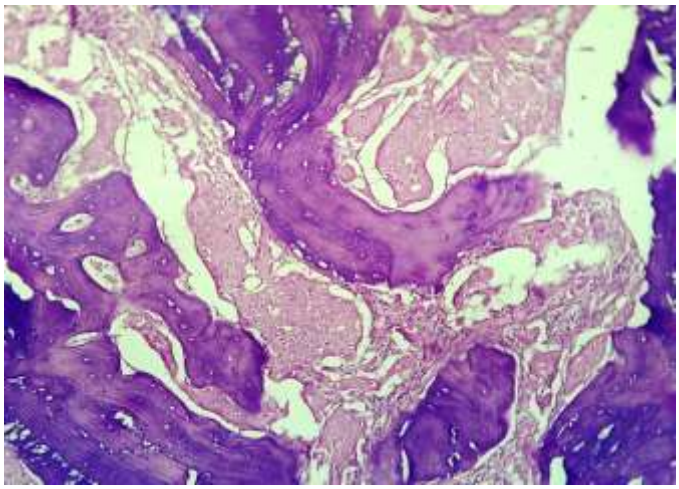

Fig. 2: Showing section of mandibulectomy showing bony trabeculae and a squamous carcinoma infiltrating the bone (100 X)

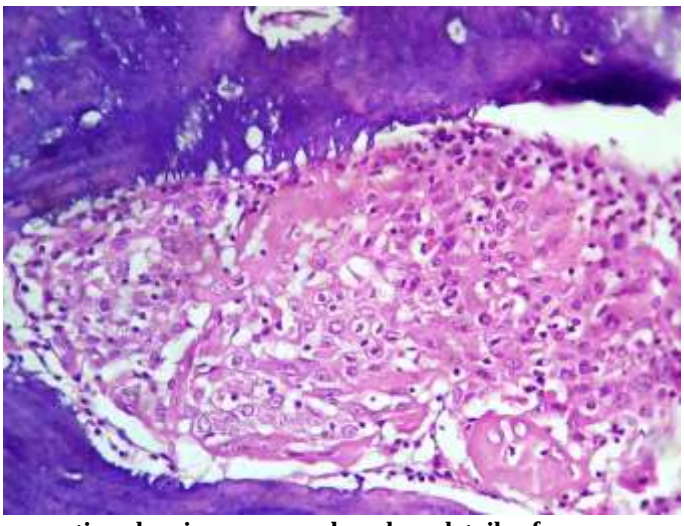

Fig. 3: High power of same section showing preserved nuclear details of squamous carcinoma and decreased eosinophilia (400 X)

Table 1: Comparison of cellular morphology of tissue processed by conventional and TFB method

Parameters	Routine method	TFB method
Yellowishness of tissue section	Present	Significantly reduced
Tissue shrinkage	Present	Less than routine method
Nuclear details	Average	Good
Cytoplasmic eosinophilia	Present	Reduced
Nucleo- cytoplasmic contrast	Blurred	Better
Decalcification time	8-10 days	1day

Discussion

Decalcification is a routine procedure and its aim is to remove calcium salts while preserving the normal architecture of the cells. Bones are one of the important specimen of decalcification in an oncology institute, but other specimens, such as calcified soft tissue tumors, calcified lymph nodes etc. also require this process.

Since the start of decalcification procedure, many studies were conducted for any advances in reagents or procedure with very little change in methodology. This is limited to some additional decalcification solutions and microwave-assisted decalcification. The duration of decalcification is very important for timely diagnosis and management of the patients. In this study we tried decalcification on mandibulectomy sections as they form a majority of specimens in an oncology institute and management of patient also depends on the fast comments on bony cut margins and status of underlying bones. Involvement of underlying bone by squamous carcinoma also requires adequate preservation of the tumor component. Thus, it is very essential to have a correct balance between speed and quality of processing so that ultimate goal of quality patient care is achieved.

Heat is known to expedite the rate of decalcification as it increases the rate of diffusion and increases rate of chemical reaction[9]. In a study performed by Verdenius et al[10] it was observed that time required for decalcification was reduced with increase in temperature. In a study done by Supriya Nikita Kapila et al[11], they have used hot air oven and magnetic stirrer for rapid decalcification process with significant reduction in time of decalcification and improvement in quality of staining. In our study also, there was shortening of time required for decalcification when tissues were continuously exposed to a controlled temperature of 45^0C. When comparing to conventional method of decalcification which require 7-8 days for complete decalcification, our method using TFB require only 18-20 hours for complete decalcification.

Various studies are in literature describing the role of microwave in rapid decalcification. In a study done by R Sangeeta et al[4], microwave was used as for expediting the decalcification process which takes around 2 days for condyles to get decalcified. Pitol et al[5] also mentioned the use of domestic microwave in decalcification with similar results as R Sangeeta et al. It was also suggested that domestic microwave cannot be effectively used for decalcification due to absence of temperature control and temperature beyond 60^0C can damage the tissue[9,12].

These all studies require a separate instrument for this process which require additional space and cost constraints. In our study we have used the tissue floatation bath which is present in nearly every histopathology laboratory which minimizes the requirement for a separate instrument. Also this instrument has an adjustable temperature control up to 110^0C which enables the adequate temperature control throughout the process. In our study it takes about 18-20 hours for decalcification process which is slightly better to that in above mentioned studies.

This instrument which is readily available in all laboratories, fitted with a temperature control provides a rapid decalcification which is comparable to other techniques in respect of duration and staining quality and can be used as an alternative to other methods for decalcification.

Conclusion

The TFB method decalcifies bony tissues much faster than the routine method and is available in nearly all histopathology laboratories. Tissue preservation and staining efficacy is comparable to routine decalcification. It is to emphasize that no separate instrument is required for decalcification process as in microwave technique especially at a tertiary care centre with a lesser workload.

Thus, the TFB is rapid technique as compared to routine methods and is cheaper and easily available technique then microwave with comparable staining quality and preservation.

To the best of our knowledge, this is the first study demonstrating the use of tissue floatation bath in rapid decalcification of bony tissues. Also this can be used for other calcified or bony specimens and further studies are required.

Conflicts of interest: There are no conflicts of interest.

Abstract

Background and Objectives: Pancytopenia is one of the most common indications for bone marrow (BM) examination. There are spectrums of condition involving the bone marrow (BM) that can present with pancytopenia and include malignant as well as benign diseases. The objective of this study is to evaluate the BM findings in cases of pancytopenia.

Materials and Methods: This was a retrospective study of 156 cases of pancytopenia presenting over a period of 3 years. Data were retrieved from laboratory and clinical records and were analysed.

Results: Out of 156 cases, the most common cause for pancytopenia in this study was megaloblastic anemia (25.6%), followed by acute leukemia (16%), hypoplastic marrow (14%), metastatic solid tumors (8.9%), myelodysplastic syndrome (MDS) (7.1%), lymphomas (5.7%), plasma cell dyscrasia(3.8%). Along with these there were many benign yet rare causes which may present with pancytopenia like Hemophagocytic syndrome (1.2%), Histoplasmosis (0.6%), Leishmaniasis (0.6%) and Gaucher's disease (0.6%). Bone marrow examination (combining both aspirate and biopsy) alone was sufficient in diagnosing 55% of cases, while remaining cases require additional details like clinical findings (for cases of MDS, viral infection, hypersplenism, autoimmune, septicemia) and special investigations like hemoglobin electrophoresis for hemoglobinopathy. In only 3.8% cases, BME was inconclusive.

Conclusion: BME is an important investigation in diagnostic work up of cases of pancytopenia. In majority of cases, it can provide an accurate diagnosis or at least can guide the approach towards diagnosis and management. Thus, it should be performed in all cases of persistent pancytopenia and should be evaluated in light of clinical details and supportive investigations.

Introduction

Pancytopenia is an important clinical entity which is defined as reduction in the number of all the three series (WBC's, RBC's and platelets) in peripheral blood[1].

Pancytopenia is a clinical outcome of many diseases that involve bone marrow either primarily or secondarily. Management of pancytopenia cases depends on the severity of pancytopenia and treatment of the underlying pathology[2].

There are various mechanisms for development of pancytopenia and this include reduced or ineffective hematopoiesis and increased destruction by either sequestration or destruction by antibodies[3].

In cases of pancytopenias, patient usually presents with clinical features attributable to decreased number of RBC's, platelets or WBC's i.e., pallor, easy fatiguability, bleeding, weight loss, or repeated infections leading to fever[4].

Bone marrow examination not only helps in final diagnosis but can also help in indicating the approach to diagnosis based on various parameters like cellularity (hypocellular or hypercellular), Blasts (for leukemias), abnormal cells (lymphoma, plasma cells, carcinoma cells, histiocytes), organisms (fungus, parasite), dysplastic changes in cells (MDS) or megaloblastic maturation.

Correlation with bone marrow biopsy is also important in cases where aspirate is hemodiluted or in hypocellular marrows. Biopsy also helps in many conditions which focally involve the bone marrow like metastatic carcinomas or lymphomas or tuberculosis.

This study is performed at a tertiary care centre and medical college in India and is intended to look at BM findings in cases of pancytopenia so that one should keep in mind various differentials that can present with pancytopenia.

Materials and Methods

This was a retrospective study performed at a tertiary care centre and medical college over a period of three years in Department of pathology. Laboratory data from all the cases who presented with pancytopenia (hemoglobin< 10gm/dl total leukocyte count < 4000/mm^3 and platelet count /150,000/mm^3) were retrieved. Clinical details were obtained from patient's case file and was tabulated, analyzed and correlated with that of laboratory parameters. Cases of

chemotherapy induced pancytopenia (whether benign or malignant) were excluded from this study. Bone marrow aspiration was performed from posterior superior iliac spine. Slides were prepared and stained with leishman stain. Biopsy was processed as per laboratory protocol for bone marrow. Special stains were performed wherever required.

Results

In our institute we receive a total of 610 bone marrow specimens over 3 year duration of which we studied around 156 cases who presented with pancytopenia (Table 1). Male: female ratio was 1.6:1 with 97 males and 59 females. The age of the patients ranged from 2 months to 70 years. Out of 156 cases of pancytopenia, 41 patients (26.3%) were in pediatric age group (<18 years) and remaining 115 patients (73.7%) were adults (>18 years).

Most common presentation (Table 2) was pallor (70.5%) followed by fever (30.1%), splenomegaly (23.1%), hepatomegaly (19.8%) and associated lymphadenopathy (17.3%) while only 5.7% cases were asymptomatic.

Peripheral smear findings (Table 3) in most of the cases show presence of anisocytosis (41%) followed by lymphocytosis (32.1%), nucleated red blood cells (31.4%), and poikilocytosis (20.5%). Blasts were seen in 15.4% cases.

Table 1: Bone marrow aspiration findings in pancytopenia (n= 156)

Diagnosis	Total number of cases				Total

Discussion

Pancytopenia is a common hematological finding seen in many diseases and diagnosis still remains a challenge for pathologist as well as to clinician. Accurate diagnosis is very crucial for management of patient. Bone marrow examination is very important investigation in patients of pancytopenia and should be looked carefully to achieve proper diagnosis. Even in the absence of a final diagnosis, BME can help clinician in approach to diagnosis and management of the patient.

In our study, out of total 610 cases of BME performed, 25.6% cases presented with pancytopenia which is slightly higher than that in literature.[5-7]

Male: Female ratio in our study was 1.6:1 which is comparable to some studies[6,8] while few study showed slightly female preponderance[9].

In this study most common isolated cause of pancytopenia was megaloblastic anemia which is comparable to many studies performed[8,10-13] while few studies found hypoplastic marrow as the most common cause of pancytopenia[6,14-16].

In a study[17], they found neoplastic diseases as most common cause of pancytopenia. In our study also, combined total of all neoplastic cases exceed that of megaloblastic anemia because this medical college has a separate cancer unit that caters predominantly to cancer patients and many cancers when involve bone marrow, presents with pancytopenia.

In our study second most common cause was acute leukemia which includes both acute myeloid and acute lymphoblastic leukemias. Blasts were seen in peripheral blood smears in 23 cases while two showed absence of blasts on PBS (aleukemic leukemia). These two cases turned out to be acute promyelocytic leukemia (APML) with few promyelocytes on PBS and around 80% promyelocytes and 10% blasts on BME. Out of 23 cases, 8 cases showed mildly reduced count with few blasts on PBS (5-10%) and bone marrow in all these cases show features of acute leukemia with > 50% blasts.

Hypoplastic marrow was 3rd most common cause and all these cases were confirmed on biopsy. Majority of these cases (20) show reduced count with predominantly lymphocytes on peripheral blood smears and similar findings on BME. The diagnosis was confirmed on bone marrow biopsy and was in correlation with aspirate findings.

In our study metastasis of solid tumors (Fig. 1) was seen as reason for pancytopenia in 14 cases with lung, breast and prostate as the most common site of primary in adults while in a single pediatric case ewing's sarcoma was the primary tumor producing pancytopenia. In most of these cases (10) peripheral blood showed circulating nucleated RBC's.

In this study, Myelodysplastic syndrome was found as a cause of pancytopenia in 11 cases, lymphoma infiltration in 9 cases and marrow plasmacytosis in 6 cases.

We found 2 cases of hairy cell leukemia presenting with pancytopenia and one was diagnosed outside as hypocellular marrow with marrow fibrosis on biopsy. He was referred to our hospital with worsening symptoms and marrow was repeated and showed hypocellular marrow with atypical lymphoid cells (Fig. 2). Flow cytometry was asked for and it showed features of Hairy cell leukemia. This is important to discuss that irrespective of myelofibrosis on biopsy, if atypical lymphoid cells are seen on aspirate; special investigations like flow cytometry must be performed as Hairy cell leukemia can frequently cause bone marrow fibrosis.

We found 2 cases presented to us with pancytopenia, persistent fever, splenomegaly. On laboratory work up one case showed blood culture positive for pseudomonas and other patient was a known case of carcinoma ovary with suspected metastasis to bone marrow in view of decreasing counts. Bone marrow from both these cases showed scattered histiocytic cells showing hemophagocytosis (Fig. 3). No metastasis was found in cases suspected of metastatic carcinoma. In view of significant histiocytes showing hemophagocytosis serum ferritin was asked for and was raised in both the cases. Thus, the final diagnosis was made as hemophagocytic syndrome (HPS) as these cases fulfilled 5 criteria of the hemphagocytic syndrome as mentioned in literature[18]. One patient succumbed to the disease irrespective of treatment. It is important to discuss that this is a very severe disease and prognosis and survival is very poor if treatment is not initiated early. Thus, patient with presence of hemophagocytosis in BM should be evaluated for HPS.

Other causes which we found as a cause of pancytopenia were viral induced, autoimmune (idiopathic thrombocytic purpura- 2cases and systemic lupus erythematosus- 1 case), myelofibrosis, septicemia, leishmaniasis (Fig. 4), histoplasmosis (Fig. 5), Hypersplenism, malaria, tuberculosis, Gaucher's disease (Fig. 6) and thalassemia.

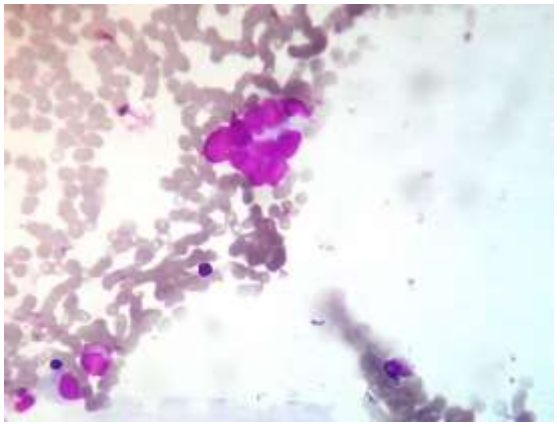

Fig. 1: Smears showing clusters of small round cells in a known case of small cell carcinoma (BM, 400x)

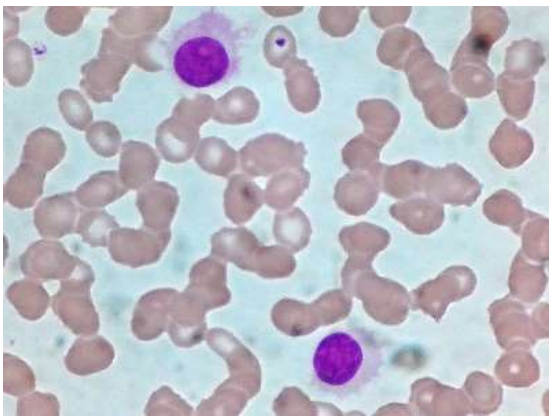

Fig. 2: Hypocellular marrow showing scattered atypical lymphoid cells with cytoplasmic projections (BM, 1000x)

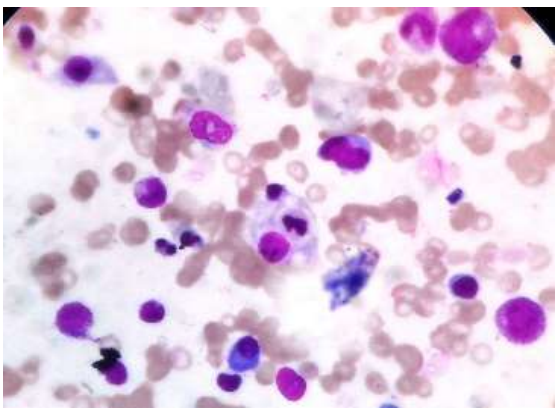

Fig. 3: Histiocytic cells showing phagocytosis of nucleated red blood cells (BM, 1000x)

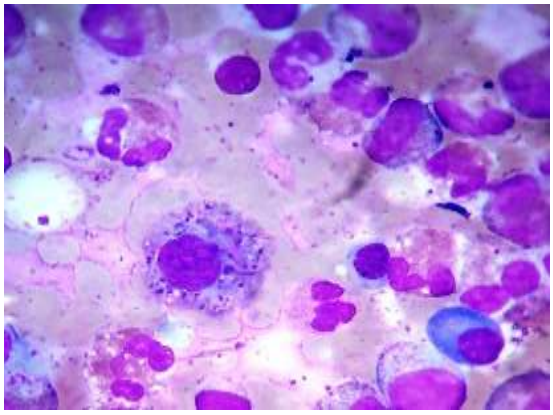

Fig. 4: Scattered and intra-cytoplasmic parasite consistent with leishmaniasis (BM, 1000x)

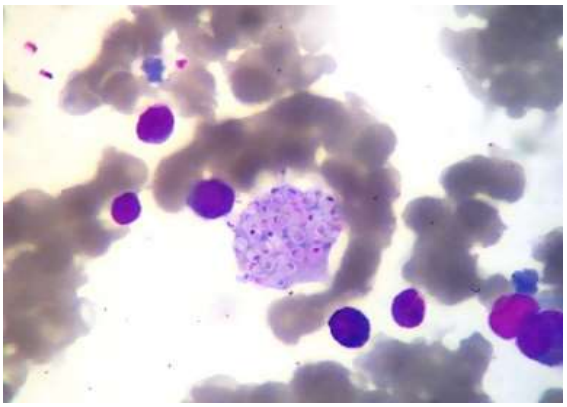

Fig. 5: Cytoplasmic fragment showing intracellular histoplasma organisms (BM, 1000x)

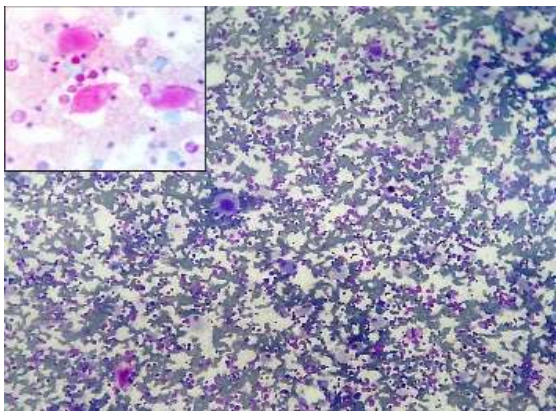

Fig. 6: Gaucher's cells with inset showing PAS positive intacellular accumulation (BM, 1000x)

Conclusion

Bone marrow examination is an important investigation to be performed in cases of pancytopenia. Diagnosis can be made in majority of cases and in few cases it can direct the clinician to approach the disease. Most common cause of pancytopenia are megaloblastic anemia, leukemias and lymphomas, hypoplastic marrow and metastasis. In addition, specific causes of pancytopenia (e.g. Hemophagocytic syndrome, storage disorders, Hairy cell leukemia, fungal or parasitic

infections) should be kept in mind as some of them can be life threatening. Correlation of clinical, peripheral smear finding and bone marrow aspirate findings are required to arrive at final diagnosis.

Distribution of ABO and Rh types in Voluntary Blood Donors in a Tertiary Care Center in a Southern District of Rajasthan

Manish Mewani[1], Shikha Goyal[1*], Pranveer Singh Rao[1], Princy Shinde[2]

[1]Assistant Professor; [2]Senior Demonstrator, Department of Pathology, Ananta institute of Medical Sciences and Research Centre, Rajsamand, Rajasthan

ABSTRACT

Background: *Despite the long list of several other blood groups discovered, the knowledge and distribution of ABO and Rh-D blood group are essential for blood transfusion purposes, population genetic study and healthcare planning.* ***Aims:*** *This study is aimed to determine the distribution pattern of the ABO and Rh blood groups among blood donors in Southern Rajasthan and compare it with other data from similar studies within and outside India. The importance of the study lies in maintaining the blood bank inventory so that no patient dies due to the deficient supply of blood.*
Methods: *It is a retrospective study carried out at blood bank, Ananta Institute of Medical Sciences and Research centre, Rajsamand, Rajasthan over a period of 2 years from January 1, 2016, to December 31, 2017. Blood group of the blood donors was determined by commercially available standard monoclonal antisera by test tube agglutination technique accompanied by reverse grouping.*
Results: *Out of 1142 subjects, 1117 (97.81%) were male and 25 (2.19%) were female subjects. 279 (24.43%) donors were voluntary and 863 (75.56%) donors were replacement donors. On studying the ABO blood group system, the most frequent group was B (33.97%) followed by O (31.96%), A (22.06%), and AB (6.91%) in blood donors while in Rh system, 1084 (94.92%) donors were Rh positive and 58 (5.07%) were Rh negative.* ***Conclusions:*** *The knowledge of distribution of blood group is very important for blood banks and transfusion services which play an important role in the patient's health care. The study has a significant implication regarding the inventory management of blood bank and transfusion services and will also throw light on the reasons of deficiency of a particular group in a particular area so that deficient group donors may be encouraged to donate more frequently.*

INTRODUCTION

Blood is a very important and life-saving component of the body and hence its transfusion for various ailments is a landmark for improving health. Timely transfusion of blood saves millions of lives.

In recent times, transfusion medicine has gained immense importance and the use of specific components of blood rather than whole blood has gained importance. But there has been a shortage of sufficient blood units. An increase of 10.7 million blood donations from voluntary unpaid donors has been reported from 2008 to 2013. In total, 74 countries collect over 90% of their blood supply from voluntary unpaid blood donors; however, 71 countries collect more than 50% of their blood supply from family/replacement or paid donors[1].

Human red blood cells contain on their surface a series of glycoproteins and glycolipids, which constitute blood group antigens. Development of these antigens is genetically controlled, inherited in a mandelian fashion.[2] Erythrocyte antigens are organized into more than 30 blood group systems by the International Society of Blood Transfusion.[3] The ABO blood group system was the first human blood group system to be discovered by Landsteiner in 1901.[4] Later Landsteiner and Wiener defined the Rh blood group in

1941.[5] Together these two systems have proved to be the most important, for blood transfusion purposes.

All human populations share the same blood group systems; although they differ in the frequencies of specific types. The incidence of ABO and Rh groups varies markedly in different races, ethnic groups, and socio-economic groups in different part of the world.[6]

Discovery of ABO blood group system opened the way for discoveries in the field of immunohaematology, blood transfusion among humans irrespective of their natives, unmatched pregnancy, legal medicine, anthropology and the discovery of other blood group systems.[7]

The ABO blood group system is divided into four blood types on the basis of presence or absence of A and B surface antigens. The blood groups are ABO and AB. ABO blood group system is important because of the fact that A and B are strongly antigenic and anti A and anti B are naturally occurring antibodies present in the serum of persons lacking the corresponding antigen. These antibodies are capable of producing intravascular hemolysis in case of incompatible transfusion.[8]

ABO and Rh blood groups are useful in blood transfusion practice, population genetic studies, analyzing population migration patterns as well as resolving certain medicolegal issues, for example, disputed paternity cases.[9]

Blood banks usually have a problem of ever-changing stock position and it being very difficult to predict the prevalence of a particular blood group at a particular time hence the knowledge of distribution of ABO and Rh blood group is essential for effective management of inventory, be it a facility of a smaller local transfusion service or a regional or national transfusion service.[10]

The present study was done to assess the prevalence of blood groups in the region and to compare the results with other studies conducted in India and elsewhere in the world and its multipurpose future utilities for the health planners.

METHODS

This study was carried out at blood bank, Ananta Institute of Medical Sciences and Research centre, Rajsamand, Rajasthan, during the 2 years period from 1 January 2016 to 31 December 2017. Total 1,142 donors were considered medically fit and accepted for blood donation during the study period.

All were of age between 18 and 60 years. After blood donation, blood group was determined by forward blood grouping (cell grouping) by test tube agglutination method. Commercially available standard antisera A, antisera B, and antisera D were used after validation at blood bank. Reverse blood grouping (serum grouping) was performed by test tube agglutination method with pooled known A, B, and O cell that are being prepared daily at the blood bank. Final blood group is confirmed only if both forward group (cell group) and reverse group (serum group) are identical. The donor blood group data were recorded on specially formed pro forma, tabulated, analyzed, and compared with the similar studies by other authors.

RESULTS

Total number of donors was 1,142. The voluntary and replacement donors constituted 24.43% and 75.56% respectively. The frequency of ABO and Rh blood groups was compared. In ABO system, our study shows the highest frequency of blood group “B” (35.72%), followed by “O” (33.8%), “A” (23.38%), and “AB” (7.09%). Incidence of Rh positive and Rh-negative donors was 94.92% and 5.07% respectively. Percentage of male and female donors was 97.81% and 2.18% respectively.

Table 1. Distribution of different types of blood donors according to sex and donation type (voluntary/replacement).

Donation type	Male	Female	Total	Percent of Total
Voluntary	261	18	279	24.43%
Replacement	856	7	863	75.56%
Total	1117	25	1142	
Percent of Total	97.81%	2.18%		

Table 2: Distribution of blood donors according to group.

DISCUSSION

Total 1,142 subjects were included in the study. Replacement donors (75.56%) were much more than voluntary donors (24.43%).

In ABO system, our study shows the highest frequency of blood group “B” (33.97%), followed by “O” (31.96%), “A” (22.06%), and “AB” (6.91%) (Table 3). Blood group frequency with respect to ABO with Rh positive was found to be in sequence of B > O > A > AB (Table 2) which is in accordance with other studies.[11,12] The frequency for ABO with Rhesus negative comes out to be in sequence of O > B > A > AB (Table 2) which matches with study done by Kaur et al[12] but is in contrast with study done by Garg et al[13]

where the sequence of B > A > O > AB was given. As observed in Table 3, these figures are similar to the other studies carried out in India.[11-21,23]

Many studies have suggested that outside India, "A" group is much more common than "B". The most common blood group in the studies conducted in Britain, the USA, Australia, Nigeria, and Saudi Arabia is "O" group followed by "A," "B," and "AB".[24-28] In a study from Nepal, "A" group was the most common followed by B, O, and AB.[22]

Rh negativity status was found to be 5.07% in our study (Table 4) which is in accordance with the studies conducted at other places in India and is in contrast with western studies[24,25] where it was reported to be as high as 15-17%.

Table 4: Percentage of male and female donors in and outside India

Great Britain [34]	45	55
USA [37]	54.5	45.5

It has been observed that female donors (2.18%) are very less compared to male donors (97.81%) (Table 1, 4). Similar results have been seen in many studies conducted in India [10,13,16,29,30,31,32] and some developing countries for example in Iran [34] and Nigeria [33]. This may be attributed to taboos related to blood and its loss, fear of blood donation, low level of awareness regarding the importance of blood donation, lack of motivation and increased deferral in female donors which are obviously accentuated in developing countries. In contrast, female donors show significant participation in developed countries.[34,35,36,37]

The significance of such studies which analyze the prevalence of blood groups is manifold. The group-wise availability of blood will eventually reflect the prevalence of blood group in the general population in that territory. It helps the doctor to plan the treatment of patients in a better way, for example, at the time of emergencies such as trauma, Rh incompatibility, and postoperative care.

This type of studies also allows blood banks to identify and maintain records of donors of blood groups which are rare in that particular area. In case of any unavailability during any emergency, the donor could be contacted and requested if he/she would like to donate in a good cause.

The data generated can be useful in population genetic studies giving useful information for instance, about population migration patterns. It may also prove important for other studies of various geographical regions of India which will be useful to health planners while making efforts to face the future health challenges in the particular region.

CONCLUSION

In conclusion, blood group 'B' was most common in the study followed by 'O', 'A' and 'AB'. Proportion of Rh positive donors was 94.92% while Rh negative was 5.07%. Blood donation by females was very low (2.18%) compared to males (97.81%) and it needs to be increased by improving health status of females and generating awareness about importance of blood donation.

These studies generate a database of blood groups at local and regional level. It is important to conduct similar studies in other regions in order to present a broader picture which can have significant implications for doctors, patients, transfusion services and health planners.

Distribution of ABO and Rh types in Voluntary Blood Donors in a Tertiary Care Center in a Southern District of Rajasthan

Manish Mewani[1], Shikha Goyal[1*], Pranveer Singh Rao[1], Princy Shinde[2]

[1]Assistant Professor; [2]Senior Demonstrator, Department of Pathology, Ananta institute of Medical Sciences and Research Centre, Rajsamand, Rajasthan

ABSTRACT

Background: *Despite the long list of several other blood groups discovered, the knowledge and distribution of ABO and Rh-D blood group are essential for blood transfusion purposes, population genetic study and healthcare planning.* ***Aims:*** *This study is aimed to determine the distribution pattern of the ABO and Rh blood groups among blood donors in Southern Rajasthan and compare it with other data from similar studies within and outside India. The importance of the study lies in maintaining the blood bank inventory so that no patient dies due to the deficient supply of blood.*
Methods: *It is a retrospective study carried out at blood bank, Ananta Institute of Medical Sciences and Research centre, Rajsamand, Rajasthan over a period of 2 years from January 1, 2016, to December 31, 2017. Blood group of the blood donors was determined by commercially available standard monoclonal antisera by test tube agglutination technique accompanied by reverse grouping.*
Results: *Out of 1142 subjects, 1117 (97.81%) were male and 25 (2.19%) were female subjects. 279 (24.43%) donors were voluntary and 863 (75.56%) donors were replacement donors. On studying the ABO blood group system, the most frequent group was B (33.97%) followed by O (31.96%), A (22.06%), and AB (6.91%) in blood donors while in Rh system, 1084 (94.92%) donors were Rh positive and 58 (5.07%) were Rh negative.* ***Conclusions:*** *The knowledge of distribution of blood group is very important for blood banks and transfusion services which play an important role in the patient's health care. The study has a significant implication regarding the inventory management of blood bank and transfusion services and will also throw light on the reasons of deficiency of a particular group in a particular area so that deficient group donors may be encouraged to donate more frequently.*

Keywords: *ABO, blood bank, Rhesus, blood donors*

INTRODUCTION

Blood is a very important and life-saving component of the body and hence its transfusion for various ailments is a landmark for improving health. Timely transfusion of blood saves millions of lives.

In recent times, transfusion medicine has gained immense importance and the use of specific components of blood rather than whole blood has gained importance. But there has been a shortage of sufficient blood units. An increase of 10.7 million blood donations from voluntary unpaid donors has been reported from 2008 to 2013. In total, 74 countries collect over 90% of their blood supply from voluntary unpaid blood donors; however, 71 countries collect more than 50% of their blood supply from family/replacement or paid donors[1].

Human red blood cells contain on their surface a series of glycoproteins and glycolipids, which constitute blood group antigens. Development of these antigens is genetically controlled, inherited in a mandelian fashion.[2] Erythrocyte antigens are organized into more than 30 blood group systems by the International Society of Blood Transfusion.[3] The ABO blood group system was the first human blood group system to be discovered by Landsteiner in 1901.[4] Later Landsteiner and Wiener defined the Rh blood group in

1941.[5] Together these two systems have proved to be the most important, for blood transfusion purposes.

All human populations share the same blood group systems; although they differ in the frequencies of specific types. The incidence of ABO and Rh groups varies markedly in different races, ethnic groups, and socio-economic groups in different part of the world.[6]

Discovery of ABO blood group system opened the way for discoveries in the field of immunohaematology, blood transfusion among humans irrespective of their natives, unmatched pregnancy, legal medicine, anthropology and the discovery of other blood group systems.[7]

The ABO blood group system is divided into four blood types on the basis of presence or absence of A and B surface antigens. The blood groups are ABO and AB. ABO blood group system is important because of the fact that A and B are strongly antigenic and anti A and anti B are naturally occurring antibodies present in the serum of persons lacking the corresponding antigen. These antibodies are capable of producing intravascular hemolysis in case of incompatible transfusion.[8]

ABO and Rh blood groups are useful in blood transfusion practice, population genetic studies, analyzing population migration patterns as well as resolving certain medicolegal issues, for example, disputed paternity cases.[9]

Blood banks usually have a problem of ever-changing stock position and it being very difficult to predict the prevalence of a particular blood group at a particular time hence the knowledge of distribution of ABO and Rh blood group is essential for effective management of inventory, be it a facility of a smaller local transfusion service or a regional or national transfusion service.[10]

The present study was done to assess the prevalence of blood groups in the region and to compare the results with other studies conducted in India and elsewhere in the world and its multipurpose future utilities for the health planners.

METHODS

This study was carried out at blood bank, Ananta Institute of Medical Sciences and Research centre, Rajsamand, Rajasthan, during the 2 years period from 1 January 2016 to 31 December 2017. Total 1,142 donors were considered medically fit and accepted for blood donation during the study period.

All were of age between 18 and 60 years. After blood donation, blood group was determined by forward blood grouping (cell grouping) by test tube agglutination method. Commercially available standard antisera A, antisera B, and antisera D were used after validation at blood bank. Reverse blood grouping (serum grouping) was performed by test tube agglutination method with pooled known A, B, and O cell that are being prepared daily at the blood bank. Final blood group is confirmed only if both forward group (cell group) and reverse group (serum group) are identical. The donor blood group data were recorded on specially formed pro forma, tabulated, analyzed, and compared with the similar studies by other authors.

RESULTS

Total number of donors was 1,142. The voluntary and replacement donors constituted 24.43% and 75.56% respectively. The frequency of ABO and Rh blood groups was compared. In ABO system, our study shows the highest frequency of blood group “B” (35.72%), followed by “O” (33.8%), “A” (23.38%), and “AB” (7.09%). Incidence of Rh positive and Rh-negative donors was 94.92% and 5.07% respectively. Percentage of male and female donors was 97.81% and 2.18% respectively.

Table 1. Distribution of different types of blood donors according to sex and donation type (voluntary/replacement).

Donation type	Male	Female	Total	Percent of Total
Voluntary	261	18	279	24.43%
Replacement	856	7	863	75.56%
Total	1117	25	1142	
Percent of Total	97.81%	2.18%

DISCUSSION

Total 1,142 subjects were included in the study. Replacement donors (75.56%) were much more than voluntary donors (24.43%).

In ABO system, our study shows the highest frequency of blood group “B” (33.97%), followed by “O” (31.96%), “A” (22.06%), and “AB” (6.91%) (Table 3). Blood group frequency with respect to ABO with Rh positive was found to be in sequence of B > O > A > AB (Table 2) which is in accordance with other studies.[11,12] The frequency for ABO with Rhesus negative comes out to be in sequence of O > B > A > AB (Table 2) which matches with study done by Kaur et al[12] but is in contrast with study done by Garg et al[13]

where the sequence of B > A > O > AB was given. As observed in Table 3, these figures are similar to the other studies carried out in India.[11-21,23]

Many studies have suggested that outside India, "A" group is much more common than "B". The most common blood group in the studies conducted in Britain, the USA, Australia, Nigeria, and Saudi Arabia is "O" group followed by "A," "B," and "AB".[24-28] In a study from Nepal, "A" group was the most common followed by B, O, and AB.[22]

Rh negativity status was found to be 5.07% in our study (Table 4) which is in accordance with the studies conducted at other places in India and is in contrast with western studies[24,25] where it was reported to be as high as 15-17%.

USA [37]	54.5	45.5

It has been observed that female donors (2.18%) are very less compared to male donors (97.81%) (Table 1, 4). Similar results have been seen in many studies conducted in India [10,13,16,29,30,31,32] and some developing countries for example in Iran [34] and Nigeria [33]. This may be attributed to taboos related to blood and its loss, fear of blood donation, low level of awareness regarding the importance of blood donation, lack of motivation and increased deferral in female donors which are obviously accentuated in developing countries. In contrast, female donors show significant participation in developed countries.[34,35,36,37]

The significance of such studies which analyze the prevalence of blood groups is manifold. The group-wise availability of blood will eventually reflect the prevalence of blood group in the general population in that territory. It helps the doctor to plan the treatment of patients in a better way, for example, at the time of emergencies such as trauma, Rh incompatibility, and postoperative care.

This type of studies also allows blood banks to identify and maintain records of donors of blood groups which are rare in that particular area. In case of any unavailability during any emergency, the donor could be contacted and requested if he/she would like to donate in a good cause.

The data generated can be useful in population genetic studies giving useful information for instance, about population migration patterns. It may also prove important for other studies of various geographical regions of India which will be useful to health planners while making efforts to face the future health challenges in the particular region.

CONCLUSION

In conclusion, blood group 'B' was most common in the study followed by 'O', 'A' and 'AB'. Proportion of Rh positive donors was 94.92% while Rh negative was 5.07%. Blood donation by females was very low (2.18%) compared to males (97.81%) and it needs to be increased by improving health status of females and generating awareness about importance of blood donation.

These studies generate a database of blood groups at local and regional level. It is important to conduct similar studies in other regions in order to present a broader picture which can have significant implications for doctors, patients, transfusion services and health planners.

ABSTRACT

Objective: the present study was conducted to assess the prevalence and cytological pattern of various metastatic cervical lymph nodes in the southern part of Rajasthan, India.
Material and Methods: The prospective study was conducted in a tertiary healthcare centre of southern Rajasthan, India during the period of 1 year from August 2018 to August 2019. 100 patients with cytologically diagnosed metastatic cervical lymph node were included in the study. Review of all cytological reports were done according to standard guidelines and the diagnosis was classified and correlated with patient age and sex to explore the pattern and association.
Results: Age of the patients' ranges from 29 to 70 years with the mean age of 54.16 years. Maximum patients (80%) were from the age group > 50 years. Among the 100 study participants, 83% were male and 17% were females (Male: Female ratio- 4.89:1). Primary site was known in 89% cases while primary was occult in 11% cases. Out of 89 cases of known primary, 32 cases had primary in oral cavity followed by 24 cases having primary in larynx. On cytological examination, squamous cell carcinoma was found to be the most common type of tumour type (71%) followed by Adenocarcinoma (20 %).
Conclusion: Fine needle aspiration cytology is an effective, economical and reliable method in diagnosing metastasis with good degree of certainty. Squamous cell carcinoma is most common type of metastatic tumour which commonly affects older individuals after the fifth decade with male preponderance.

Keywords: Metastasis, Carcinoma, Lymph Node, cytology, Cytology.

INTRODUCTION

Lymphadenopathy is a sign of inflammation, infections, primary or metastatic tumours. This is commonly seen involving the head, neck and inguinal region. [(1)] Carcinoma metastatic from the head and neck region is the most important of these and must remain prominent in the mind of the clinician. [(2)] Even though the cause of cervical lymphadenopathy may vary, enlarged cervical nodes in an elderly patient must be considered as metastatic until proved otherwise. [(3)]

Fine needle aspiration of neck lymph nodes is quick, safe, very cost effective and simple technique, well tolerated by the patients, without any complication, done on an outpatient basis and repeatable. India is eminently suited for this procedure. [(4)] Metastatic lesions confirmed by FNAC also give clue to the nature and site of primary. [(5)] A correct diagnosis helps in early management thus reducing mortality and morbidity. The present study was performed to know the prevalence of various metastatic cervical lymph nodes in our region. As there is paucity of literature on these matters from

our region, this study will highlight for the same the cytomorphological patterns of neck node metastasis.

MATERIAL AND METHODS

Nature of study and study population: The present study was a prospective study performed in the department of Pathology of Ananta Institute of Medical Sciences, Rajsamand, Rajasthan during the period of 1 year from August 2018 to August 2019. 100 slides of cytologically diagnosed metastatic cervical lymph nodes among the various suspected patients referred for FNAC were included in the present study.

Study period: 1 year from August 2018 to August 2019

Sample size: 100 cases of metastatic cervical lymph nodes

Procedure: A well informed and written consent was taken from all the study participants before starting the study. Approval from institutional ethical committee was also taken. Brief clinical history including age, sex, site, side were taken from all the participants and thorough clinical examination was also carried out. The FNAC was performed by experienced faculty using 20-24 gauze needles without local anaesthesia. Needle was inserted up to the desired depth into the lymph node and adequate quantity of cellular material was withdrawn. A minimum of two well labeled glass smears were prepared. The smears were air dried and stained with Romanowsky stain according to standard procedure. Review of all cytological reports were done according to standard guidelines and the diagnosis was classified and correlated with patient age and sex to explore the pattern and association. All the information collected from the results of present study was correlated with previous studies done in the similar field and results were compared & correlated.

Patients with the diagnosis other than metastatic lymph node and those who refused to give consent were excluded from the study.

RESULTS

100 patients with metastatic cervical lymph nodes were included in present study. Age of the patients ranges from 29 to 70 years with the mean age of 54.16 years. Maximum patients were from the age group > 50 years. (Table 1)

Table 1 Age wise distribution of the study participants

S.No.	Age-group	Number	Percentage
1	< 30 years	01	01
2	31-50 years	19	19
3	>50 years	80	80
	Total	100	100

Among the 100 study participants, 83% were male and 17% were females (Male: Female ratio- 4.89:1). Primary site was known in 89% cases while primary was occult in 11% cases. Out of 89 cases of known primary, 32 cases had primary in oral cavity followed by 24 cases having primary in larynx. (Table 2)

Table 2 Distribution of primary site of the metastatic tumour

S.no.	Primary site	Number of cases	Percentage
1	Oral cavity	32	35.99
2	Larynx	24	26.96
3	Oropharynx	11	12.35
4	Nasopharynx	7	7.86
5	Lung	7	7.86
6	Breast	6	6.74
7	Thyroid	1	1.12
8	Prostate	1	1.12
	Total	89	100%

On cytological examination, squamous cell carcinoma was found to be the most common type of tumour type (71%) followed by Adenocarcinoma (20 %). (Table 3)

Table 3 Cytological diagnosis of cervical lymph node metastasis.

S.No.	Tumour type	Number of cases	Percentage
1	Squamous cell carcinoma	71	71
2	Adenocarcinoma	20	20
3	Undifferentiated carcinoma	6	6
4	Small cell carcinoma	2	2
5	Follicular carcinoma	1	1
	Total	100	100

DISCUSSION

In present study, age of the patients' ranges from 29 to 70 years with the mean age of 54.16 years and maximum number of patients were from the age group > 50 years.

Similar results were obtained in similar studies done in the past. In a study performed by Mehrotra et al in 2005, the commonly affected age group was 50-60 years. [(6)] Ghartimagar et al studied the utility of FNAC in metastatic lymph node in 2011 and found that most commonly affected age group was > 60 years. [(4)] Similarly, in a study by Virendra T et al, the most commonly affected age group was 50-60 years. [(7)]

The male: female ratio in present study was 4.89:1. In the study by Virendra T et al the ratio was 4:1. [(7)]The ratio was 2.9: 1 in the study done by Bhattacharjee et al in 2006. [(8)] The male: female ratio was almost equal in another study done by Engzell et al in 1971 (1.07:1). [(9)]

The most common primary site for metastasis in present study was oral cavity (32%). Izhar N. Bhagwan (2007) and Karabi Kohar et al (2008) also found the oral cavity as the most common primary site for cervical lymph node metastasis. [(10, 11)] In a study performed in china by Chih Hsu et al in 1971, the most common site for cervical lymph node metastasis was nasopharyngeal carcinoma. [(12)] We all know; the incidence and mortality of nasopharyngeal carcinoma are highest in china because of their specific diet and genetic inheritance. In a study performed by Malika Afroz, the most common primary site was larynx. [(13)]

In present study, the most common type of tumour was squamous cell carcinoma (71%) followed by adenocarcinoma (20%). Other types were undifferentiated carcinoma (6%), small cell carcinoma (2%) and follicular carcinoma (1%).

In squamous cell carcinoma, tumour cells are seen arranged in sheets or scattered singly. The cells had dense cytoplasm with hyperchromatic nuclei owhile cynophilic cytoplasm with pyknotic nuclei in PAP stain. Necrotic material is often present in the background and keratinization may also be found.

In adenocarcinoma, the tumour cells are arranged in acinar or papillary arrangements or singly scattered. Cells are cuboidal to columnar with moderate amount of cytoplasm and pleomorphic nuclei with prominent nucleoli. Intracellular mucin secretion is present.

In undifferentiated carcinoma, there is pattern less solid, sheet like growth of tumour cells. There are no nests, papillae, glands, trabeculae or spindle pattern, no squamous or mucinous metaplasia, no or minimal neuroendocrine differentiation. In present study, the undifferentiated carcinomas were mainly from the nasopharynx.

Metastatic small cell carcinoma was seen in 2 cases of present study where the primary was found to be in lungs. In small cell carcinoma, the cells have scanty cytoplasm with large nuclei. Nuclei usually demonstrate the classical “salt and pepper” chromatin with indistinct nucleoli and frequent molding.

One case of metastatic follicular carcinoma with suspected primary in thyroid was also encountered in present study.

Squamous cell carcinoma has been found as the most common verity in other studies done in the past by Ustun et al, [(14)] Izhar N. Bhagwan [(10)] and Kiran Alam et al. [(15)] In contrary to our result, adenocarcinoma was the most common variety in a study performed by Ghartimagar D. et al. [(4)]

CONCLUSION

Fine needle aspiration cytology is an effective, economical and reliable method in diagnosing metastasis with good degree of certainty. Squamous cell carcinoma is most common type of metastatic tumour which commonly affects older individuals after the fifth decade with male preponderance. Unnecessary use of invasive methods like surgical biopsy can be avoided with the use of FNAC.

Abstract
The most common cancer among women in the urban Indian population is breast cancer and it is second only to cancer of the cervix in the rural population. Breast cancer is no longer seen as a single disease but rather a multifaceted disease comprised of distinct biological subtypes with diverse natural history, presenting a varied spectrum of clinical, pathologic and molecular features with different prognostic and therapeutic implications. One important aspect of the role of Pathology in the evaluation of breast cancer is biomarker testing, specifically the accurate assessment of the Estrogen receptor (ER), progesterone receptor (PR), and Her2 neu status of a patient's breast cancer. Biomarkers can be prognostic, predictive, or both. Prognostic biomarkers are independent measures of prognosis such that the presence or absence of the biomarker is associated with a patient's overall clinical outcome.

Keywords: Breast carcinoma, ER, PR, Her2 neu, triple negative

Introduction
Breast carcinoma is a malignant proliferation of the epithelial cells lining the ducts and lobules of breast. Breast cancer is the most common malignancy in women, affecting one in 12 in the western world. Advances in imaging techniques and the increased use of aspiration needle biopsy have greatly assisted preoperative evaluation of breast lesions; however, in a large proportion of cases, differentiation between benign and malignant lesions still rests on histologic examination. Currently, routine clinical management of breast cancer incorporates specific molecular markers; namely ER (Estrogen receptor), PR (progesterone receptor), Her 2 neu (human epidermal growth factor receptor 2 gene) that have been proven to provide therapeutic, predictive and prognostic value.

Aims and Objective
1. To analyse histomorphology and lymph node status in breast carcinomas.
2. To study Estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor 2 (Her2 neu) in all these breast carcinomas

Materials and methods
All the lumpectomy, simple mastectomy and modified radical mastectomy specimens of carcinoma breast submitted to the Department of Pathology in a tertiary care hospital in 1 year were enrolled. A total of 50 cases were included in this study. H&E sections from the tumour were analysed for histomorphology and corresponding tumour section was used for immunohistochemistry analysis of ER, PR and Her2neu.

Observation and results
The present study comprised of 50 cases of breast carcinoma over a period of 24 months. The age of the patients range from 32 to 77 years with a mean age of 51.10 years (SD 10.869).
Majority of patients were in age group of 40-49 years. Modified radical mastectomies (96%) comprised the maximum load of specimens received followed by small biopsies (4%).
Most of the lesions were in the Right breast (64%). The most common location of tumour was in upper outer quadrant with 22 cases (44%) followed by upper inner quadrant with 11

cases (22%). In our study, the size of the tumour ranged from 1 to 9 cm with majority of the tumours (50%) in the size range of 2 to 5 cm. Most common histologic type was Infiltrating Ductal Carcinoma (Not otherwise Specified) with 66% cases (Table 1) (Figure1). Majority of the cases were of Grade II with 39 (78%) cases (Table 2). Lymph node positivity was seen in 24 cases (48%) and in 4 cases (8%) more than 10 positive lymph nodes were found.

ER, PR, Her 2neu status (Figure 2-4)
The immunohistochemical analysis revealed 54% (27 cases) positivity for ER with Allred score of 3-8. Majority (62.96%) of the ER positive cases had the Allred score of 7 or 8. PR positive cases were 23 (46%) with Allred score of 7 or 8 in most of the positive cases. Her2 neu was positive in 11 (22%) cases. Equivocal score was seen in 3 (6%) cases.

Lymph node status and Allred score for ER: In 24 cases (48%) lymph nodes were involved in which 12 cases (50%) were ER negative (Allred Score: 0,2). Lymph nodes were not involved in 24 cases (50%) in which 13 cases (54%) had ER positivity (Allred score: 3-8) (Table 3). Significant association was noted with ER score and lymph node involvement (p value < 0.05).

Lymph node status and Allred score for PR: In 24 cases (48%) lymph node status was positive with 13 cases (54.2%) being PR negative. In lymph node negative cases, 10 cases (41.6%) were PR positive (Allred score 3-8) (Table 4).

Lymph node status and Her2 neu score: In 36 (72%) cases Her2 neu score was negative. In HER2 neu negative cases, lymph nodes were involved in 17 patients (47.22%). Equivocal status was seen in 3 cases in which 1 case was positive for lymph nodes. In 11 patients HER2 neu score was 3+ out of which 6 cases (54.5%) had lymph node involvement (Table 5).

Allred score for Pr with her2/NEU score
In 11 cases (22%) HER2/neu was positive in which 10 cases (90.9%) were negative for PR with Allred score of 0 or 2. HER2/neu score inversely correlated with the Allred Score for PR (Table 6). Pearson Chi Square test showed significant association between HER2 neu score and Allred score for PR.

Triple negative status and histologic grade: The study had 13 triple negative cases, of which 12 cases (92.3%) were grade II or grade III, thus emphasising that Triple negative status is associated with higher grade (Table 7).
Pearsons Chi Square test showed significant correlation among triple negative status and tumour grade (p value < 0.05).

Discussion

Age: The age range of present study with mean age of 51.10 years was comparable with various other studies (Table 8).

Laterality: The present study had majority of tumours in the right breast while the studies by Sofi *et al.* and Nisa *et al.* have left predominance. (Table 9)

Tumour Size: In the present study the size of tumour ranged from 1 to 9 cm. The mean tumor size was 3.52 cm and is comparable to the studies by Mudduwa *et al*. [1] and Sofi *et al*. [2] (Table 10). Also it is noted in the present study that 72% of cases showed more than 2 cm tumor size which is similar to the results observed by Bhagat Vasudha *et al.* [3] (91.38%), Azizun *et al.* [4] (88%), Moses *et al.* [5] (91.6%) and Mona *et al.* [6] in their study. While study from western country, Adedayo *et al.* [7] showed 71.4% cases with ≤ 2cm size, this could be due to early cancer detection programs. In India owing to the lack of awareness of this disease and absence of a breast cancer screening program, the majority of breast cancers are diagnosed at a relatively advanced stage. In our study 14.3% of tumours which were less than 2 cm in size showed HER2/neu positive staining, 20% cases in the size range of 2-5 cm were HER2/neu positive and 36.4% cases in which tumour size was more than 5 cm were HER2/neu positive. Significant association between increasing tumor size and HER-2/neu expression was seen in our study. Tumors larger than 2 cm size had higher rates of Her-2/neu expression than those of tumors less than 2 cm size. Similar result was observed by Bhagat *et al.* [3] in their study.

Histologic type: The most common histologic type in the present study was IDC-NOS which is comparable to the findings of other studies (Table11).

Tumour grade: The most common tumour grade in the present study was grade II with 78% cases followed by grade II with 16% cases. This was similar to findings by Sofi *et al.* [2] and Ayadi *et al*. (Table 12).

Lymph node status: In 24 (48%) cases lymph nodes were positive for metastasis. In 2 cases lymph nodes were not retrieved. Lymph nodes were not involved in 24 (48%) cases. In the studies by various authors like Zubair Ahmed *et al*. [8], Mudduwa *et al*. [1]., Seho Park *et al*. [9], Lobna Ayadi *et al*. [10] and Lokuhetty [11] documented lymph nodes positive for metastasis as 74.77%, 57.7%, and 27.8%, 65% and 41% respectively.

ER/PR and HER2/neu status: Comparison of ER/PR and HER2/neu status in various studies is shown in the table 13**.** Out of total 50 cases, 22 cases (44%) showed positive staining for both ER and PR and 21 cases (42%) were negative for both ER and PR. Our findings were in concordance with study of R. Kumawat [12], who demonstrated 33% cases showed positive staining for both ER and PR while 45% cases showed negative staining for both estrogen and progesterone receptors. The negative ER PR status in IDC-NOS was comparable to study by Kumavat *et al.* [12].

HER2/neu score and Histologic Type: We compared our results with previously published international data. In the Sloan-Kattering study HER-2 positivity was limited to infiltrating breast carcinoma of the ductal and lobular morphology. None of the special type carcinomas like mucinous, medullary or papillary showed HER-2 positivity. These findings were similar to our study.

Histologic Grade with ER/PR and HER2/neu expression: The comparison of molecular marker expression in different studies are given in the table 14. Our findings were in concordance with Bird P *et al*. [13] who demonstrated that increasing tumour grade is associated with decreased PR expression

Triple Negative Breast Carcinoma (TNBC): The present study had 26% of triple negative breast carcinomas (TNBC). A major proportion (30.7%) of TNBC had tumour size >5cm as compared to 18.91% in other cases. The finding that *TNBC present with larger size* compared to other group is consistent with findings by Bauer *et al*. [14], Li *et al*. [15], Somali *et al*. [16]

Also the rate of node positivity was found in TNBC was high (53.84%) compared to node positivity in other group of carcinomas (45.94%). This is consistent with findings of Bauer *et al*, Li *et al*. The majority of TNBC were of *grade III*, the finding being consistent with Carey *et al*. [17], Bauer *et al*. [14], Somali *et al*. [16].

There are conflicting reports in literature regarding lymph node status in TNBC. While some publication report a higher rate of node positivity (Bauer *et al*. 2008; Li *et al*. 2013) [14, 15] Some report node negativity more common in TNBC (Foulkes *et al*, 2003; Cheang *et al*., 2008; Somali *et al*. 2013) [18, 19, 16]. In our study a high rate of node positivity was found in TNBC compared to other group (53.84% vs 45.94%). Comparing the histological subtypes, IDC NOS comprised maximum number of cases in both the study groups (61.53% vs 67.56%). Similar results were observed in other studies (Carey *et al*. 2006; Somali *et al*. 2013) [17, 16].

Conclusion

The study of ER, PR and HER2 neu expression in breast carcinomas by IHC is a very important diagnostic tool in deciding the treatment strategy and the prognosis. The study throws a light on lack of adequate screening programs and awareness regarding breast carcinoma in India compared to western countries. The study establishes a significant correlation between lack of estrogen receptors and lymph node involvement and also that expression of HER2 neu receptors are inversely related to the expression of progesterone receptors. Triple negative status of tumours significantly associated with higher tumour grade and tumour size.

ABSTRACT

Objective: the present study was conducted to assess the prevalence and cytological pattern of various metastatic cervical lymph nodes in the southern part of Rajasthan, India.
Material and Methods: The prospective study was conducted in a tertiary healthcare centre of southern Rajasthan, India during the period of 1 year from August 2018 to August 2019. 100 patients with cytologically diagnosed metastatic cervical lymph node were included in the study. Review of all cytological reports were done according to standard guidelines and the diagnosis was classified and correlated with patient age and sex to explore the pattern and association.
Results: Age of the patients' ranges from 29 to 70 years with the mean age of 54.16 years. Maximum patients (80%) were from the age group > 50 years. Among the 100 study participants, 83% were male and 17% were females (Male: Female ratio- 4.89:1). Primary site was known in 89% cases while primary was occult in 11% cases. Out of 89 cases of known primary, 32 cases had primary in oral cavity followed by 24 cases having primary in larynx. On cytological examination, squamous cell carcinoma was found to be the most common type of tumour type (71%) followed by Adenocarcinoma (20 %).
Conclusion: Fine needle aspiration cytology is an effective, economical and reliable method in diagnosing metastasis with good degree of certainty. Squamous cell carcinoma is most common type of metastatic tumour which commonly affects older individuals after the fifth decade with male preponderance.

Keywords: Metastasis, Carcinoma, Lymph Node, cytology, Cytology.

INTRODUCTION

Lymphadenopathy is a sign of inflammation, infections, primary or metastatic tumours. This is commonly seen involving the head, neck and inguinal region. [(1)] Carcinoma metastatic from the head and neck region is the most important of these and must remain prominent in the mind of the clinician. [(2)] Even though the cause of cervical lymphadenopathy may vary, enlarged cervical nodes in an elderly patient must be considered as metastatic until proved otherwise. [(3)]

Fine needle aspiration of neck lymph nodes is quick, safe, very cost effective and simple technique, well tolerated by the patients, without any complication, done on an outpatient basis and repeatable. India is eminently suited for this procedure. [(4)] Metastatic lesions confirmed by FNAC also give clue to the nature and site of primary. [(5)] A correct diagnosis helps in early management thus reducing mortality and morbidity. The present study was performed to know the prevalence of various metastatic cervical lymph nodes in our region. As there is paucity of literature on these matters from

our region, this study will highlight for the same the cytomorphological patterns of neck node metastasis.

MATERIAL AND METHODS

Nature of study and study population: The present study was a prospective study performed in the department of Pathology of Ananta Institute of Medical Sciences, Rajsamand, Rajasthan during the period of 1 year from August 2018 to August 2019. 100 slides of cytologically diagnosed metastatic cervical lymph nodes among the various suspected patients referred for FNAC were included in the present study.

Study period: 1 year from August 2018 to August 2019

Sample size: 100 cases of metastatic cervical lymph nodes

Procedure: A well informed and written consent was taken from all the study participants before starting the study. Approval from institutional ethical committee was also taken. Brief clinical history including age, sex, site, side were taken from all the participants and thorough clinical examination was also carried out. The FNAC was performed by experienced faculty using 20-24 gauze needles without local anaesthesia. Needle was inserted up to the desired depth into the lymph node and adequate quantity of cellular material was withdrawn. A minimum of two well labeled glass smears were prepared. The smears were air dried and stained with Romanowsky stain according to standard procedure. Review of all cytological reports were done according to standard guidelines and the diagnosis was classified and correlated with patient age and sex to explore the pattern and association. All the information collected from the results of present study was correlated with previous studies done in the similar field and results were compared & correlated.

Patients with the diagnosis other than metastatic lymph node and those who refused to give consent were excluded from the study.

RESULTS

100 patients with metastatic cervical lymph nodes were included in present study. Age of the patients ranges from 29 to 70 years with the mean age of 54.16 years. Maximum patients were from the age group > 50 years. (Table 1)

Table 1 Age wise distribution of the study participants

S.No.	Age-group	Number	Percentage
1	< 30 years	01	01
2	31-50 years	19	19
3	>50 years	80	80
	Total	100	100

Among the 100 study participants, 83% were male and 17% were females (Male: Female ratio- 4.89:1). Primary site was known in 89% cases while primary was occult in 11% cases. Out of 89 cases of known primary, 32 cases had primary in oral cavity followed by 24 cases having primary in larynx. (Table 2)

Table 2 Distribution of primary site of the metastatic tumour

S.no.	Primary site	Number of cases	Percentage
1	Oral cavity	32	35.99
2	Larynx	24	26.96
3	Oropharynx	11	12.35
4	Nasopharynx	7	7.86
5	Lung	7	7.86
6	Breast	6	6.74
7	Thyroid	1	1.12
8	Prostate	1	1.12
	Total	89	100%

On cytological examination, squamous cell carcinoma was found to be the most common type of tumour type (71%) followed by Adenocarcinoma (20 %). (Table 3)

Table 3 Cytological diagnosis of cervical lymph node metastasis.

S.No.	Tumour type	Number of cases	Percentage
1	Squamous cell carcinoma	71	71
2	Adenocarcinoma	20	20
3	Undifferentiated carcinoma	6	6
4	Small cell carcinoma	2	2
5	Follicular carcinoma	1	1
	Total	100	100

DISCUSSION

In present study, age of the patients' ranges from 29 to 70 years with the mean age of 54.16 years and maximum number of patients were from the age group > 50 years.

Similar results were obtained in similar studies done in the past. In a study performed by Mehrotra et al in 2005, the commonly affected age group was 50-60 years. [(6)] Ghartimagar et al studied the utility of FNAC in metastatic lymph node in 2011 and found that most commonly affected age group was > 60 years. [(4)] Similarly, in a study by Virendra T et al, the most commonly affected age group was 50-60 years. [(7)]

The male: female ratio in present study was 4.89:1. In the study by Virendra T et al the ratio was 4:1. [(7)]The ratio was 2.9: 1 in the study done by Bhattacharjee et al in 2006. [(8)] The male: female ratio was almost equal in another study done by Engzell et al in 1971 (1.07:1). [(9)]

The most common primary site for metastasis in present study was oral cavity (32%). Izhar N. Bhagwan (2007) and Karabi Kohar et al (2008) also found the oral cavity as the most common primary site for cervical lymph node metastasis. [(10, 11)] In a study performed in china by Chih Hsu et al in 1971, the most common site for cervical lymph node metastasis was nasopharyngeal carcinoma. [(12)] We all know; the incidence and mortality of nasopharyngeal carcinoma are highest in china because of their specific diet and genetic inheritance. In a study performed by Malika Afroz, the most common primary site was larynx. [(13)]

In present study, the most common type of tumour was squamous cell carcinoma (71%) followed by adenocarcinoma (20%). Other types were undifferentiated carcinoma (6%), small cell carcinoma (2%) and follicular carcinoma (1%).

In squamous cell carcinoma, tumour cells are seen arranged in sheets or scattered singly. The cells had dense cytoplasm with hyperchromatic nuclei owhile cynophilic cytoplasm with pyknotic nuclei in PAP stain. Necrotic material is often present in the background and keratinization may also be found.

In adenocarcinoma, the tumour cells are arranged in acinar or papillary arrangements or singly scattered. Cells are cuboidal to columnar with moderate amount of cytoplasm and pleomorphic nuclei with prominent nucleoli. Intracellular mucin secretion is present.

In undifferentiated carcinoma, there is pattern less solid, sheet like growth of tumour cells. There are no nests, papillae, glands, trabeculae or spindle pattern, no squamous or mucinous metaplasia, no or minimal neuroendocrine differentiation. In present study, the undifferentiated carcinomas were mainly from the nasopharynx.

Metastatic small cell carcinoma was seen in 2 cases of present study where the primary was found to be in lungs. In small cell carcinoma, the cells have scanty cytoplasm with large nuclei. Nuclei usually demonstrate the classical “salt and pepper” chromatin with indistinct nucleoli and frequent molding.

One case of metastatic follicular carcinoma with suspected primary in thyroid was also encountered in present study.

Squamous cell carcinoma has been found as the most common verity in other studies done in the past by Ustun et al, [(14)] Izhar N. Bhagwan [(10)] and Kiran Alam et al. [(15)] In contrary to our result, adenocarcinoma was the most common variety in a study performed by Ghartimagar D. et al. [(4)]

CONCLUSION

Fine needle aspiration cytology is an effective, economical and reliable method in diagnosing metastasis with good degree of certainty. Squamous cell carcinoma is most common type of metastatic tumour which commonly affects older individuals after the fifth decade with male preponderance. Unnecessary use of invasive methods like surgical biopsy can be avoided with the use of FNAC.

Pattern and Prevalence of Congenital Malformation of Fetus: Autopsy Based Study

Seemant Kumar Saini[1], Matariswa Samanta[2], DR Mathur[3], Anna Purna Mathur[4]

Abstract

Introduction: Autopsy is an important aspect of clinical service, providing clinicians with critical feedback regarding diagnostic accuracy, therapeutic efficacy, and medical complication [1]. Rajasthan has reportedly the second Indian state having highest number of child marriages in the country with more than 60 percent of girls getting married before 18 [1]. The practice of child marriage is common in Rajasthan. Along with cultural incest marriage leads to one most important causes of fatal anomalies. Early diagnosis of life threatening congenital malformation can pave the way for surgical correction or palliation of these infants [1].

Material and Method: We studied 217 cases of fetal autopsies from January 2017 to October 2018 duration of one year retrospective study. Purpose of study is pathological and legal correlation in aspect of M:F ratio, age of termination of pregnancy, fetal anomalies & its pattern In Pacific Institute of Medical Sciences (PIMS) and M.R. Medical College, Gulbarga, Karnatka.

Results: Total fetal autopsies done are 217, out of which 51 are anomalous.Among them 22 are male and 28 are female babies and 1 sex is not determined {ambiguous}. In our study M:F ratio is 1:1.35. Most common cause of death found in autopsy examination is meconium aspiration in male fetus and placental insufficiency in female fetus. And mean age of gestation is 29 week and 30 weeks respectively. Mean age of the mother is 29 years.

Conclusion: Fetal autopsies provide us an important information about pattern of anomalies, their incidence and cause of death in relation with sex and age of fetus, maternal age, along with socio-economical status. Legal implications regarding fetal autopsies is still a field of interest.

Keywords: Fetal Autopsy: Fetal Anomalies: Legal Aspects.

Introduction

Fetal autopsy includes external, internal and histopathological examination of dead fetus along with placental examination [2].

There are two types of fetal autopsy.

1. Medico-legal autopsy
2. Academic autopsy

Medico legal Autopsy– is conducted on requisition of police under section Crpc -174 to know the cause of death, age, sex and viability of fetus for which police inquest& panchnama is required [2].

Academic Autopsy / Clinico-pathological Autopsy– is conducted on request of obstetrician, pediatrician, radiologist or family members of fetus to know the cause of congenital malformation if any and cause of repeated abortions, where in the detail pre and post natal history of mother and consent of parents /relatives with the collaboration of concerned department is necessary [2]. Placental examination is done to know the cause of death to certain extent and placental pathology explains the cause of prematurity.

In our study we performed 217 cases of fetal autopsy to rule out cause of death and associated anomalies, which is helpful in future family planning for couples and improvement of management of anomalous babies

Etiological diagnosis in unexplained fetal deaths is possible with detailed evaluation of fetus. Fetal autopsy is confirmative in 28.6-89%, diagnostic in 10-38%; it provided additional information in 3.9-24% cases; it changed the predicted probability in 18% cases In addition, the data pertaining to demography, socio-economic status, and maternal health is helpful to pinpoint the factors behind the occurrence of fetal loss.

Congenital anomalies were estimated to be the fifth largest cause of neonatal deaths in India after preterm births (34.7%), intrapartum complications (19.6%), pneumonia (16.3%) and neonatal sepsis (15%) Despite this ranking, in absolute numbers, congenital anomalies were estimated to contribute to 60699 neonatal deaths in India in 2013, which accounted for the highest global burden of neonatal mortality due to congenital anomalies India lacks national birth defects surveillance, indicating that there is no data on the magnitude of congenital anomalies in the country [7,8]. Thus, systematic data on the magnitude of congenital anomalies, the most prevalent types of congenital anomalies, their healthcare impact and their impact on neonatal health are required, especially as India has announced a program me for the management of children born with selected birth defects like cleft palate lips etc. [9,10].

Materials and Method

We studied 217 cases The present study of congenital anomalies in fetal and neonatal deaths was done at PIMS. Study conducted over a time period of 8 month from January 2017 to october 2018. Consent for autopsy in requested compassionately, respectfully and was fully informed. Autopsy was within the scope of the autopsy permit and all the legal requirements are met before it is conducted. The dissecting instruments required for fetal and neonatal (perinatal) autopsy are small scissors and forceps and scalpels. The autopsy protocol was including space for recording specific measurements and norms for particular gestational ages.

Measurements

The crowns heal length (CHL) and crown rump (CRL) length determined to the nearest 0.5 cm. Chest and abdominal circumferences were taken at the level of the nipple and umbilicus respectively. Both limb measurements has been taken. The metric documentation of changes in the face is often a valuable component of the autopsy. So the distances between the inner canthi and outer canthi, nasal height and width, philtrum height, mouth width and ear length are obtained and compared with published norms. Weights: Scales accurated to 0.1 gm.in perinatal specimens. All major organs weighed (i.e. thymus, heart, lungs, liver, spleen, kidney, adrenal glands, brain and placenta) and the date recorded in the autopsy protocol along with expected values. Photographs were taken which provide indisputable evidence of findings and study of dysmorphic face images, for important diagnostic information [3].

Inclusion and exclusion criteria

The present study included dead fetus and neonates with gestational age 18 to 40 weeks of intra uterine life. All fetuses of gestational age <12 weeks and all neonates above 7 days of age were excluded from the study. Autopsy was performed by standard technique adopted by Edith L. Potter.

Procedure

1-External examination

Done for inspection of cyanosis, injuries and maceration, skin lesions, all major and minor developmental anomalies were described. The y shaped incision was taken which extend from the anterior aspect of each shoulder to the xiphoid process. Umbilical vein examined for signs of inflammation, vernix, rupture (or) thrombus. The two umbilical arteries are examined and inspected in their entirety. The arteries and urachus examined for patency and the arteries for hemorrhage (or) thrombosis. Single umbilical artery was an important anomaly noted. The autopsy protocol included the removal of thoracic, cervical, abdominal and pelvic organs en block and subsequently dissected into organ blocks [3].

2- Internal examination

All internal organs position and size and weight were examined. The internal genitalia are inspected. As the testis will be undescended in younger fetuses, are removed with abdominal contents. Prior to opening of the pleural cavities

the possibility of pneumo thorax is ruled out. on entering the chest each cavity inspected for fluid. Each lung was examined for developmental changes carefully. The integrity and tension of the pericardium are ascertained and the pericardial cavity is looked for the presence of free gas (or) fluid and fibrinous deposition. Heart examined in situ, while anatomic relationship with structures were intact, inspected externally and internally, in a systematic fashion that follows the flow of blood. All major veins and arteries were examined. The diagnosis of premature closure of foramen ovale if any are noted. The configuration of tricuspid valve, right ventricle, and main pulmonary artery were studied. The endocardium, myocardium, and configuration of trabeculae, pectinate and papillary muscles and chordae tendineae were examined. After opening the left part of heart, the interior of the left atrium [3] pulmonary venous orifices, mitral valve and left ventricle were inspected, followed by examination of the aortic valve and ascending aorta All other organs were removed en bloc by the rokitansky methods of evisceration. Neck structures trachea and esophagus were examined. The scalp, fontanels, and cranial sutures were examined by palpation and any changes were documented. The fontanels, sutures, and glia were examined and any changes were documented. brain has been exposed and examined in situ. Then the brain was removed and examined on all sides and placed in fixative. Attention to the cranial base and dural sinuses was given [3].

3- Dissecting the viscera

Examination begins with the most posterior structures and moved anteriorly layer by layer. Aorta, inferior vena cava, adrenal glands and posterior surface of the urinary system exposed and examined. Adrenal glands, kidneys, ureters and urinary bladder were examined. The vagina and uterus were opened in the anterior midline and examined. The liver, gallbladder and structures of the porta hepatis, portal vein, hepatic artery and common bile duct were identified and dissected as indicated [3].

The esophagus was opened in the posterior midline while intact with trachea. In this way a trachea-esophageal fistula can be identified and opened. Next the incision carried into the stomach. After major hilar structures of the lungs have been opened and inspected, attention was turned to the lungs. Lobation and condition of the visceral pleura were presumably ascertained. In case of bladder outlet obstruction, the entire urethra is examined for posterior urethral valves (or) other abnormalities (i.e., anterior urethral valves, mega urethra). Placenta was available in only few cases [3].

4-Histopathological examination

The organs after evisceration and external examination were fixed in 10% formalin. Blocks of tissues for microscopic examination were taken, one block from each lobe of both lungs. One block each from thymus, heart, stomach, liver, spleen, pancreas, small intestine, large intestine, kidneys, adrenals, and any doubtful lesions were taken. Sections were studied in the routine way with Haemato-xylin and Eosin (H&E) stains. Special stains were done whenever necessary and studied. Autopsy findings were compared with ultrasound findings whenever available.

Results

In present study out of 217 patients 213 (98%) were fetal death and 4 (2%) cases of neonatal death were included in present study. Among 217 cases 51 found to anomalous. Relation between maternal age and neonatal death mean age of mother was 29 years. 99 (45.6%) fetal death seen in maternal age group was 20-24 years. While in neonatal death maternal age most commonly involved was 25-29 years.

External anomalies most commonly seen in present study was Neural and spinal malformations that included 77% of external anomalies. While Lymphatic system & Circulatory system involvement was only 5.5% in present study.

In Internal congenital anomalies diaphragmatic hernia (40%) was most common anomaly seen followed by atelectasis of lung i.e. 33% in present study. Cardiac and genitourinary anomalies involvement was 13% respectively.

Relationship between anomalous fetus and weight of fetus reveals that 47 anomalous fetus had weight of 1000 gm, 800 gm & 750 gm respectively while 4 fetus had normal weight range 2.5 to 3.5 kg. And 30-34 year of maternal age involved maximum number of anomalous fetus which was 47% seen in present study.

Anomalous pattern in 22 male fetus involved Neural and spinal Malformation (8 cases) > Pulmonary malformation (6 cases) > cardiac malformations (3 cases) > genitourinary & Renal malformation (1 case) and in miscellaneous 4 cases

2 cases diagnosed as Edwards syndrome. while anomalous pattern in female fetus included no of cases were 28, female fetus it s bit higher incidence as compare to male fetus anomalies ratio of anomalies in study was 1:1.3, Neural and spinal Malformation (8 cases) > Pulmonary malformation (7 cases) > Genitourinary & Renal malformation (6 cases) > cardiac malformations (1 case). In miscellaneous category total number of cases were 6 cases among them 2 cases diagnosed as Klipilfeil Syndrome & 2 cases diagnosed as Achondrodysplasia in present study. Thanatropic dysplasia seen in 1 case (sex was not determined). As we mentioned consensual marriage incidence in our study is 83%, 180 cases had history of consensual marriage a great significance in formation of anomalous fetus pattern and preventable cause by spreading awareness among population subgroups. There is no toxicological study done in present study due to lack of any relevant significance because cause of death known in all cases as malformation.

Discussion

Fetal autopsy significantly contributes to the diagnosis of intrauterine fetal death and congenital anomalies are a major cause of perinatal death. Congenital malformations in fetal and neonatal deaths vary in different studies. The study of malformations greatly helpful in genetic counseling

and prenatal diagnosis in successive pregnancies1.

In the present study 217 fetal and neonatal autopsies were carried out among 213 fetal and 04 neonatal deaths that occurred in PIMS, during the period from Jan 2018 to Oct 2018. Prevalence of Congenital malformations account for 23.5% of fetal and neonatal deaths. This incidence matches with the study by Rabah M. Shawky, Nermine S. Elsayed

Maternal Factors

In present study, the incidence of congenital malformations were higher in mother's age group of 25 to 39 years. In 25 to 29 years out of 217 fetal and neonatal deaths 20 (9.2%) cases got anomalies. In 30 to 34 years of maternal age group, 24 (11.05%) cases got anomalies. In 35-39 years of maternal age group, 07 (3.2%) cases got anomalies many authors have shown higher incidence of malformations in the babies born to maternal age between 20 to 35 years. The observations in the present study is that 90% of the cases belong to multi gravid and 10% cases belong to primi gravida. In our study the incidence of congenital anomalies were increased with the increase in maternal age

Fetal Factors

In present study, the incidence of congenital malformations were higher among the low birth weight infants (<1500 gm) in comparison to the normal weight accounting for 04 cases. The association of low birth weight and malformations has been well documented. Many studies have documented male predominance amongst congenital malformed babies. However, in the present study we observe 22 male babies and 28 female babies with congenital malformation. In a five year study on major congenital anomalies in Turkey by Tomtair et al., 14 there were 183 cases (2.9/1000) of single (or) multiple congenital Anomalies among 63,159 live births. The most common anomalies were related to the nervous system (31.1%), cleft palate and lip (18.6%), musculoskeletal system disorder (14.2%) and chromosomal anomalies (13.1%). Both genders were found to have greater anomalies related to the nervous system (34.9% of girls and 28.3% of boys) while amongst.

In present study CNS malformation is the most common. (17cases 8%) in 217 cases. Among them most common follows the order Meningocele > Anencephaly > Hydrocephalus. Second most common malformation is pulmonary malformation (13 cases 6%) in 217 cases ,most common is Diaphragmatic Hernia than Atelectasis of Lung. Urogenital malformation (7 cases 3.2%) in 217 cases – with female predominance.

Benefits of Autopsy

The direct benefits of autopsy to parents are not limited to refining the risk of recurrence. Even after autopsy, sometimes a definitive final diagnosis cannot be made and information given to parents may cover a range of possible diagnoses. In such cases the storage of fetal samples for possible future genetic analysis provides the hope of an accurate diagnosis (which may have ramifications for the wider family) at a much later date. In most cases in which the scan findings are confirmed parents can gain comfort that their baby had the prenatally suspected condition. The finding of additional malformations, as well as in some cases changing the diagnosis, may be helpful in targeting tests in a subsequent pregnancy. A wider importance of autopsy is in its value for quality control for prenatal diagnosis, teaching, and research [5].

The decline in autopsy rate and issues surrounding the retention of tissues and organs for diagnostic studies, teaching, and research has been the subject of much debate since the adverse publicity concerning autopsies and organ retention Parents should be provided with full information and not be coerced into accepting an autopsy examination. It is important that those advising them at such a sensitive time do not take what may be the superficially kinder route of avoiding detailed discussion about the autopsy. Parents need full information about the potential benefits of the examination, including details both about the procedures involved and about the benefits in providing information about risks of recurrence if they are to make a truly informed decision. This discussion should be with an appropriately trained professional [5].

Our study provides important information for parents. If a termination has been carried out because of anomalies detected by ultrasound scan, by declining an autopsy, parents will remain ignorant of information of recurrence risk.

Conclusion

The study of dead is to save the livings. Congenital malformations have become important cause of fetal and neonatal mortality in developed countries and would very soon be increasingly

important determinants of fetal and neonatal mortality in developing countries like India and of various states- like Rajasthan, Karnataka & Andhra Pradesh where consensual marriage is common which is known cause of congenital malformation This study was undertaken with the purpose of finding out cause of death during the perinatal & neonatal period at PIMS Udaipur, to see pattern and prevalence of congenital anomalies and implication of legal aspects of fetal autopsy.

Confliction of interest: No

Cyto-Histopathological Correlation of Breast Lump as a Part of Internal Quality Control

Shikha Goyal, Manish Mewani*

Assistant Professor, Department of Pathology, Ananta institute of Medical Sciences and Research Centre, Rajsamand, Rajasthan

ABSTRACT

Background: *Breast malignancy is the most widely recognized tumor in females around the world. With the advent of fine needle aspiration cytology (FNAC), the approach to diagnosis and management of breast lesions has been revolutionized. Its accuracy in many situations can approach that of histopathology in providing an unequivocal diagnosis.*
Hence a review was undertaken with the following objectives.
1. To correlate cytological and histopathological diagnosis of breast lesions as a part of internal quality control.
2. To know the incidence of false positive and false negative cases.
3. To find out the sensitivity and specificity of FNAC of breast lesions.
Methods: *This study was conducted for a period of 2 year and 102 aspirations of breast lumps studied. Out of which 82 cases were followed- up by histopathological correlation.*
Results: *Cytological diagnosis in general was divided into four categories, benign (76.29%), malignant (18.29%), suspicious (2.44%), and unsatisfactory (00). Age of the patient was range from 16 - 62 years with mean age of 32 years. There were 76 female patients and 06 male patients. Fibroadenoma (54.87%) was most common benign neoplasm. The two cases which were categorized as "Epithelial Hyperplasia, Suspicious" by cytology turned out to be malignant lesions on histopathology. Sensitivity and specificity of FNAC in breast lesions were reported to be 88.24 % and 100% respectively, with 100% positive predictive value and 97.01% negative predictive value.*
Conclusion*: Considering the high specificity and sensitivity of aspiration cytology in the cases of breast lesion, it can be established as an internal quality control at tertiary centre to minimize economical stress demanded for EQAS (External Quality Assessment Scheme).*

INTRODUCTION

A palpable breast lump is a common diagnostic problem both to the general practitioner and to the surgeon.[1] In addition to enormous reservoir of benign pathology, breast cancer is the most common form of cancer among women and the second most common cancer in the world, trailing only lung cancer.[2] Women have a lifetime breast cancer risk of approximately 1 in 8 (12%) and is one of the leading causes of cancer mortality among woman.[3]

Traditional management of breast lumps has been surgical biopsy. As the number of biopsies has increased, the cost of screening for breast cancer is also increased. The need for cost containment has led to interest in alternative methods to open biopsy that could provide definitive diagnosis of breast cancer. Fine needle aspiration represents such an alternative technique.

FNAC can reduce the number of open breast biopsies.[4] It has been shown that, clinical examination in conjunction with fine needle aspiration cytology and mammography, also known as "triple approach" can divide almost all breast

lesions preoperatively into benign and malignant categories. This technique was suggested by Kreuzer and Boquoi (1976)[5] and Hermansen et al (1987).[6]

The concept of quality control, which is deeply rooted in most other disciplines of laboratory medicine, is relatively young in the histopathology department. Unlike in other disciplines of laboratory medicine, assessment of analytical aspects in histopathology is not easy given the subjectivity of the reports. Error detection and avoidance in histopathology has been written about very often.[7-11]

The present study was undertaken with the aim of cyto-histopathological correlation to understand the lesion more clearly and if it can be used as one of the objective criteria for Internal Quality Control.

METHODS

The present study was carried out at Ananta institute of Medical science and research Centre, Rajasthan. FNAC was done on 107 patients with breast lesions, among which cyto-histopathological correlations were obtained in 82 cases. FNAC was done by standard procedure on palpable breast lumps. Palpable axillary lymph nodes, wherever indicated, were aspirated to exclude metastases. The slides were stained with Papanicolaou stains. Correlation with imaging studies, including mammography, was done.

The surgical specimens received were fixed in 10% formalin. The gross and cut section findings were noted. Several bits were taken from appropriate sites for processing and paraffin embedding. From each block, sections were cut at 4-5 microns thickness and stained by H&E.

The breast samples from FNAC were further sub-classified into definite breast disease entities. The final histopathological diagnosis of each case was then compared with the cytological diagnosis.

Results thus obtained were subjected to statistical analysis.

RESULTS

A total of 107 cases of FNAC were analyzed into the study. Out of 107 cases, 82 (76.63%) histopathology correlations was done in the department. The 6 (7.32 %) cases were male while 76 (92.68%) were female. Age of the patient was range from 16 - 62 years with mean age of 32 years.

Table 1: Age incidence of breast lesions (of 82 cases)

Age range	No. of cases	Percentage
0-10	00	0 %
11-20	22	26.83 %
21-30	31	37.80 %
31-40	18	21.95 %
40-50	07	8.54 %
>50	04	4.88 %
Total	82	100 %

Table 2: Sex incidence

Sex	Total no. of cases	Percentage
Female	76	92.68 %
Male	06	7.32 %

Cytological diagnosis of 82 aspirations was reviewed and lesions were classified into four diagnostic classes revealing 65 (79.26 %) benign lesions, 15 (18.29%) malignant, 02 (2.44%) suspicious and nil inadequate.

Tab 3: Cytological findings in breast FNA smears in general

Cytological diagnosis	No. of cases	Percentage
Benign	65	79.26 %
Malignant	15	18.29 %
Suspicious	02	2.44 %
Unsatisfactory	00	00 %
Total	82	100 %

Table 4: FNAC diagnosis of Breast Lump

Cytological diagnosis	No. of cases	Percentage
Fibroadenoma	45	54.87 %
Chronic Mastitis	04	4.87 %
Granulomatous Mastitis	02	2.44 %
Galactocele	02	2.44 %
Fibrocystic Disease	05	6.10 %
Gynecomastia	06	7.31 %
Phyllodes tumor	01	1.22 %
Epithelial Hyperplasia, Suspicious	02	2.44 %
Carcinoma Breast	15	18.29 %

In our study we have recorded 45 (54.87%) cases of Fibroadenoma. The 91 % of fibroadenoma cases were seen in the age group of 15-35 yrs. Histopathology available in all 45 cases of Fibroadenoma which shows 100% sensitivity and specificity for FNAC.

This study documented the fact that benign breast lesions were the most common lesions in young females, among which the Fibroadenoma was the commonest one. The malignant lesions were common in fourth and fifth decades of life. The two cases which were categorized as “Epithelial Hyperplasia, Suspicious” by cytology turned out to be malignant lesions on histopathology and they were diagnosed as Invasive ductal carcinoma. Rest of all cases showed good correlations between FNAC and histopathology.

Following cyto-histopathological correlation, sensitivity, specificity, positive predictive values were calculated in accordance with Park. There were two false negative cases and no false positive cases in this study. In the present study, the sensitivity in diagnosing malignant lesions was 88.24%, specificity was 100 %. PPV and NPV were 100 % and 97.01 % respectively.

DISCUSSION

FNAC of breast lumps is an accepted and established method for determining the natures of breast lumps with a high degree of accuracy.[12,13] Most of the patients with breast lumps are in a state of anxiety. So, in reducing anxiety and unnecessary surgical procedures as well as in minimization of delay in the diagnosis, FNAC proves very fruitful. FNA procedure is a safe method with only a few reported complications. It has been reported in the literature that the incidence of tumour transplantation along the needle track by FNA procedure is only about 0.0045%, and even much lower in superficially located tumours.[14]

In the present study, all the 15 cytologically diagnosed malignant cases were confirmed as malignant on subsequent histopathological examinations. So, in our study, a 100% cyto-histopathological correlation was observed for malignant lesions. Khemka et a,l[15] Ramesh S et al[16], Tiwari M[17] had also observed the same results in their studies.

Table 5: Cyto-Histopathological Correlation (n=82)

FNAC↓	Histopathological Diagnosis →						
	Inflammatory Lesion	Fibroadenoma	Fibrocystic disease	Phyllodes tumor	Galactocele	Gynecomastia	Breast carcinoma
Inflammatory Lesion	06						
Fibroadenoma		45					
Fibrocystic Disease			05				
Phyllodes tumor				01			
Galactocele					02		
Epithelial Hyperplasia, Suspicious							02
Gynecomastia						06	
Carcinoma Breast							15

Table 6: Calculation of statistical value

FNAC	Histopathology	
	Benign	Malignant
Positive for Malignancy	00	15 (TP)
Negative for Malignancy	65 (TN)	02 (FN)
Total	65	17

Table 7: Statistical indices of present study

Statistical indices	TP	TN	FP	FN	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
	15	65	00	02	88.24%	100%	100%	97.01%

Table 8: Comparison of sensitivity, specificity, positive predictive value and negative predictive value by various authors

Author	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
Khemka et al [15]	96	100	100	95.12
Ramesh S et al [16]	88.24	100	100	93.2
Tiwari [17]	83.3	100	-----	-----
Pandit et al [18]	83	100	100	91
Norton et al [19]	89	100	100	90
Bojia F et al [22]	94.3	78.6	68.8	96.5
Watson DP et al [23]	74	99.6	68.8	96.5
Clive et al [24]	92	100	100	85
Kline et al [25]	86	100	100	95
Wanebo et al [26]	99	100	100	99
Present Study	88.24	100	100	97.01

In the present study, 2 cases which were cytologically diagnosed as lesions "suspicious for malignancy" were confirmed as malignant lesions on doing histopathological studies. Other studies also noted an increase in rate of malignancy on histopathology in lesions which were previously diagnosed under the category of "suspicious lesions for malignancy". The sensitivity of our study is 88.24% similar results has been observed with other studies.[16-19]

A difference was noted in the incidences of benign and malignant breast lesions amongst various studies, which may be explained on the basis of variables like the duration of study period, number of cases studied, age group of patients, etc.

In developing countries like ours, economical restrictions, low budget for health care and screening program put the patients at a disadvantage because of the high cost of sophisticated diagnostic methods, thus we recommend that FNAC be used as a routine diagnostic method because of its low cost compared with the others and this policy maximizes the availability of health care to women with breast cancer.

CONCLUSION

FNAC is an initial diagnostic modality in breast lumps. It is fairly safe procedure and it gives reasonably accurate results, thereby helping the clinicians to plan the best line of treatment. The high specificity and a high negative predictive value for malignancy illustrates the high accuracy of FNAC in the diagnosis of malignancy in the breast. Hence the cyto-histopathological correlation can be used as one of the criteria for internal quality control.

Relationship of Platelets Count and Serological Marker of Dengue Infection: A Prospective Study

Sunanda Chauhan

Assistant Professor, Department of Pathology, Ananta Institute of Medical Sciences and Research Centre, Rajsamand

ABSTRACT

Background: *Dengue fever is a mosquito-borne virus disease of humans. In terms of numbers of individuals infected, it is by far the most devastating of all the recognized arthropod-transmitted virus diseases. It is estimated that more than 3 billion humans live in dengue endemic regions of the world, and currently, more than 50 million infections occur annually with at least 500,000 individuals requiring hospitalization.*

Methods: *This study was conducted in Department of Pathology, Ananta Institute of Medical Sciences and Research Centre, Rajsamand. A total of 160 serum positive samples from clinically suspected dengue patients attending outdoors, causality services and indoor patients were included in this study. Five milliliter of blood was collected from all suspected cases of dengue fever.*

Results: *In our study, 525 total samples were included in this study. 160 samples were positive out of 525 samples. In the present study, 53.7% were males and 46.3% were females. In this study showed relationship between Platelet count and other parameters. From which notice that, 110 patients had less than 1 lakh count.*

Conclusion*: Thrombocytopenia found in case of fever which is more constantly in dengue positive sooner than dengue negative cases. It correlates well when NS1 & IgM are found simultaneously.*

Key words: *febrile illness, Dengue virus, endemic, IgM, IgG, NS1*

INTRODUCTION

Dengue is an acute febrile illness which is endemic to the Indian subcontinent. It is one of the most significant mosquito-borne viral diseases transmitted to humans by the *Aedes aegypti* mosquitoes.[1,2]

It is caused by the Dengue virus (DENV) belonging to the family *Flaviviridae*. On the basis of the neutralization assay data, four serotypes (DENV-1, DENV-2, DENV-3, and DENV-4) have been distinguished. DENV infection is a major cause of sickness in tropical and subtropical countries.[3-6]

Each year almost 100 million people are infected. Out of these, 5,00,000 people suffer from dengue hemorrhagic fever (DHF) and dengue shock syndrome (DSS) with 30,000 fatalities, mostly of children.[7]

There are three basic methods for the diagnosis of dengue virus infection. These are viral isolation, detection of the viral genomic sequence by a nucleic acid amplification technology assay (Reverse transcription polymerase chain reaction (RT-PCR)), and detection of dengue virus-specific IgM antibodies by the IgM-capture enzyme-linked immunosorbent assay (MAC-ELISA) and/or the rapid dengue immunochromatographic test (ICT).

The laboratory methods should be rapid and sensitive to reduce the morbidity and mortality of the dengue.[8] The antibody (IgG/M) detection is the most commonly used method for diagnosis of dengue infection but it is not a rapid method because time needed for appearance of IgM antibody is approximately 4-6 days.[9] Dengue non-structural 1 antigen (NS1) is highly conserved glycoprotein produced in both membranes associated and secretory forms is a new biomarker which is used for early diagnosis of dengue infection.[10]

Besides the dengue specific parameters, platelet count is the only other accessory lab test that can support the diagnosis of DHF or DSS. The platelet counts can be rapidly, easily and roughly estimated by microscopy even in the remotest of the areas.[11]

With this background it was planned to study correlation of the platelet count and microbiological laboratory tests of detection of NS1 antigen and IgG/M antibody tests in dengue suspected patients attending hospital.

METHODS

This study was conducted in Department of Pathology, Ananta Institute of Medical Sciences and Research Centre, Rajsamand. A total of 160 serum samples from clinically suspected dengue patients attending outdoors, causality services and indoor patients were included in this study. Five milliliter of blood was collected from all suspected cases of dengue fever. Serum was separated from all blood samples and was further tested for NS1 Ag and the presence of IgM and IgG Dengue antibody by dengue day1 test (J. Mitra) according to manufacturer s instructions.

Platelet Count:-

EDTA blood samples were collected and the platelet count was done by automated analyzer and cross checked by microscopy in the Department of Pathology, AIMSRC.

Ethical Considerations:

This was a analysis of routine laboratory diagnostic work thus ethical approval was not necessary.

RESULTS

In our study, 1052 total samples were included in this study. 160 samples were positive and 892 samples were positive out of 1052 samples. In the present study, 53.7% were males and 46.3% were females. In this study showed relationship between Platelet count and other parameters. From which notice that, 110 patients had less than 1 lakh count.

Table 1. Positive sample found from total number of sample

Sample	No. of sample	Percentage
Positive	160	15.2%
Negative	892	84.7%
Total	1052	100%

Table 2:- Gender-wise distribution

Gender	No. of Patients	Percentage
Male	86	53.7%
Female	74	46.3%
Total	160	100%

Table 3:- Various dengue Parameters in diagnosis of dengue cases

Parameters	No. of Patients	Percentage
NS1	48	30%
IgM	80	50%
IgG	5	3.1%
NS1 & IgM	17	10.6%
NS1 & IgG	1	0.6%
IgG & IgM	9	5.6%
TOTAL	160	100%

Table 3:- Relationship of platelets count with other parameters

Parameters	No. of Patients	Platelets less than 1 lakh	Percentage
NS1	48	35	31.8%
IgM	80	48	43.6%
IgG	5	4	3.6%
NS1 & IgM	17	16	14.5%
NS1 & IgG	1	1	0.9%
IgG & IgM	9	6	5.4%
TOTAL	160	110 (68.75)	100%

DISCUSSION

The detection of dengue-specific antibodies IgG/M has been the main diagnostic modality of DI for a long. The dengue-specific antibodies appear from fifth day of fever in primary infection[5] and from third day in the most secondary infections.[9] Thus, both in primary and secondary DI, there is a window period when only antibodies can be tested. On the other hand, the NS1 antigen can be detected from first day of fever both in primary and secondary infections. NS1 antigen test has been reported to be highly specific viral marker and an extremely reliable parameter for the diagnosis of DI from first day of the fever.[10] Out of the 160 cases reported in the present study, 48 cases (30%) were positive only for NS1 antigen indicating if the NS1 antigen test had not been included in the study, the 30% cases of DI had been missed.[11,12] Almost the similar findings were reported by Datta and Shrivastava in their studies.[10,13] In the present study, NS1 alone or in combination with IgM/G was positive in 66 cases (41.25% cases). IgG has been reported to be a less reliable marker in the diagnosis of DI between the two dengue antibodies test.[5] It has been found that antibody IgG can be produced both in clinical and sub-clinical infections and may persist even for several years.[14] High levels of IgG in endemic areas can be attributed to the bites of infected mosquitoes.

On the contrary, dengue-specific IgM is a good indicator of recent DIs. Along with primary, it can also be detectable in secondary DI. In antibodies test, the diagnosis of DIs mainly depends on rising titers while in NS1 antigen test, there is no need of repeat testing as it is a highly specific marker of DI.[5] Out of the 160 cases reported in the present study, 110 (68.75%) were having thrombocytopenia. Out of 66 cases positive for NS1, thrombocytopenia was evident in 52 cases. Contrary to this, thrombocytopenia was present only in 117 (61.6%) cases out of 190 cases positive only with antibodies tests. The association of thrombocytopenia with NS1 showed higher SEP test = 5.01, Z=3.51 and *P* value <0.001 (highly significant).

On analysis of NS1 only group (73.68%) with NS1 plus IgM (94.12%) group, thrombocytopenia was found to be associated more with NS1 plus IgM group (SEP = 6.06, Z=3.37, *P*<0.001, highly significant).

It has been reported that platelet counts are decreased in some other conditions such as some viral infections other than DI, drug induced thrombocytopenia, collagen vascular diseases, idiopathic thrombocytopenia etc.[3]

In the present study, On statistical analysis (SEP = 4.55, Z=8.51, *P*<0.001), it was found that the association of thrombocytopenia and dengue parameter was significantly higher in comparison to thrombocytopenia and dengue negative cases.

CONCLUSION

In the diagnosis of dengue, presence of NS1 antigen increases the detection rate significantly. Thrombocytopenia found in case of fever which is more constantly in dengue positive sooner than dengue negative cases. It correlates well when NS1 & IgM are found simultaneously.

The Prospective Study on Acute Leukemia in Tertiary Care Teaching Hospital in Rajsamand

Sunanda Chauhan

Assistant Professor, Department of Pathology, Ananta Institute of Medical Sciences and Research Centre, Rajsamand

ABSTRACT

Background: *Acute leukemia are characterized by clonal expansion of immature myeloid or lymphoid precursors (blasts). The blasts cells are known to replace the normal hematopoietic tissues and to invade other organs of the body as well. Anemia, hemorrhage and infections occurring due to bone marrow failure are the top three complications of acute leukemia.*
Methods: *This study was carried out in the Department of Pathology, Ananta Institute of Medical Sciences and Research Centre, Rajsamand*
Results: *In The present study, 32 cases of different patterns of acute leukemia were reported. According to hematological parameters, 25 cases (78.1%), 2 cases (6.25%), 3 cases (28.1%) and 2 cases (6.25%) were reported as acute leukemia, AML, ALL and bi-lineage leukemia respectively.*
Conclusions: *The present study showed that AML is more prevalent than ALL. It is observed that ALL is more common in children. The incidence of AML is higher in adults in comparison to children and decreases towards older age.*

Keywords: *acute leukemia's, heterogeneous, hematological ,ALL, ALM*

INTRODUCTION

It is a known fact that acute leukemias are heterogeneous group of hematological malignancies. Acute leukemias are characterized by clonal expansion of immature myeloid or lymphoid precursors (blasts). The blasts cells are known to replace the normal hematopoietic tissues and to invade other organs of the body as well. Anemia, hemorrhage and infections occurring due to bone marrow failure are the top three complications of acute leukemia[1-3] and may even be fatal. Acute leukemias are among the most common childhood cancers. The percentage of blasts should be more than 20% in the marrow or peripheral blood for diagnosing as per WHO classification.[4]

Acute leukemias are classified morphologically, in two types acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL). AML is the most common type of leukemias in adults while ALL, accounting for 80% of the total cases, is the most common type in children.[5,6] ALL is further subclassified in three subtypes L1-L3 while AML in eight subtypes M0-M7.[7] some cytoplasmic and surface proteins known as cluster differentiation (CD) antigens are expressed by every blood cell. A unique set of CD antigens is expressed at every level of differentiation. The identification and quantification of cellular antigens through fluorochrome labeled monoclonal 7 antibodies are known as immunophenotyping.[8]

METHODS

Study population:- A total of 32 cases of acute leukemia's were reported in the Haematology section.

Study Area:- This study was carried out in the Department of Pathology, Ananta Institute of Medical Sciences and Research Centre, Rajsamand.

Data Collection:- The complete haemograms were determined according to standard laboratory procedures. Slides were prepared with peripheral blood and in selected cases bone marrow aspirates which were stained by 'Leishman stain' and 'Giemsa stain' to find out the blast cells morphology in peripheral blood and bone marrow. Diagnosis of acute leukemia was made in cases where blast percentage was ≥20% (WHO guideline) and then Flow cytometric immunophenotyping was performed to distinguish between AML & ALL.

Data analysis:-Data were analyzed by using Microsoft excel.

RESULTS

In The present study, 32 cases of different patterns of acute leukemia were reported. According to hematological parameters, 25 cases (78.1%), 2 cases (6.25%), 3 cases (28.1%) and 2 cases (6.25%) were reported as acute leukemia, AML, ALL and bi-lineage leukemia respectively. The lowest blast percentage was 18.7% and highest was 31.25%. The hematological diagnosis (by means of complete blood count (CBC) / peripheral blood smear (PBS) / bone marrow aspirates (BMA)) and the number of cases that fall in different ranges of haemoglobin (Hb) level, total leucocyte count (TLC), platelet count (Plt.) and blast percentage are detailed in chart 3-7.

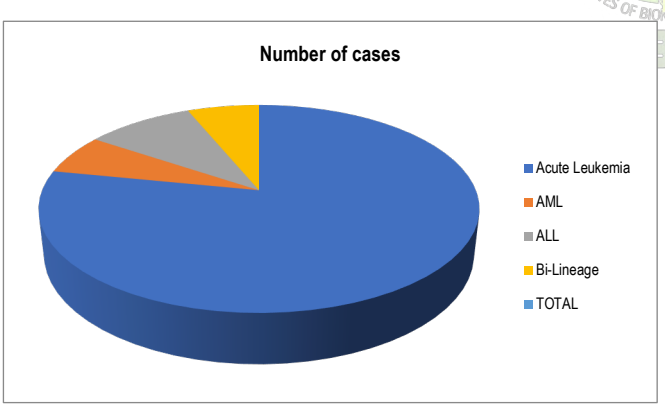

Chart 1: Distribution of hematological diagnosis

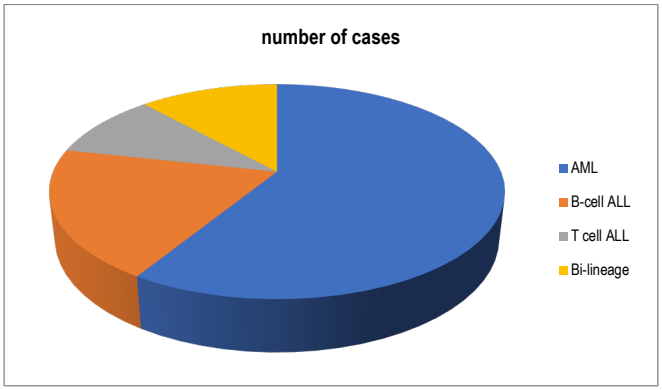

Chart 2: Distribution of Immunophenotypical diagnosis

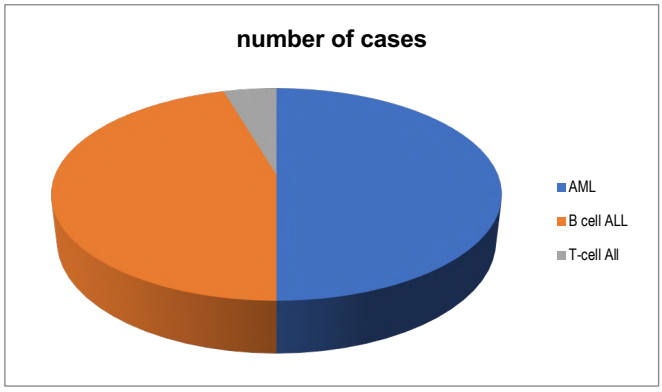

Chart 3: Distribution of Immunophenotypical diagnosis

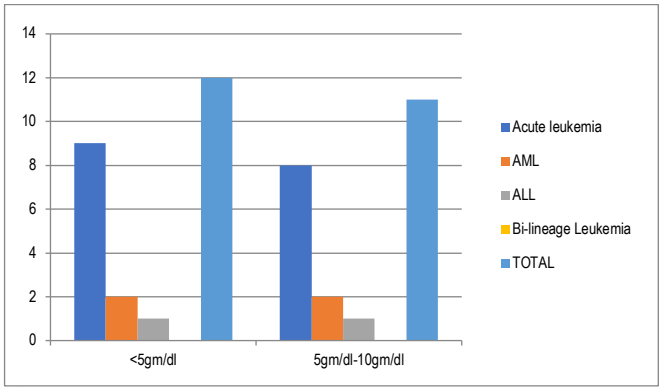

Chart 4: Hemoglobin findings of all cases presenting as acute form of leukemia

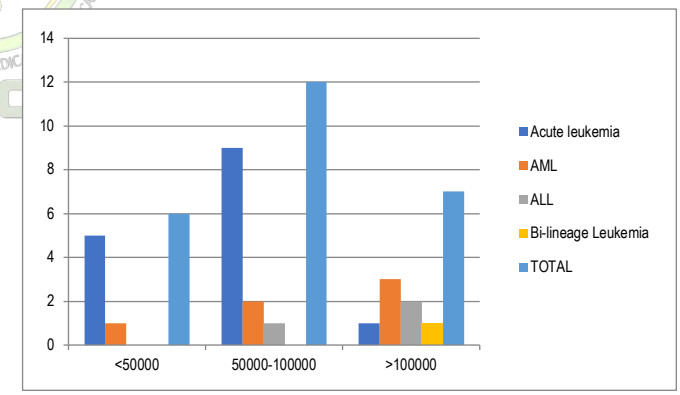

Chart 5: Total leucocyte count findings of all cases presenting as acute form of leukemia

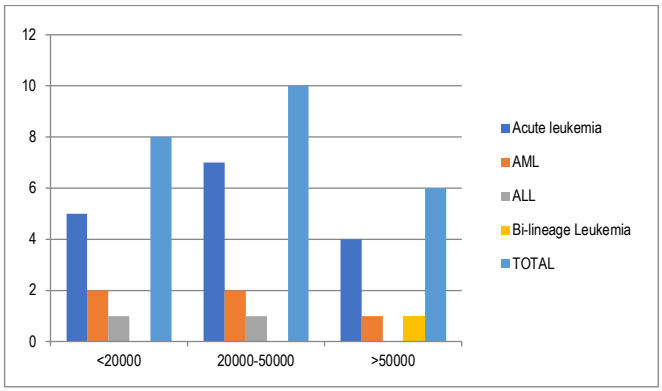

Chart 6: Platelets count findings of all cases presenting as acute form of leukemia

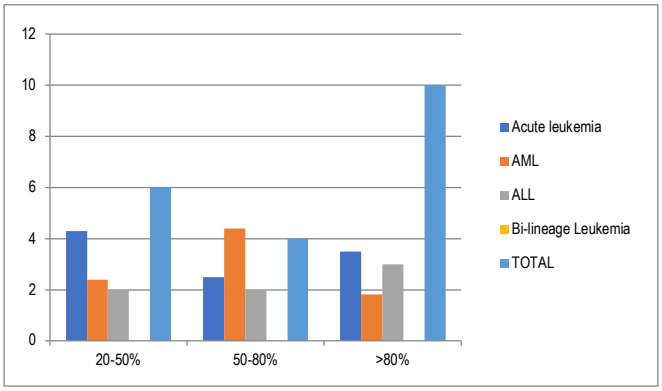

Chart 7: Platelets count findings of all cases presenting as acute form of leukemia

DISCUSSION

In the present study, anaemia was diagnosed in all cases and 37.5% of the total cases presented with severe anaemia with less than 5.0 g/dl of haemoglobin concentration. TLC was found to be more than 50,000/ cu.mm in 25% of patients, while such high TLC was present in only forty to fifty percent of cases in western studies.[9] 18.75% of the patients presented with less than 50,000/cu.mm platelet counts while 25% of patients had severe thrombocytopenia with platelet count less than 20,000/cu.mm. The results of the present study were almost similar to the local studies but on comparison with western studies, the results are more manifested. These marked results can be attributed to the late presentation as the degree of anaemia; leucocytosis and thrombocytopenia are directly proportional to severity of bone-marrow failure.[10] Immunophenotypic observations of AML (HLA-DR, CD13, CD33, MPO) in the presented study were supported by other studies.[11-12] On the other hand, B-cell and T- cell ALL were diagnosed in immunophenotypically cases. These findings were supported by observations of Shanta V et al. and Magrath I et al.[13-14] The results of the present study of the aberrant expression of lymphoid antigens (CD22, CD79a) in AML were also similar to the findings of the Ghosh S et al studies. Considering the different types of acute leukemia it was observed that AML was more common than ALL . These results are closely resembled to results reported from Kenya in Africa.[15]

CONCLUSION

The present study showed that AML is more prevalent than ALL. It is observed that ALL is more common in children. The incidence of AML is higher in adults in comparison to children and decreases towards older age.

In morphologically challenging cases, it is also concluded that immunophenotyping is an important diagnostic tool to differentiate between AML and ALL. It is possible to subtype as well as to establish the lineage of the leukemia from immunophenotyping. It is also essential to monitor the progress of patients after chemotherapy in detection of minimal residual disease.

AbStrACt

background: There are instances when either we do not perform pre-operative biopsy due to the fear of spread of malignancy, or needle aspiration cytology is inconclusive. During surgical exploration for a benign pathology if surgeons find suspicious lesions, per-operative cytological diagnosis becomes important to rule out malignancy. The frozen section facility is available only at few large volume centres. So there is always a need for an easy and cheap alternative to frozen section that can help surgeons at low volume centres as well.

Aim: Aim of the study was to assess the reliability of imprint cytology in per-operative (immediate) diagnosis of malignancy.

material and methods: The present study was a prospective analysis of 69 specimens from suspected or diagnosed cancer patients that were sent for per-operative (or urgent) imprint cytology (IC) from July 2012 to Feb. 2014, at surgical oncology unit of our institute. All the specimens were then subjected to paraffin section (PS) and final reports were compared.

results: Out of 69 specimens 61 were found to be malignant, and five were found to be benign by both IC and PS. In all such situations IC helped us a lot in decision making regarding change in treatment plan further. The sensitivity and specificity of imprint cytology were 96.8 % and 83.3% respectively. The positive predictive value (PPV) of IC was 98.3 %.

Conclusions: The imprint cytology is a cheap and reliable method for per-operative diagnosis of malignancy. It can be used for per-operative confirmation of parathyroid glands before auto-implantation.

Key Words: Frozen section, Imprint cytology, Per-operative cytology, Touch cytology

INTRODUCTION

For past many years it has become a trend to have definitive diagnosis before surgery, as it helps in surgical planning, planning of neo-adjuvant therapy and in patient counselling. This practice has decreased the numbers of surgical explorations. Surgeons feel difficulty in planning out the extent of resection of lesion whenever initial tissue diagnosis is not available. Still there are instances when we do not perform pre-operative biopsy or cytology due to the fear of capsular rupture, needle tract seedling or spread of malignancy. Sometimes fine needle aspiration cytology (FNAC) or needle biopsy is inconclusive and we have to take surgical (excision) biopsy, and then plan the definitive procedure after biopsy report, thus making it a 2 stage procedure. Many times during surgical exploration for a benign pathology if surgeons find suspicious lesions, per-operative cytological diagnosis becomes important to rule out malignancy, as this may change the intra-operative surgical plan further. Since a long time frozen section (FS) and imprint cytology (IC) are considered as two methods of per-operative cytological diagnosis. After popularity of frozen section in practice, pathologists have given up interest towards imprint cytology. The frozen section facility is available only at few centres in India as compared to large number of hospitals and patients. So there is always a need for an easy and cheap alternative to frozen section that can help surgeons at low volume centres as well. The aim of this study was to assess the reliability of imprint cytology in per-operative (immediate) diagnosis of malignancy.

MATERIAL AND METHODS

The present study was a prospective analysis of 69 specimens from suspected or diagnosed cancer patients that were sent for per-operative (or urgent) imprint cytology

from July 2012 to Feb. 2014, at surgical oncology unit of our institute. In all these situations it was important to confirm (or to rule out) malignancy, as this would make a major difference in treatment plan or extent of resection or in initiating a specific treatment. At our hospital we did not have facility for frozen section. Many times we felt difficulty in decision making where per-operative cytological diagnosis was needed. So we started doing imprint cytology as an alternative to frozen section based on previous literature, along with systematic recording of data.

Slides were either made in operation theatre or fresh adequate tissue samples were taken and wrapped in saline soaked cotton gauss pieces and, sent to pathology laboratory for urgent imprint cytology. The imprint cytology slides were then prepared in pathology lab by standard technique, fixed and stained. The reporting was done by a senior pathologist who was expert in cytological diagnosis of malignancy. All the specimens were then subjected to paraffin section (PS) and final reports were compared.

RESULTS

The results are shown in table 1.

From various surgical explorations (or excision biopsies) suspicious 12 metastatic nodules, six breast lumps, two encapsulated ovarian masses and 14 lymph nodes (including celiac, pelvic or para-aortic lymph nodes) were examined and all found to be positive by IC and PS as well. In all such situations IC helped us a lot in per-operative decision making.

The sensitivity and specificity of imprint cytology were 96.8 % and 83.3% respectively. The positive predictive value (PPV) of IC was 98.3 %. The average time taken in reporting was 23 minutes.

The only false positive result of IC was a specimen of lower uterine fibroid protruding out of cervix with surface erosions. It was giving appearance of defined cervical cancerous mass clinically (including imaging), but showing only dysplasia in cervical biopsy. We did radical hysterectomy and send specimen for imprint cytology to rule out malignancy in cervical mass before pelvic lymph node dissection (PLND). The IC reported it as malignant and we did bilateral PLND. Later on in final PS report it was found to be a uterine fibroid with surface dysplasia, all nodes negative.

Now let me discuss with you the two false negative cases. There was a confirmed case of carcinoma cervix, confined to cervix only in imaging, opened for radical hysterectomy. On exploration there was a significantly large, hard, round right pelvic lymph node (LN), which was sent for imprint cytology. The IC reported it as granulomatous disease and we proceeded to radical hysterectomy. The LN was finally found to harbour metastatic cancer.

The second false negative report was from a per-operative biopsy of stomach suspicious of linitus plastica. Multiple endoscopic biopsies were negative for malignancy, but clinically patient was not improving and CT (computed tomography) scan was constantly showing a diffuse wall thickening. Surgery with per-operative cytology was planned. The tumour was inoperable on exploration, as it was infiltrating into porta and transverse mesocolon. A small full thickness stomach wall biopsy was taken and sent for IC, which was negative for malignancy. We took a large full thickness biopsy and based on clinical judgement closed the abdomen. Finally both showed carcinoma stomach.

In a known case of laryngeal malignancy, 'wide field laryngectomy' surgery was planned. During surgery all four parathyroid glands were isolated and cut. One fourth part of each was sent for confirmation by IC. In the report three were normal parathyroids (auto-implanted) and one was found to be metastatic LN (discarded), which were confirmed by final PS.

The sub typing of malignancy (although it was not a predecided criterion to report) was given in 22 IC reports, but it was changed finally in nine patients. This makes IC unreliable for diagnosis of specific subtype (PPV 59 % only).

DISCUSSION

Imprint cytology (IC) and frozen section (FS) are renowned techniques of per-operative cytology and the diagnostic accuracy of both is comparable. Liu et al have investigated the utility of intraoperative touch preparation with comparison of frozen section in 122 cases. The rate of correct diagnosis for touch preparation was 88.5% as compared to 86.1% for frozen section. The rate of incorrect diagnosis for touch preparation was 4.1% as compared to 2.5% for frozen.[1]

Scucchi et al compared 2,250 intraoperative cytology with frozen section with the final diagnosis achieved on paraffin sections. The diagnostic accuracy of each technique alone was 94.9%. For frozen section the sensitivity was 89.9% and specificity 97.9% as compared to the touch cytology, which had a sensitivity of 94.9%, and specificity of 96.8%.[2]

Guarda et al carried out a comparative study of the two techniques and found the accuracy of cytology and frozen section 98.4% and 99.2% respectively.[3]

The greatest advantage of IC examination is of not having artifacts, resulting in superb nuclear and cytological details.[1] IC provides better and crisp cellular morphological details and even some tissue architecture.[4] Very small fragments of tissue provide sufficient cells for IC, but difficult to process and report on FS. The diagnosis of very small lesions is therefore facilitated and tissue is saved for permanent section.[5] Certain tissues that cannot be studied by frozen section i.e. bone, necrotic tissue and fat etc. give accurate results on touch preparations.[1] IC was found to be more valuable in the field of neuro-pathology, lymph node and most of the epithelial tumours.[3] Parathyroid glands are correctly identified by IC, slightly more sensitive than FS.[5]

Used intraoperatively, the imprint method can provide valuable information when frozen-section interpretation is equivocal. IC is particularly valuable in the diagnosis of certain neoplastic lesions which can simulate inflammatory lesions on FS eg. Well differentiated Pancreatic cancer, metastatic signet ring cell carcinoma in LN (can be mistaken for reactive sinus histiocytosis on FS). Certain benign inflammatory lesions can simulate malignancy on FS e.g. Organizing pneumonia (anaplastic carcinoma), intense sinus histiocytosis (can simulate metastatic carcinoma) that can be diagnosed with IC.[5]

Well-differentiated tumours and tumours with a dense fibrous stroma cannot be diagnosed by imprint cytology method.[5]

On the other hand Frozen Sections provided more tissue architectural details. It is well recognized, however, that the freezing and sectioning techniques of frozen section results in unavoidable distortions and artifacts, rendering diagnosis difficult in many instances.[1]

The diagnostic accuracy in distinguishing benign from malignant lesions by combined procedures was 100%. There were no false positive or false negative cases.[4] To increase diagnostic accuracy many people recommend the combined use of imprints and frozen sections.[5]

For diagnosing specific subtypes of malignancy, the diagnostic accuracy of each method alone was 96.6% with a sensitivity of 86% and specificity of 100% and the combined sensitivity 90%. The benefit of frozen section is that the tissue architecture closely approximates permanent histology sections.[4]

By virtue of our experience from this study, we would like to emphasize upon these few points:-

1. Imprint cytology is a reliable method to rule out malignancy in a short time. It may help surgeons to make changes in the previously made treatment plan. The confirmation of malignancy can help an oncologist to start therapy earlier without waiting for the results of final biopsy.
2. This method can be used to find out adequacy of biopsy specimen. Many times we are not sure while taking core biopsies (may be sonography or CT guided) that correct specimen is retrieved or not. Immediate imprint cytology from biopsy specimen will tell us that the tissue contains viable tumour, necrosed tissue or normal tissue. If the biopsy is not representative of disease we can take more samples immediately, hence to save time, patients' comfort and cost.
3. The imprint cytology can differentiate between a normal parathyroid gland and a lymph node with or without metastasis. This may help head and neck surgeons in per-operative confirmation of normal parathyroid glands before using them for auto-implantation. Now days, it is highly emphasised not to implant parathyroid glands without histological confirmation.
4. The imprint cytology is not a reliable investigation for sub-typing of cancer. It cannot differentiate between the grades of differentiation from well to poorly differentiated cancers. Its reliability on differentiating lung cancer into various subtypes like small cell, squamous cell or adenocarcinoma is not acceptable. Also it can't differentiate among various grades of dysplasia and early invasive cancer. This limitation should always be kept in mind.
5. Frozen section needs a good cryostat and other specialized materials along with experienced pathologist and technician. The cost of the setup ranges from Rupees 4 lac to 20 lac. There are problems regarding maintaining low temperature in the range of minus 15 to 20 ^{0} centigrade (sometimes even lower) with the cheaper cryostats along with issues regarding wastage of precious sample and poor quality of slides with cheaper devices. To make frozen section cost effective a centre should have at least 5 specimens for frozen section per day. This is the basic reason why frozen section is not available in majority of the hospitals even in big cities.

CONCLUSION

Imprint cytology is a cheap and reliable method for per-operative diagnosis of malignancy, and can be used in place of frozen section, where such facility is not available. It can be used for per-operative confirmation of parathyroid glands before auto-implantation.

ACKNOWLEDGEMENT

Authors acknowledge the support of head of the departments of general surgery, pathology and anaesthesia. Authors also acknowledge the support of nursing staff

and technical staff who were involved in the process of sampling, preparation, transportation, staining and other works. Authors also acknowledge all the patients who gave consent and supported for this study. Authors acknowledge the immense help received from the scholars whose articles are cited and included in references of this manuscript. A histopathological analysis of colorectal cancer

Syed Javed Arshi and Pankaj Bansal

DOI: https://doi.org/10.33545/pathol.2020.v3.i1b.156

Abstract
Background: Carcinoma of the colon or rectum is a common and lethal disease. The present study was conducted to assess histopathology of colorectal cancer.
Materials & Methods: The present study was conducted on 112 rectum specimens. Tumor invasion depth, surgical margin status, lymph vascular/perineal invasion, presence/absence of metastatic lymph nodes, neoadjuvant therapy, and regression rates were assessed.
Results: Out of 112 specimens, 64 were of males and 48 of females. There was mild treatment response in 21, moderate in 15, high in 14 and complete regression in 10 cases. Tumor type was adenocarcinoma in 76, mucinous adenocarcinoma in 23, malign melanoma in 6, signet ring cell carcinoma in 4, and gastrointestinal stromal tumor in 2 and endometriosis in 1 case.
Conclusion: Authors found that histopathology revealed that maximum cases were of adenocarcinoma followed by mucinous adenocarcinoma.

Keywords: Adenocarcinoma, colorectal cancer, histopathology

Introduction
Worldwide, colorectal carcinomas are the third most common carcinomas in men and the second most common carcinomas in women. A study conducted in 2014 reported that there are approximately 10 000 new cases of colon cancer and nearly 40000 new cases of rectal carcinoma annually in the United States. Deaths due to colorectal cancers account for approximately 9% of all cancer-related deaths. With changes in oncological treatments over the years, care should be taken to accurately perform pathological and clinical staging of these cases [1].
Carcinoma of the colon or rectum (colorectal cancer [CRC]) is a common and lethal disease. Approximately 145,600 new cases are diagnosed each year in the United States, of which 101,420 are colon and the remainder are rectal cancer [2]. Annually, approximately 51,020 Americans die of CRC, accounting for approximately 8 percent of all cancer deaths. Global, country-specific data on incidence and mortality are available from the World Health Organization (WHO) [3].
Surgical resection is the primary treatment modality for early stage CRC (stage I through III) and the most powerful tool for assessing prognosis following potentially curative surgery is pathologic analysis of the resected specimen. Although the parameters that determine pathologic stage are the strongest predictors of postoperative outcome, other clinical, molecular, and histologic features may influence prognosis independent of stage. Among patients with stage IV disease, prognosis is more closely tied to the location and extent of distant metastatic disease [4]. The present study was conducted to assess histopathology of colorectal cancer.

Materials & Methods
The present study was conducted to in the department of General pathology. It comprised of 112 rectum specimens. The study protocol was approved from institutional ethical committee.
Demographic data, etiology, and physiological and surgical parameters were collected from medical records. Tumor invasion depth, surgical margin status, lymphovascular/perineural invasion, presence/absence of metastatic lymph nodes, neoadjuvant therapy, and regression rates were assessed. When performing lymph node dissection, adipose tissue specimens were kept in alcohol overnight and were dissolved and solidified into adipose tissue components.

Results thus obtained were subjected to statistical analysis. P value < 0.05 was considered significant.

Results

Table 1: Distribution of patients

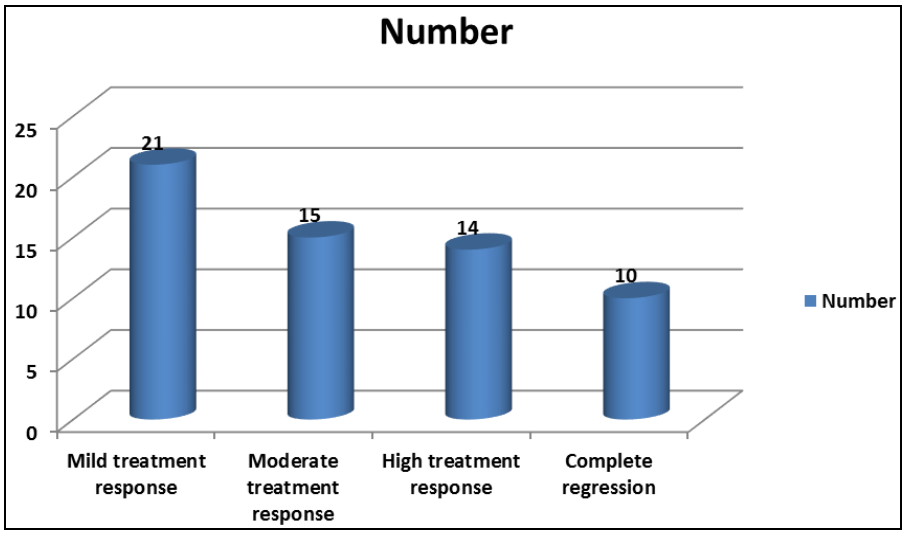
Total- 112		
Gender	**Males**	**Females**
Number	64	48

Table I shows that out of 112 specimens, 64 were of males and 48 of females.

Table 2: Regression responses of neoadjuvant treated patients

Response	Number	P value
Mild treatment response	21	0.12
Moderate treatment response	15	
High treatment response	14	
Complete regression	10	

Table II, graph I shows that there was mild treatment response in 21, moderate in 15, high in 14 and complete regression in 10 cases.

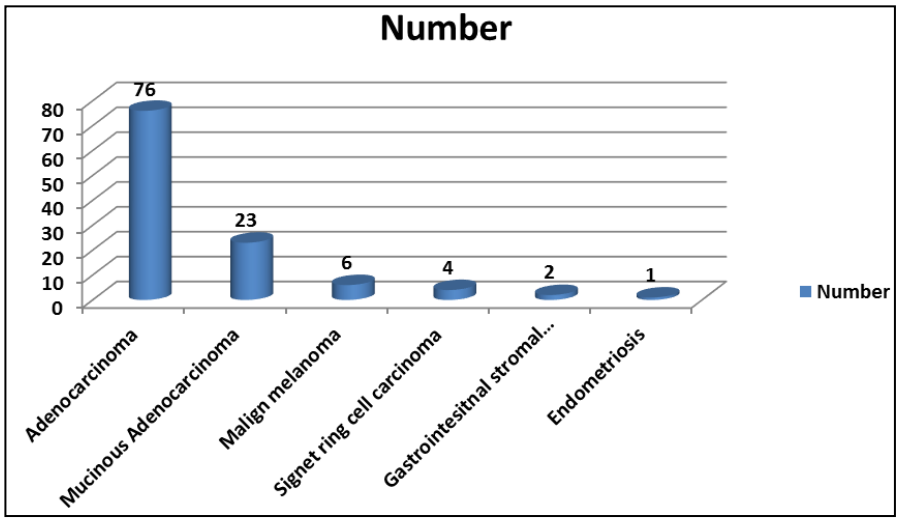


Graph 1: Regression responses of neoadjuvant treated patients

Table 3: Distribution of cases

Tumor type	Number	P value
Adenocarcinoma	76	0.01
Mucinous Adenocarcinoma	23	
Malign melanoma	6	
Signet ring cell carcinoma	4	
Gastrointesitnal stromal tumor	2	
Endometriosis	1	

Table III, graph II shows that tumor type was adenocarcinoma in 76, mucinous adenocarcinoma in 23, malign melanoma in 6, signet ring cell carcinoma in 4, gastrointestinal stromal tumor in 2 and endometriosis in 1 case.



Graph 2: Distribution of cases

Discussion

Colorectal cancer (CRC) is one of the most common malignancies and usually ranks high in incidence and mortality among all malignancies in the Western world.[5] Carcinoma of the rectum and sigmoid is one of the most sites of gastrointestinal tract malignancy and accounts for 20% of all gastrointestinal malignancies. The age-adjusted incidence rates of CRCs in all the Indian cancer registries are very close to the lowest rates in the world [6].

Pathological examination of rectum specimens requires special attention for correctly evaluating many prognostically important factors. Careful pathological examination is extremely important with respect to tumor invasion depth, surgical margin status, presence of lymphatic/vascular/perineural invasion, presence/absence of metastatic lymph nodes, presence of neoadjuvant therapy, and regression rates [7]. The present study was conducted to assess histopathology of colorectal cancer.

In present study, out of 112 specimens, 64 were of males and 48 of females. There was mild treatment response in 21, moderate in 15, high in 14 and complete regression in 10 cases. A *et al*. [8] found that of the 173 specimens, 15 (8.7%) were APR and 158 (91.3%) were LAR specimens. Ninety-four patients (54.3%) were males and 79 patients (45.7%) were females. The mean age of the patients was 63.5 years (range 26–90 years). In the histopathological examination, malignant neoplasm was detected in 172 of the cases (99.4%) and benign endometriosis was detected in 1 of the cases (0.6%). There were 151 (87.2%), 8 (4.6%), 5 (2.9%), 1 (0.6%), 1 (0.6%), 1 (0.6%), 1 (0.6%), 1 (0.6%), and 4 (2.3%) patients with adenocarcinoma, mucinous adeno-carcinoma, intramucosal adenocarcinoma in the setting of a high-grade tubulovillous adenoma, synchronous colon/prostate adenocarcinoma, malignant melanoma, signet ring cell carcinoma, gastrointestinal stromal tumor, endometriosis, and adenocarcinoma diagnosed by the examination of colonoscopic biopsy specimens that showed complete regression with neoadjuvant therapy, respectively.

In present study tumor type was adenocarcinoma in 76, mucinous adenocarcinoma in 23, malign melanoma in 6, signet ring cell carcinoma in 4, gastrointesitnal stromal tumor in 2 and endometriosis in 1 case. Singla *et al*. [9] found that rectum was the most common site of involvement followed by the recto-sigmoid involvement. Metastasis was observed in 5 cases out of the 31 malignant cases. Five of the 7 cases were correctly staged as T1 & T2 lesions on CT having a sensitivity of 83.3%, specificity of 92%, and positive predictive value of 71.4% and a negative predictive value of 95.8% in the diagnosis of T1 and T2 lesions. 15 of the 16 cases were correctly staged as T3 lesions. CT had a sensitivity of 88.2%, specificity of 93.8%, and positive predictive value of 93.8% and a negative predictive value of 86.7% in the diagnosis of T3 lesions. All the 8 cases were correctly staged as T4 lesions. CT had a sensitivity of 100%, specificity of 100%, and positive predictive value of 100% and a negative predictive value of 100% in the diagnosis of T4 lesions.

A study done by Pereira *et al*. [10] described that pericolic fat stranding is commonly seen in inflammatory conditions of the colon. Adjacent organ infiltration was seen in 8 cases (25.8% of total cases); however, the rest of the 23 cases did not show any involvement of viscera which means that the rate of detection of infiltration was 100%.

Conclusion

Authors found that histopathology revealed that maximum cases were of adenocarcinoma followed by mucinous adenocarcinoma.

A histopathological analysis of appendectomy specimens

Pankaj Bansal[1], Syed Javed Arshi[2]

[1,2]Associate professor, Department of Pathology, Ananta Institute of Medical Sciences and Research Center, Rajasthan, India

ABSTRACT:

Background: Appendicitis is a common acute surgical emergency. The present study was conducted to assess histopathology of appendectomy specimens. **Materials & Methods:** The present study was conducted on 89 appendix specimens. Data such as age, gender etc. was recorded in performa. Histopathological assessment was performed. **Results:** Out of 89 specimens, 52 were of males and 47 of females. Specimens found to be of appendicitis in 14, unusual pathology in 28, carcinoid tumor in 30 and mucinous lesion in 17 cases. The difference was found to be significant (P< 0.05). Age group 0-10 years had 6, 11-20 years had 17, 21-30 years had 24, 31-40 years had 21, 41-50 years had 13 and >50 years had 7 specimens. The difference was significant (P< 0.05). **Conclusion:** Authors found maximum case in age group 21-30 years with male predominance. Maximum cases found to be of carcinoids tumor.

INTRODUCTION

Appendicitis is a common acute surgical emergency with over 40,000 cases in the UK every year and the estimated life time risk of appendicitis in the USA is 8.6% and 6.7% for males and females respectively. The diagnosis of appendicitis is largely clinical and appendectomy is the treatment of choice.[1] Delayed diagnosis of appendicitis could lead to complications like perforated appendix, peritonitis, sepsis, increased morbidity and mortality. Right iliac fossa pain can be a presenting complaint of different pathologies that may mimic appendicitis especially in the female population causing diagnostic difficulties and often leads to negative appendectomies.

Acute abdominal pain is one of the most common earliest indicators of any clinical issues. The earliest known case of an appendiceal tumor dates back to 1882. Appendiceal tumors constitute 0.2% to 0.5% of all primary neoplasms seen in the gastrointestinal tract. This type of tumor is rare compared to other tumors that affect the gastrointestinal tract.[2]

Obstruction of lumen is the dominant factor in acute appendicitis and although faecoliths and lymphoid hyperplasia are the usual cause of obstruction, some unusual factors could be involved.[3] Unusual causes of obstructions are enterobiasis, ascariasis, tuberculosis, carcinoid tumor ,primary or secondary adenocarcinoma, lymphoma, dysplastic changes, mucocele, gastro-intestinal stromal tumor, eosinophilic granuloma etc. Even though, there are many case reports in English written medical literature, reports with meticulous analysis of all cases with appendicitis are small in number.[4] The present study was conducted to assess histopathology of appendectomy specimens.

MATERIALS & METHODS

The present study was conducted to in the department of General pathology. It comprised of 89 appendix

specimens. The study protocol was approved from institutional ethical committee.
Data such as age, gender etc. was recorded in performa. Histopathological assessment was performed. Results thus obtained were subjected to statistical analysis. P value < 0.05 was considered significant.

RESULTS

Table I Distribution of specimens

Total- 89		
Gender	**Males**	**Females**
Number	52	47

Table I shows that out of 89 specimens, 52 were of males and 47 of females.

Table II Histopathological findings in appendectomy specimens

Specimens	Number	P value
Appendicitis	14	0.05
Unusual pathology	28	
Carcinoid tumor	30	
Mucinous lesion	17	

Table II, graph I shows that specimens found to be of appendicitis in 14, unusual pathology in 28, carcinoid tumor in 30 and mucinous lesion in 17 cases. The difference was found to be significant (P< 0.05).

Graph I Histopathological findings in appendectomy specimens

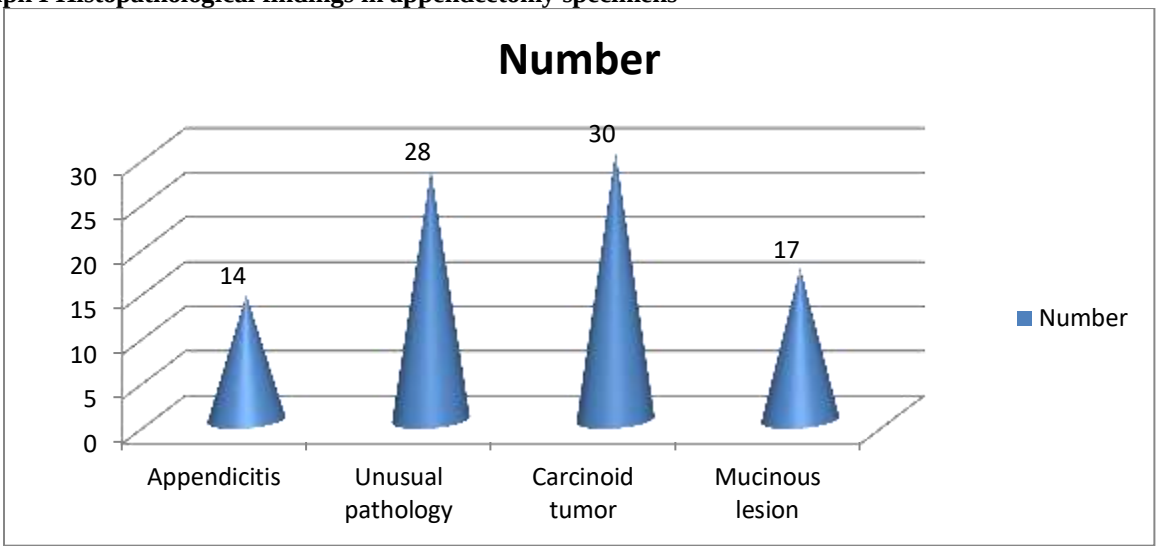

Table III Distribution of cases according to age group

Age group (Years)	Number	P value
0-10	6	0.04
11-20	17	
21-30	24	
31-40	21	
41-50	13	
>50	7	

Table III shows that age group 0-10 years had 6, 11-20 years had 17, 21-30 years had 24, 31-40 years had 21, 41-50 years had 13 and >50 years had 7 specimens. The difference was significant (P< 0.05).

DISCUSSION

There is variation in the practice of routine histopathological examination of appendectomy specimens. Arguments against the practice include the rarity of incidental pathologies that may impact on treatment and also the financial implications of routine histopathological assessments.[5]Acute appendicitis is the most common surgical emergency for a number of decades and the appendectomy is the most frequently performed abdominal operation. Obstruction of the lumen seems to be the essential for developing an appendiceal infection. Although faecoliths and lymphoid hyperplasia are the usual causes of the obstruction, some unusual factors could also be involved.[6] The present study was conducted to assess histopathology of appendectomy specimens.

In present study, out of 89 specimens, 52 were of males and 47 of females. Specimens found to be of appendicitis in 14, unusual pathology in 28, carcinoid tumor in 30 and mucinous lesion in 17 cases. Memon et al[7] found that a total of 238 appendectomies were performed during the study period. The mean age of the patients was 32 years (range, 7-81 years). Adult patients (>16 years) represented 79.4% of the study population. The female sex accounted for 46.6% of all the patients. Of the 238 resected appendix, 211 (88.7%) had histopathology findings consistent with appendicitis. Approximately 1.7% of the 238 specimens were abnormal pathologies other than inflammation of the appendix. The negative appendectomy (normal appendix on histology) rate was 11.3%. The female sex accounted for 59.1% of the negative appendectomies. Adults (>16 years) represented 77.8% of the negative appendectomies.

We found that age group 0-10 years had 6, 11-20 years had 17, 21-30 years had 24, 31-40 years had 21, 41-50 years had 13 and >50 years had 7 specimens. Emre et al[8] found that out of 790 appendectomy specimens, acute appendicitis accounted for 302 (38.2%) with peak occurrence in the age group 11-20 years (38.9%) and 21-30 years (27.7%) with male predominance (2.34:1). Unusual findings were noted in 44 (5.6%) cases by histopathology. Most common findings included obliterative appendicitis (77.3%), followed by eosinophilic appendicitis (6.8%) and granulomatous appendicitis (4.5%).Other unusual findings include diverticulum, mucocele, carcinoid and signet ring adenocarcinoma of the appendix.

Shrestha[9] reported the findings of a retrospective analysis of 261,134 patients who underwent non-incidental appendectomies with a NAR of 15.3%. When compared with patients with appendicitis, negative appendectomy was associated with a significantly longer length of stay (5.8 vs. 3.6 days, P<0.001), infectious complications rate (2.6% vs. 1.8%, P<0.001) case fatality rate (1.5% vs. 0.2%, P<0.001) and total charge-admission. An estimated $741.5 million in total hospital charges resulted from admissions in which a negative appendectomy was performed. Hence NAR has been recognized as a quality metric in the management of acute appendicitis.

The histological criterion for the diagnosis of acute appendicitis is polymorphonuclear leucocytic infiltration of the muscularis mucosa. The incidence of primary chronic appendicitis as a pathologic or clinical entity has been greatly disputed. Much more frequently recurrent acute attacks may be inappropriately referred to as chronic appendicitis.[10] Extensive fibrosis of the appendiceal architecture implies a chronic inflammatory reaction within the wall, supports the diagnosis of chronic obliterative appendicitis. The appendectomy resolves the chronic appendicitis.

CONCLUSION

Authors found maximum case in age group 21-30 years with male predominance. Maximum cases found to be of carcinoids tumor.

Body mass index, waist hip ratio and body fat percentage as early predictors of pre-diabetes and pre-hypertension in adolescents.

Ramya HS[1], Goutham AS[2], Pragyee D[2]

[1]Assistant Professor, Department of Pediatrics, KIMS Bangalore, India.
[2]Postgraduate Students, Department of Pediatrics, KIMS Bangalore, India.

Abstract

Objective: The study aimed to assess the relationship between Body mass index (BMI), body fat percentage(BFP) and waist hip(WH) ratio in predicting Pre-Diabetes and Pre-Hypertension.

Methods: A total of 389 adolescents aged 11–17 years were recruited from Doddaballapura government school. Body Mass Index and Waist Hip Ratio were determined using standard equipment's. Body fat percentage was derived from a body fat analyser. Fasting blood glucose was determined by glucometer method, Blood pressure was recorded using sphygmomanometer.

Results: Compare to students with normal BMI, those who are overweight had 7.19 times [95% CI: (2.25-22.96)] high odds to have pre hypertension or hypertension. Similarly compare to normal BMI students, obese students were 28.76 times high odds [95% CI: (2.5-330.27)] to have pre hypertension or hypertension. There was no significant difference between normal BMI students and underweight students in terms of Pre hypertension/ Hypertension. Compare to students with normal WH ratio, low WHR students didn't have any significant correlation in developing Pre hypertension or hypertension. Compared to students with normal Body fat percentage, those who had a high BFP were 6.02 times high odds to have pre hypertension or hypertension similarly those who had very high BFP were 21.25 times high odds to have pre hypertension or hypertension in respect to predicting pre diabetes, BMI and waist to hip ratio were not significantly correlated, whereas high Body fat percentage had 1.46 high odds as compared to normal BFP.

Conclusion: These data suggest the importance of the BMI, Body fat percentage and waist to hip ratio in adolescents, in prevention and early intervention of Obesity, Hypertension and Pre-diabetes since it may be the most cost-effective way of reducing the complications related with them.

Introduction

The unabated rise in the prevalence of overweight in children and adolescents is one of the most alarming public health issues facing the world today [1]. Among Indian children, various studies reported the magnitude of overweight to be from 9 to 27.5% and that of obesity from 1 to 12.9% [2-6]. Obesity increases the risk for many chronic diseases including diabetes mellitus, cardiovascular disease and non-alcoholic fatty liver disease, which, further decreases the overall quality of life [7-9]. Therefore, it is imperative to identify the individuals at risk at an early stage. Increasing evidence suggests that this epidemic of childhood obesity as a causative agent for premature onset of hypertension, resulting in, increased risk for adult coronary heart diseases [10,11]. The landmark Global Burden of Disease Study showed that the hypertension is leading the list of risk factors for death and disability worldwide [12].

Since the late 1990s, both the World Health Organization

(WHO) and the National Heart, Lung, and Blood Institute (NHLBI) have proposed that abnormal body weight be classified according to the body mass index (BMI) and body fat distribution, measured by the abdominal circumference (AC) or the waist circumference (WC) [13,14] It is widely accepted that being overweight, traditionally defined as having a body mass index 25 kg/m², is a major risk factor for a wide range of chronic diseases and injuries including cardiovascular disease (CVD), type II diabetes and certain site specific cancers including colorectal and breast cancer [15,16]. A recent report from the Prospective Studies Collaboration, which was based on 466 000 deaths, estimated that optimal survival is achieved at a BMI of 22.5–25 kg/m² with reductions in life expectancy of 3 and 10 years in individuals with moderate (BMI 30–35 kg/m²) and extreme obesity (BMI 40–50 kg/m²), respectively, the latter being equivalent to the years lost by lifetime smoking (Prospective Studies Collaboration, 2009) [17-20].

Although some cohort studies have shown that the higher the BMI, the greater the likelihood of developing hypertension in adults, The WHO recommends the use of the AC, taken at half-distance between the iliac crest and the lower rib cage rim, on the horizontal plane as a measurement of obesity [17-23]. However, the NHLBI prefers using the WC, measured at the highest portion of the right iliac crest as an indicator of obesity. The guide for identification and treatment of obesity in adults, published in 1998, refers to several prospective studies showing that abdominal fat correlates with increased mortality rate and risk for diabetes, hyperlipidemia, hypertension, coronary artery disease and cerebral and peripheral disease [24]. In spite of the need to establish cut off points of WC/AC for risk prediction of obesity related complication in children and adolescents, this was not proposed until 2004, although some articles reported percentile distributions in different populations [25]. So far, the cut-off points proposed for adults by the NHLBI7 were used, with 88 centimetres for women and 102 cm for men as standards.

Paediatric hypertension is increasing along with the paediatric obesity epidemic. Blood pressure measurement neither have been included in elementary school children health examination schedule, nor have blood pressure check-up been required during paediatric medical visits in India. This has led to under diagnosis of paediatric hypertension in clinical settings [26]. Hypertension is classified as essential (primary) or secondary to underlying cause, e.g. disease of renal parenchyma, reno-vascular or endocrine disorders. Screening studies suggest that essential hypertension is in increase trend during late childhood and adolescence. There is increasing evidence that essential hypertension tracks into adulthood, resulting in considerable cardiovascular morbidity [27]. The objective of this present article was to assess the sensitivity and specificity of anthropometric body fat measurements in predicting hypertension and pre diabetes in a sample of school going children of Karnataka.

Materials and Methods

Study Design and Size

A cross sectional study was carried out in Doddaballapura Government school, Karnataka, in December 2015, by Department of Paediatrics of Kempegowda Institute of Medical Sciences. A total of 389 students comprising of male and female adolescents, aged 11 to 17 years. Children with chronic disease like renal, hepatic or endocrine disorders or taking treatment for the same were excluded.

Data Collection Procedure

An informed consent was taken from all the subjects/ Principal of the school and institutes ethics committee permission was obtained. School was visited 1 day prior to the pre-arranged date and instructed for overnight fasting.

Anthropometric Parameters

The study protocol included anthropometric parameters, body weight, height, waist circumference (WC) and hip circumference (HC). Adolescents weight was measured (to the nearest 0.5 kg) with the child standing motionless on the weighing scale with feet 15 cm apart and weight equally distributed on each leg. Height was measured with adolescent being bare foot (to the nearest 0.5 cm) with the child standing in an erect position against a vertical scale of portable stadiometer with the participants feet placed together with heels, buttocks and shoulder blade against the stick head positioned in Frankfurt horizontal plane. Waist circumference was measured with a non-stretchable tape (exerting the same standard pressure on the tape) at the midpoint of the lowest rib cage and the iliac crest, to the nearest 0.1 cm. Hip circumference was measured at the level of greater trochanters with the subject in standing position and both feet together. For all measurements, tape was positioned parallel to the floor.

BMI was computed by dividing weight (kg) by height square (m²). BMI categories were defined as (a) Normal weight, (b) Overweight and (c) Obese according to contemporary Indian data. Height for age, weight for age and BMI for age z-scores were computed using Indian reference data [28].

Blood pressure was measured on left arm by auscultatory method using mercury sphygmomanometer. The individual was made comfortable and seated at least for five minutes in the chair before measurement. Hypertensive and Pre-Hypertensive children considered and were checked again half an hour apart and the average of two reading was taken. Pre-Hypertension and Hypertension are diagnosed if Systolic or Diastolic blood pressure or both are >90th to <95th and >95th centile as per age and height, respectively.

Fasting plasma glucose was measured with One Touch Glucometer (Johnson & Johnson Co.) in all the subjects after an overnight 10 h fast. Later students were provided with breakfast. Pre-diabetes was defined as fasting plasma glucose between 100 mg/dl to 125 mg/dl.

Body fat percentage was measured using commercially available digital monitor Omron HBF-306 body fat monitor incorporating bioelectrical impedance(BI) analyser.

Statiscal Analysis

Data were analyzed using SPSS version 19.0.Data was expressed as mean +/- SD for quantative variables or numbers and percentage for categorical variables. Data was compared using student t-test for 2 groups and ANOVA for more than 2 groups. Multivariate regression analysis was done to estimate effect of each variable on obesity. For all test p value<0.05 was considered statically significant.

To detect the Sensitivity and Specificity of each anthropometric parameter to detect Prehypertension and Pre-diabetes ROC curve was plotted.

Results

In the present study, total 389 adolescents investigated, 45% were girls and 55% were boys (Tables 1 and 2).

The area under the curve for waist hip ratio, waist circumference, hip circumference, weight, body fat and BMI are 0.54, 0.43, 0.43, 0.43, 0.48 and 0.42, respectively. Of these values the waist hip ratio which had relatively higher area under the curve, at the cut of 0.84, it has 61% sensitivity and 54% specificity in suspecting an individual for pre-diabetes (Table 3 and Figures 1-3).

The area under the curve for waist hip ratio, waist circumference, hip circumference, weight, body fat and BMI are 0.43, 0.46, 0.54, 0.60, 0.60 and 0.66, respectively (Table 4 and Figure 4) for hypertension in boys.

The area under the curve for waist hip ratio, waist circumference, hip circumference, weight, body fat and BMI for hypertension in girls is 0.54, 0.69, 0.79, 0.81, 0.79 and 0.78, respectively (Table 5 and Figure 5).

Interpretation

Compared to students with normal BMI, those who were overweight had 7.19 times [95% CI: (2.25-22.96)] high odds to have pre hypertension or hypertension (Table 6).

Similarly compared to normal BMI students, obese students were had 8.76 times high odds [95% CI: (2.5-330.27)] to have pre hypertension or hypertension.

There was no significant difference between normal BMI students and underweight students in terms of Pre hypertension/Hypertension.

Compared to students with normal WH ratio, low WHR students did not have any significant correlation in developing pre-hypertension or hypertension.

Compared to students with normal body fat percentage, those who had a high BFP had 6.02 times high odds to have pre-diabetes or diabetes similarly those who had very high body fat percentage who were at 21.25 times high odds to have pre-diabetes and diabetes (Figure 3).

Discussion

Vague was first to realize that different body morphology or types of fat distribution were related to various risks associated with obesity [29]. Our study comprising of 214 males and 175 females showed the prevalence of overweight and obesities among preparatory adolescents in government school of Karnataka was 3.9% and 0.8%, respectively.

There is a high incidence of Diabetes in India which is increasing rapidly. International Diabetes Association has estimated that there would be around 70 million cases of Diabetes mellitus in India by the year 2025 [30,31]. Also, studies have shown that diabetes sets in a decade earlier in Indians than West [32]. Abnormal anthropometric indicators like WHR and BMI are associated with a

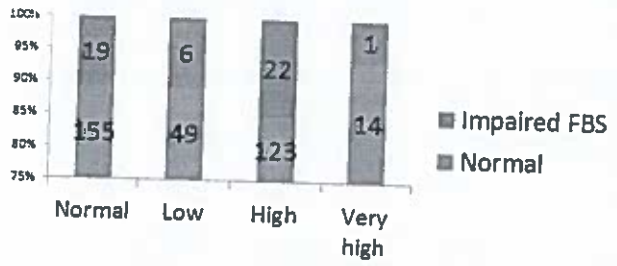

Figure 3. Body fat with FBS status

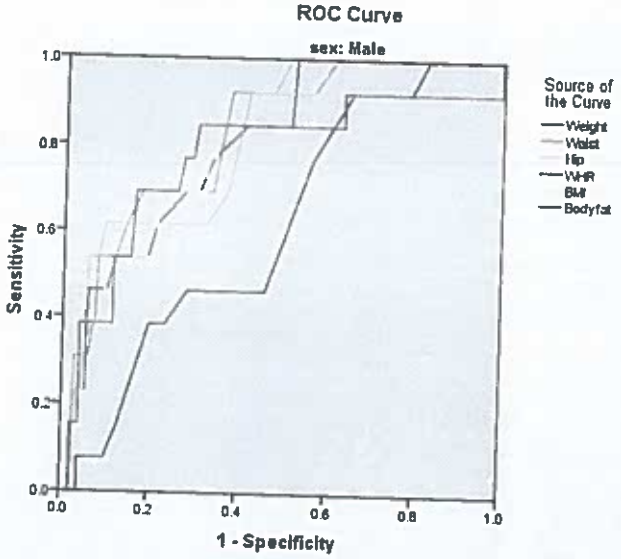

Figure 4. ROC curve for pre-hypertension for boys

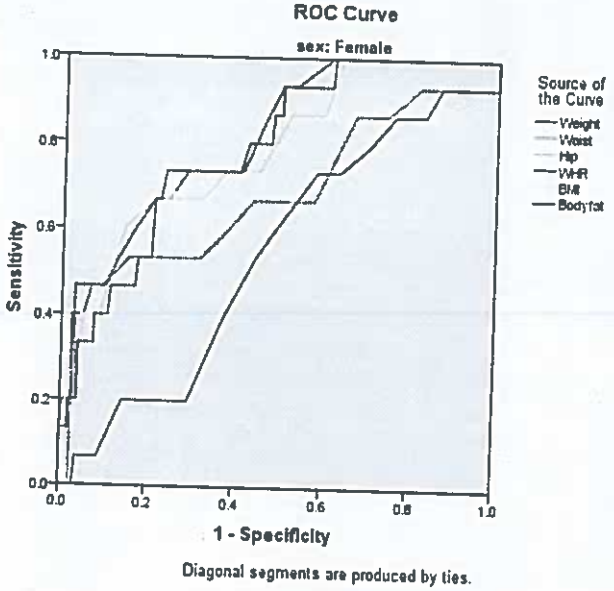

Figure 5. ROC curve for pre hypertension among girls

greater possibility of development of DM and metabolic syndrome. Students having a WHR of more than 0.8 were categorised as having high WHR. However, cut-off values of WHR are not prescribed by WHO for children. But previous studies have shown WHR values for children whose weight for age was between 50th to 97th percentile

Table 6: Similar studies

Study	Year of Study	Place of Study	Prevalence of Hypertension in Obesity
Gupta et al. [42]	1990	India	0.34%
Verma et al. [36]	1994	Punjab, India	13.7%
Anand et al. [37]	1996	Amritsir ,India	0.23%
Macedo et al. [38]	1996	North Portugal	5.2%
Sorof et al. [39]	2002	Texas, USA	19.4%
Present study	2015	Banglore, India	7.2%

were between 0.8-0.9, which is closer to the WHR cut-off values for adults as per WHO guidelines [33]. In our study, number of students with high waist-hip-ratio especially was 11.1% (43 participants). Significant correlation was found between WHR and pre-diabetic status (p value=0.07) (Table 6). As overweight condition and obesity are risk factors for diabetes, a high waist measurement and a high WHR might serve as a good indicator in recognizing cases at high risk that might progress to pre-diabetic state and later Diabetes mellitus. No correlation was found between pre-diabetes with overweight or obesity. This might be due to the fact that insulin resistance is a common feature even in non-obese Asian Indian subjects with a specific "Asian Indian Phenotype" that refers to certain unique clinical and biochemical abnormalities in Indians which include increased insulin resistance, greater abdominal adiposity, i.e., higher waist circumference despite lower body mass index, lower adiponectin and higher high sensitive C-reactive protein levels. This phenotype makes Asian Indians more prone to diabetes and premature coronary artery disease. At least a part of this is due to genetic factors. This observation is also in accordance with the study done by Narayanappa et al. [32,34,35]. However, the primary drive for the epidemic of diabetes is the rapid epidemiological transition associated with changes in dietary patterns and decreased physical activity as evident from the higher prevalence of diabetes in the urban population which in recent times is also seen in rural areas.

At third screening, a total of 28 cases (7.2%) had abnormal blood pressure of which 5.1% were in pre-hypertension group and 2.1% in hypertension. The prevalence in various other studies ranged from 0.46% to 19% as shown in. This wide difference could be due to different standards used for the diagnosis of hypertension and also, due to variations in the regions. Also, there is higher prevalence of hypertension in southern India probably because of influencing factors like genetic inheritance, dietary habits and lifestyle factors.

According to NHBPEP, pre-hypertension defined if BP is between 90th and 95th percentile. Stage I hypertension is BP from 95th percentile to <99th percentile plus 5 mm of Hg. Stage II hypertension is BP more than 99th percentile plus 5 mm of Hg. Prehypertension and stage I hypertension need only weight and dietary management. Stage II hypertension needs pharmacological therapy in addition to weight and diet management. Our cases were managed accordingly.

Anthropometric Risk Factors

Pre-hypertension and hypertension were directly proportional to weight for age ($p<0.05$). Also it was noted that, high body fat had significant association to incidence of pre hypertension and hypertension. Hypertension in obese children could be due to increased cardiac output, increased blood volume, excessive sodium intake, increased steroid production and alteration in receptors for various presser substances [40].

Body mass index and increased weight and height had a significant association with hypertension in our study ($p \leq 0.001$), similar results obtained in Anand et al. [37] Chadha et al. [40] study. The results also showed that lower the BMI, lessen the chances of hypertension. Obesity in childhood is a well-established risk factor for hypertension. In our study, prevalence of HTN in obese children is 11.1% which is statistically significant. Sorof et al. [39] Verma et al. [36] have shown that 19.4% and 13.7% of obese children had hypertension, respectively.

No association was found between waist hip ratio and hypertension, it correlates with studies done by Chaddha et al. and Moussa et al. [40,41].

Limitations

The sample size in the present study was small and there are no standard charts available for the local population from which the sample has been taken. Blood pressure is also influenced by various other factors such as ambience, fasting vs. non fasting state, psychological stress, which could not be controlled in our study.

Recommendations

Regular anthropometric and blood pressure monitoring at least once in a year on an outpatient basis or in routine school health check-up should be incorporated in early life.

Serial blood pressure measurements are required to diagnose hypertension than single reading and children with significant clinical history should be screened at the earliest.

Studies involving a larger population are required to prepare standard centile charts for the local population.

What is Already Known?

Extensive studies have been done to establish relation between waist hip ratio with pre-hypertension and prediabetes in western country. These studies correlate faulty food habits and sedentary lifestyle with obesity associated comorbidity.

What this Study Adds?

So far very few similar studies have been done in school going children in India, and study in rural parts of India are very rare. Among the studies which are done, many of them do not include BMI, Waist hip ratio and Body Fat percentage all together to correlation for pre-hypertension and pre-diabetes in a single subjected population sample. Our study establishes this relation in school going children of rural part of Karnataka. It was an extensive study which concluded BMI, Waist hip ratio and Body Fat percentage are early Predictors of Prehypertension and hypertension. Our results are comparable to studies done in urban scales. Early incidence can prevent this epidemic rise in obesity and associated comorbidities in new India.

Conclusion

Hypertension and Diabetes is a significant problem in the school going adolescents of developing countries. Obesity, waist hip ratio, and increased body mass index are significant anthropometric risk factors for hypertension and diabetes. Using simple screening methods in younger ages itself like measuring BMI, Waist and FBS, it is possible to identify individuals at high risk at an early age and accordingly lifestyle modifications can be adopted to postpone the onset of the disease and reduce the burden on the community and the nation.

ABSTRACT

Aim

To study relation between serum magnesium levels and febrile convulsion and to compare serum magnesium level in children with febrile convulsion.to febrile children with no convulsion.

Material and Methods

A prospective case control study done in Kempegowda Institutes of Medical science, Bangalore between October 2015- October 2016 where 2 groups were made of 45 children each as case and control group. Informed consent was taken by all parents and detailed history, past , birth and family history was taken and serum magnesium levels were done by Roche 9180 electrolyte analyser.

Results

Mean age of cases with febrile convulsion and febrile patients without seizures were 1.97years (+/-) 1.33years and 2.01years (+ /-)1.02 years respectively. there were 24 male and 21 female babies in group 1 and 23 male and 22 females in other group. the mean age and sex were similar in both groups. Mean level of magnesium were 1.97+_0.24 and 2.19 +_ 0.20 in cases with febrile convulsion and febrile patients without seizures respectively and there was significant differences.

Conclusions

Febrile convulsion is the most common type of convulsion in children. We got a positive co relation between levels of serum magnesium and febrile convulsion. However more studies at a larger level required to establish a strong correlation between the two.

KEYWORDS: *Serum Magnesium Levels, Febrile Convulsion & Convulsion*

Received: Feb 10, 2017; **Accepted**: Mar 03, 2017; **Published**: Mar 11, 2017; **Paper Id.**: TJPRC:IJGPMJUN20172

INTRODUCTION

Febrile convulsion are the most common type of seizures and occur in 2-4 % of children [1] Factors like genetics, neurotransmitters level changes and few trace elements have been introduced as a possible cause [2-4], however, the main cause not known yet. Because 30-40% of children who experience a febrile convulsion will have a recurrence, it makes febrile convulsion an important issue to understand and prevent [5]In the past, blood tests like electrolytes were not suggested, but recently several studies have shown the effect of GABA, ZN, and Fe in developing febrile convulsion offering possible interference of other trace elements. Magnesium is the fourth most common cation in the body and the third most intra cellular cation .50-60% of body magnesium is in bone where it serves as reservoir because 30% is exchangeable, allowing movement to extra cellular space. Most intra

cellular magnesium is bound to protein, of about 25% is exchangeable. Because cells with higher metabolic rate have higher magnesium, most of it is present in muscle and lever. The normal plasma magnesium is 1.5-2.3 mg/dl. Magnesium is essential for membrane utilization and nerve conduction [1].By definition by AAP criteria , the child should have a febrile illness or certainly fever, neurologically healthy between 6 month to 5 years of age whose seizure is brief (<15min) , generalized and occurs only once (simple febrile convulsion) or more times(complex febrile convulsions) during a 24 hour period during a fever[6].The following objectives to correlate the hypothesis , to find co relation between serum magnesium level and febrile convulsion and to compare level of serum magnesium between children with febrile convulsion and febrile children with no convulsions.

METHOD

This was a prospective case-control study done in Kempegowda Institute of Medical Science, Bangalore between October 2015 to October 2016 which included two groups of patients with 6-60 month of age with febrile convulsion and fever without seizure respectively. Forty five cases were enrolled in each groups.

Inclusion Criteria

- Patients between 6 month to 5 years of age of either sex.

Exclusion Criteria

- Electrolyte imbalance due to gastrointestinal disease
- CNS infections (encephalitis , meningitis)
- Metabolic disorder

Detailed history of presenting complaints, type and duration of seizure, past history, birth history and family history was taken . Thorough physical examination was done. Children with congenital or acquired illness were excluded. 2ml of blood was drawn under aseptic precaution and serum magnesium level were measured using Roche 9180 electrolyte analyser. The analysis was done by STATA11.1, data were analysed using T test and Chi square

RESULTS

Mean age of cases with febrile convulsion and febrile patients without seizures were 1.97years +_ 1.33 years and 2.01years + _ 1.02 years respectively. There were 24 male and 21 female babies in group-I and 23 male and 22 females in group-II. The mean age and sex were similar in both groups.

Mean level of magnesium were 1.97+_0.24 and 2.19 +_ 0.20 in cases with febrile convulsion and febrile patients without seizures respectively and there was significant difference (p=0.001)

Table 1

VARIABLE	GROUP 1	GROUP 2
Serum Mg	1.97+_0.24	2.19 +_ 0.20

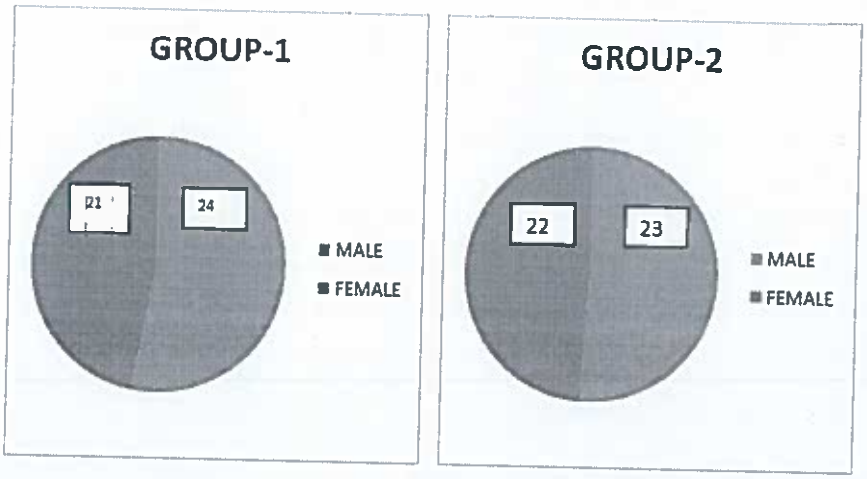

Figure 1

DISCUSSIONS

Action of magnesium level on nervous system is that, it reduces the release of acetyl choline at the neuromuscular junction by antagonizing calcium ions at presynaptic junction, reduced excitability of nerves, and acts as anticonvulsants, reverses cerebral vasospasm [7].It is suggested that alteration in magnesium concentration in plasma and intracellular matrix give rise to functional impairment of the cell membranes, which might trigger seizures. Recent evidences indicate that the deficiency of magnesium play a significant role in febrile convulsion [7, 8].Magnesium plays an important role in establishing electrical potential across cell membrane. It also affects calcium metabolism the production of cyclic adenosine monophosphate is magnesium dependent which in turn controls release of parathyroid hormone. [7, 9]. Our study showed difference in magnesium level in between two groups which is similar to Studies done by Prakash, Talebian and Sadinegad [10-12]. However studies done by Burhanoglu, Donalson, Rutter and Heipertz showed no difference in magnesium level [3, 13-15].A recent study done in Egypt in 2013 in Ain Shams University and National research centre Egypt to asses blood levels of trace elements in familial febrile convulsion concluded that serum selenium and magnesium levels were significant low and logistic regression model in their study showed that selenium and magnesium have protective effect in children with febrile convulsion [16].

CONCLUSIONS

Febrile convulsion is the most common type of convulsion in children. In our study, a positive correlation was found between levels of serum magnesium and febrile convulsion. Hence children with low serum Magnesium level are more prone to get febrile convulsions than children with normal Magnesium levelsHowever more studies at a larger level required to establish a strong co relation between the two.

Prevalence of attention deficit hyperactivity disorder in school going children aged between 5-12 years in Bengaluru.

Ramya HS[1], Goutham AS[2], Lakshmi V Pandit[3]

[1]Assistant Professor, Department of Pediatrics, KIMS Hospital Bangalore, India.
[2]Postgraduate, Department of Pediatrics, KIMS Hospital Bangalore, India.
[3]Professor, Department of Psychiatry, KIMS Hospital Bangalore, India.

Abstract

Background: Attention deficit hyperactivity disorder (ADHD) is one of the most common childhood psychiatric disorders that affect 2% to 14% of school age children. It is characterized by age inappropriate level of inattention with or without motor over activity and impulsivity in academic and social spheres. Boys are more affected than girls and male female ratio is 4:1. Although ADHD is the most common condition, the evidence from Indian studies is very less. Many studies are required in India to see the magnitude of ADHD. Evaluation of the prevalence of this condition in our country will help clinicians to consider the diagnosis of ADHD and related disorders. This study aims to determine the prevalence of ADHD among school going children (5 years to 12years) and to know the difference between government and private schools as well as to determine male to female ratio in Bengaluru.

Methods: This was a cross-sectional study done in Bengaluru city by convenience sampling method. A total 18 schools comprising of both private and government were selected. 3120 Children aged between 5-12years studying in these schools were included in the study. Introduction about ADHD was given by Paediatrician to the teachers followed by screening for ADHD was done by teachers using Conner's teachers rating scale for all children. Positive cases in these were screened with Parents and Paediatrician by using Conner's parent rating scale. Children who were positive in Parents and Paediatrician rating scale were interviewed by the Psychiatrist at KIMS Hospital and ADHD was diagnosed by using DSM V criteria along with IQ assessment and treatment was started for the needy.

Results: The prevalence of ADHD in our study was 1.3%. Male to female ratio was 1.6:1. Among the positive cases, children belonging to Hyperactivity type were 34.1%, inattention was 9.8% and combined type was 56.1%. Prevalence in private school was 1.25% and government school was 1.37%. Total dropouts were 2.5% who did not reach the hospital for the final diagnosis.

Conclusion: ADHD is prevalent worldwide and it is also one of the emerging disorders in our country. It constitutes a significant mental health disorder in children and 50% of this disorder will be carried to adulthood. In our study we had prevalence of 1.3% ADHD and 2.5% dropouts due to lack of awareness of this disorder, their work pressure, distance, social and financial constricts. It is high time to identify the disorder and creating wide spread awareness about ADHD by the Paediatrician's among the Teachers, Parents and Primary care Physicians, in order to prevent the social and academic impact of the disorder. By introducing an ADHD standard screening methods in all schools along with the regular health check-ups will bring awareness in the society for the healthy future of the children. Lastly every school should have a counsellor to overcome ADHD and other related problems.

Accepted April 20, 2017

Introduction

Attention Deficit Hyperactivity Disorder (ADHD) has been described all around the world and is the most common neurobehavioral disorder of childhood and one among the most common chronic health conditions affecting school-age children [1,2]. It is characterized by inattention, increased distractibility with difficulty sustaining attention, poor impulse control and decreased self-inhibitory capacity, motor over activity and motor restlessness [3].

The first example of a disorder that appears to be similar to ADHD was given by Sir Alexander Crichton in 1798. George still, conducted study on a group of 20 children whom he described as having a deficit in "volitional inhibition [4]. He reported that there was an overrepresentation of male subjects, a family history of alcoholism, criminal conduct, and depression, a family predisposition and the possibility that the condition may arise from an injury to the nervous system. Still's observations are quite common and have been corroborated in later research.

Later, it was stated that mild forms of brain damage in infancy, although unnoticed at that time, could lead to behavioural sequelae, which becomes first apparent at school [5,6].

In 2008, it was defined as a "persistent pattern of inattention, hyperactivity and impulsivity, that is more frequent and severe than is typically observed at a comparable level of development" affecting approximately 5% of school-age children and frequently persisting into adulthood [7-9].

Population surveys suggest that ADHD occurs around the world in about 5% of children and it is carried to about 2.5% of adults. These reported rates vary depending upon the nature of the population sampled and the method of ascertainment [3]. Many studies across the globe have reported the prevalence of ADHD in 5% to 10% of school aged children. Most of them are western studies and there is a little information about the same from India.

ADHD is often undiagnosed in children. This is usually due to lack of awareness of ADHD among parents and teachers. Children with ADHD have difficulty in performing scholastically to their optimum levels. This translates to stress on the family and in turn has an emotional impact on the child. Hence, there is an urgent need for continued teamwork on prevalence of ADHD in our country.

This study provides the much needed epidemiologic data on ADHD as well as understands the influence of socioeconomic factors in the same which in turn would help in designing the programme to increase the awareness of ADHD in parents as well as teachers.

This study also helps in differentiating the prevalence of ADHD between Private and Government schools by including the socio-economical and educational factors causing impact on children's mental health. Finally, this study will throw light on the male female ratio in the prevalence of ADHD.

Aims and Objectives

1. To study the Prevalence of ADHD in children aged 5-12 years in urban schools of Bengaluru.

2. To compare the Prevalence of ADHD in Government and Private Schools.

3. To create awareness among the teachers and parents about ADHD in children.

Materials and Methods

Study Area

The study was conducted in Bengaluru South block schools.

Study Design

Cross sectional-descriptive.

Study Duration

Time period of two year, i.e., October 2014 to October 2016.

Study Population

School children in the age group 5 to 12 years in Bengaluru city.

Exclusion Criteria

- Children <5 years and >12 years.
- Children with conduct disorders and oppositional disorders.
- Children studying in schools outside Bengaluru city limits.

Statistical Analysis

Descriptive statistics-percentages and proportion.

Ethical Clearance

The study protocol was submitted to the ethical committee of Kempegowda Institute of Medical Sciences and clearance obtained before the study was commenced.

Method of Collection of Data (Including Sampling Procedure)

Sampling procedure: Convenience sampling

Sample size: N=3120, Sample size has been calculated taking prevalence of ADHD among school going children as 5% at 5% significance level and 10% allowable error.

Collection of Data

The collection of data was done in 4 phases. These rating

scales assist in determining whether children between the ages 5 to 12 years might suffer from ADHD. Details are presented in presented in supplementary file.

Study Instruments

Semi-structured Performa was prepared after discussion with the psychiatrist. It is a questionnaire with 12 simple questions from DSM-V criteria related to the ADHD symptoms. It has 6 questions related to inattention, 6 questions related to hyperactivity and impulsivity. It was translated to kannada for easy understanding and use in kannada medium schools.

Conner's Rating Scale, Revised (CRS-R): Developed by C. Keith Conners, Ph.D., CRS-R is used as part of a comprehensive examination and is designed to be easily administered and scored. CRS-R is the widely used rating scale and has set the standard for assessing ADHD and related problems. CRS-R is available in long and short versions for both parents and teachers. Short version (each comprising of 27 items) of both parent and teachers rating scale was used in our study.

Based on the types of symptoms, three kinds (presentations) of ADHD can occur:

1. Combined Presentation: if enough symptoms of both criteria inattention and hyperactivity-impulsivity were present for the past 6 months

2. Predominantly Inattentive Presentation: if enough symptoms of inattention, but not hyperactivity-impulsivity, were present for the past six months

3. Predominantly Hyperactive-Impulsive Presentation: if enough symptoms of hyperactivity-impulsivity but not inattention were present for the past six months.

Results and Observations

We found 41 children with ADHD, which translates to a prevalence rate of 1.3 % in school going children of age group 5 to 12 years. The prevalence was 1.6% in boys and 1% in girls.

The above Table 1 also shows the sex distribution of the children screened which was 56.7% boys and 43.3% girls (1.30:1) whereas the boys: girl ratio among ADHD children is 1.6:1 and is significant (p value<0.001).

Table 2 shows the prevalence of ADHD in different age groups. The prevalence is highest in 6-8 years group and lowest in 5 years age group. The prevalence tends to decrease as age progresses.

Figure 1 shows the prevalence of ADHD subtypes in our study sample. In this study, the prevalence of hyperactivity subtype was 34.1%, the inattention type was 9.8% and combined type was 56.1%. Combined type was more predominant in our study closely followed by hyperactivity type.

Table 3 shows distribution of ADHD children based on different subtypes of disorder. In children of 5 years prevalence of ADHD is 7.14%. The hyperactivity type is 2.38%, combined type is 4.76% and inattention type is 0%. In children of 6-8 years prevalence of ADHD is 1.06%. The hyperactivity type is 0.47%, combined type is 0.35% and inattention type is 0.23%. In children of 9-10 years prevalence of ADHD is 0.96%. The hyperactivity type is 0.35%, combined type is 0.52% and inattention type is 0.09%.

In children of 11-12 years prevalence of ADHD is 1.65%. The hyperactivity type is 0.46%, combined type is 1.10% and inattention type is 0.09%.

This Table 4 shows that in our study 53.66% of the children with ADHD belonged to Government school, 46.34% to private. The difference was not significant in statistical analysis.

This Table 5 shows the academic performance of children who were diagnosed to have ADHD. This academic

Table 1. Prevalence rate of ADHD by gender

ADHD	Gender		Total
	Female	Male	
No	1337 (99%)	1742 (98.4%)	3079 (98.7%)

performance was based on the marks obtained in the tests and exams in school. Out of 41 children only 31 children were having average grades and 10 children having poor grade, none of them were having good grades.

Discussion

Our study shows 1.3% prevalence of ADHD. Other studies which have prevalence of 2-15% Dropouts were 2.56%. Among these, most of them were having significant scores in Teachers, Parents and Pediatrician's scale and were unavailable for follow up at the KIMS hospital. The probable reasons behind this is lack of knowledge and false beliefs about ADHD in our country and in a metropolitan city like Bengaluru, many could not approach us to the hospital during working hours for final follow up with all their work pressure, distance, social and financial constricts.

This study examined the prevalence of ADHD in 3120 school age children of age group 5 to 12 years by cross sectional survey in Bengaluru city in Karnataka. Although the prevalence of 1.3% is low when compared with the studies in western countries and some studies in India, it is consistent with some Indian studies in school age children [3,10,11].

A review of 17 studies conducted in all continents showed a wide range of prevalence ranging from 0.2% to 23%. These studies were done using different criteria (DSM and ICD) and strategy adopted to collect information were different (i.e., only parents or teacher or both, whether functional impairment required, whether child was interviewed). Studies based on information from either only parents or teachers have higher prevalence than the studies which collect information from both parents and teachers, which in turn will be higher compared to studies which includes interview in addition to the information from both parents and teacher

According to Kurtzke et al., epidemiological studies with a higher prevalence should be considered as estimated or screening prevalence because many false positives may be included. That may explain part of the differences observed between the results obtained from different studies [12].

More recent community based epidemiological studies have reported much lower prevalence figures. The Great Britain office of national statistics conducted a survey of more than 10,000 children and found a DSM-IV based prevalence of 1.4% in 1999 and 1.5% in 2004. A similar profile is seen in recent studies conducted in developing countries. In Brazil DSM-IV based prevalence of 1.8%, 2% in Bangladesh and 1.6% in India were noted. In our study, the prevalence is 1.3% and is consistent with these recent studies. [13].

Epidemiological surveys in western countries have reported a greater incidence in boys than in girls; the ratio ranging from 2:1 to 10:1 [14,15]. Whereas Indian studies have reported ADHD to be 3.3 to 7.7 times more common in boys than girls.

Our study gives the sex ratio of 1.6:1 which is (low) compared to above studies, but a recent meta-analysis of studies done in last decade gives a pooled prevalence of (2.4:1) which is consistent with the present study [16].

According to Goodman et al. [16] the gender differences strengthens the evidence for a biologically based, often genetically transmitted etiology of hyperkinetic disorder.

This difference may be due to the fact that girls have ADHD with higher predominance of inattention type, causing less trouble to the family and at school, and are therefore less easily identified.

Our study shows higher prevalence in the age groups 11-12 years. This is consistent with the findings of Mullick et al. [17] which also showed a higher prevalence of ADHD in age groups 9-10 years and 11 to 12 years. This difference may be due to increased demands of attention both in school as well as home as the child grows.

In our study, ADHD was associated with poor academic performance in 24.4%, average performance in 75.6% and none in good performance (based on marks obtained in tests and examinations). This is in accordance with the fact that there is functional impairment in children with ADHD.

Our study shows higher prevalence of ADHD among children whose mothers were homemakers and is not consistent with the hypothesis that homemakers are in a better position to look after their children at home both socially and psychologically [18].

High proportions of mothers in this study were either had primary education or illiterate, which puts more weight on education as a contribution factor. ADHD is one of the best investigated child mental health disorders. ADHD has received a great deal of clinical, scientific and public attention in recent years. In the last decade, western literature on this syndrome has grown but in India only a few studies have been done. Hence this study was done to fill this void.

There is lack of awareness about ADHD in parents, teachers and even among treating clinicians to create necessary awareness about ADHD, study results were discussed in parent – teacher meet conducted monthly in the school. Early detection and intervention about ADHD were explained. Teachers were also trained on classroom management of ADHD children.

Conclusion

Our study aim was to find the prevalence of ADHD among 5-12years old school going children in Bengaluru. We found a prevalence of 1.3% with male: female ratio of 1.6:1. Although the prevalence in our study is low compared to studies in western countries and also some Indian studies, it still constitutes a major public health problem. Epidemiological survey of ADHD is important in planning health services. Therefore further interview based studies assessing the prevalence of ADHD as defined by DSM-V criteria are required in different parts of the country to get a clearer picture of its burden in our country. The knowledge of ADHD is lacking in teachers, parents and also in the society, by this study we would like to recommend the ADHD screening should be done regularly along with routine health check-ups done annually in every government and private school, counsellors should be there in every government and private school to help students to overcome these type of issues.

ABSTRACT

Background: Childhood obesity is a rising epidemic and a major public health problem with the risk for type 2 diabetes mellitus, hypertension and cardiovascular disorders in later life. Neck circumference (NC), a marker of upper body subcutaneous adipose tissue distribution can predict higher metabolic risk. The aim of the present study was to evaluate the association between neck circumference (NC) and obesity.

Methods: This cross-sectional prospective observational study was conducted in Bangalore in the month of October 2016. 172 male and 161 female students, aged 13-17 years were screened. Anthropometric markers of obesity measured included body mass index (BMI), waist circumference (WC), hip circumference (HC), waist-to-hip ratio (WHR), and compared with neck circumference (NC) of the same subjects. Pearson's correlation coefficient was calculated between neck circumference and other obesity indices, and receiver operating characteristic curve analysis was used to determine the best cutoff value of neck circumference in predicting high BMI.

Results: Overall, 13.2% boys and 9.9% girls were found overweight/obese. The mean BMI was 25.27±2.09kg/m^2 and25.17±2.23kg/m^2, mean neck circumference was 33.43±2.3cm and 31.50±1.4 in overweight/obese boys and girl respectively. All of the anthropometric parameters were found to be significantly higher in overweight/obese children than with their normal weight peers and higher in boys compared to girls. The neck circumference in boys was significantly greater than girls and higher in overweight/obese with P<0.001. The best cut-off value of neck circumference by ROC to identify boys with a high BMI was 32cm with sensitivity of (81.82%), specificity (89.06%), and for girls was 30cm with sensitivity of (84.85%), specificity (87.5%). Neck circumference had a strong positive correlation with other anthropometric measures BMI, WC, waist hip ratio in both boys and girls (p <0.001).

Conclusions: Neck circumference significantly correlated with other indices of obesity. It can be used with great reliability to screen overweight and obesity in children. NC can be considered as a simple, time saving and inexpensive clinical tool for detection of obesity in large population-based studies in children and adolescents.

Keywords: Body mass index, Neck circumference, Overweight, Obesity, Waist Circumference, Waist hip ratio

INTRODUCTION

The prevalence of childhood obesity is rapidly increasing worldwide. Obesity is associated with increased risk of cardiovascular and metabolic disturbances in later life. In children, the prevalence of obesity increased 300% over approximately 40 years. The National Health and Nutrition Examination Survey (2009-2010) found 32% of children between 2-19 year-old to be overweight or obese.[1]

BMI is the most widely used tool for defining overweight and obesity in both adults and children. But BMI is a suboptimal marker for total body fat and less suitable to

assess body fat distribution. Regional deposition of fat, especially in the upper body segment, is a better predictor of obesity related complications, such as hypertension, diabetes, and cardiovascular diseases.[2]

In assessing central obesity, anthropometric measures used are waist circumference (WC), waist/hip ratio (WHR), sagital abdominal circumference, etc, and skinfold thickness like triceps/subscapular skinfold thickness are measures of subcutaneous adiposity. But these measurements may not be of practical to use in winter and busy primary day to day practice. Other techniques like DEXA (dual-energy X-ray absorptiometry), USG, CT and MRI imaging procedures are expensive procedures to measure visceral/subcutaneous adiposity and are limited to research purposes. So there is a need to develop a simple, quick and reliable method of assessing obesity in primary care practices, to control obesity and related metabolic consequences. Free fatty acids release from upper body subcutaneous fat was found to be larger than that from lower body subcutaneous fat, a fact that further strengthens the relevance of measuring upper body subcutaneous adipose tissue depot.[3] Neck circumference measurement has been suggested as an index of the upper body fat distribution and can be used as a simple and time-saving screening measure to identify overweight/obesity.

The purpose of this study was to determine whether neck circumference alone can be used to identify overweight and obese children and to find out the correlation between neck circumference and BMI, WC, WHR to evaluate obesity.

METHODS

The present study was a prospective cross sectional observational study conducted in 2016 in the month of October in an urban school in Bangalore. After institutional ethical committee approval, we screened 333 children who were aged between 13 to 17 years. Parents were informed and consent was taken from the adolescent children in this study. Inclusion criteria were all adolescents aged between 13 to 17 years and who gave consent. Exclusion criteria were children with goiter, cervical lymphadenopathy or other neck masses, neck deformity, diabetes, cushings disease, medication use (like steroids etc) or procedures like tracheostomy or use of cervical collar were excluded from this study.

Anthropometric measurements

Measurements were taken by trained research assistant, height was measured by using a stadiometer, child standing with barefoot and head held in Frankfurt horizontal plane to the nearest 0.1 cm. Weight was measured by using a calibrated electronic weighing scale, to the nearest 0.1 kg. BMI was calculated by dividing weight in kilograms (kg) by the square of their height in meters (kg/m^2). WC was measured by using flexible measuring tape to the nearest 0.1 cm with the child standing, and at the end of normal expiration at a point midway between the inferior margin of the lowest rib and the iliac crest. Hip circumference (HC) was measured at the maximum circumference around the buttocks. WHR was calculated by dividing WC by HC. Neck circumference was measured by using a flexible tape, with the child in the standing position, head held erect and eyes facing forward and the neck in a horizontal plane at the level of most prominent portion, the thyroid cartilage.

Classification of BMI (WHO -2004): Underweight < 18.5 kg/m^2, normal 18.5 - 22.9 kg/m^2, over weight- 23 - 27.4 kg/m^2, Obese >_27.5 kg/m^2.[4] WHR values (WHO) for males was 0.9 and for females was 0.85.[5]

According to this classification 77 (23.1%) were with BMI >23kg/m^2 and 256 (76.9%) were with BMI <23kg/m^2.

Descriptive statistical analysis has been carried out in the present study. Continuous measurements were computed as Mean±SD, categorical measurements were presented in number (%).The calculations were performed by SPSS version 21 software and the results were considered statistically significant with $P \leq 0.05$. Student t-test (two tailed) has been used to find the significance of study parameters on continuous scale between two groups. Pearson correlation was used to study association between various anthropometric measurements to find the degree of relationship. Cutoff values of neck circumference to identify overweight and obesity were obtained by analyzing the ROC (receiver operating characteristic) curves. A perfect score will have an AUC of 1, whereas AUC of 0.5 means that test performs no better than chance. The best cutoff values were established for male and female children separately.

RESULTS

A total of 333 children who met the inclusion criteria were included in this study. Based on BMI, 44(13.2%) boys and 33(9.9%) girls were identified as overweight/obese. Table 1 shows mean anthropometric measurement values in both boys and girls. The mean weight, height, BMI, WC, HC, WHR were 63.16±10.03 kg, 158.33±8.2 cm, 25.27±2.09 kg/m^2, 81.05±10.41 cm, 88.14±10.4 cm, 0.92±0.05 cm respectively in obese/overweight boys. The mean weight, height, BMI, WC, HC, WHR were 59.00±7.3 kg, 153.14±7.1, 25.17±2.23 kg/m^2, 78.36±10.07 cm, 87.03±10.3cm, 0.90±0.10 respectively in obese/overweight girls. All of the anthropometric parameters were found to be significantly higher in overweight/obese children than with their normal weight peers and higher in boys compared to girls. The mean neck circumference in overweight/obese boys and girls was 33.43±2.3 and 31.50±1.4 cm respectively. The neck

circumference in boys was significantly greater than girls and higher in overweight/obese with P <0.001. Table 2 presents the Pearson's correlation coefficients between neck circumference and other anthropometric parameters for boys and girls. Neck circumference showed a strong positive correlation with BMI, WC and waist hip ratio in both boys and girls.

Table 1: Comparison of anthropometric measurements between controls and overweight/obese in boys and girls.

Boys (mean)	controls(normal/underweight)	Over weight-obese	P value
Age (years)	14.84±1.1	15.23±1.4	0.065

Neck circumference	ROC results to predict obesity				Cut-off	AUROC	SE	P value
	Sensitivity	Specificity	LR+	LR-				
Boys	81.82%	89.06%	7.48	0.20	>32	0.885	0.032	<0.001
Girls	84.85%	87.50%	6.79	0.17	>30	0.912	0.028	<0.001

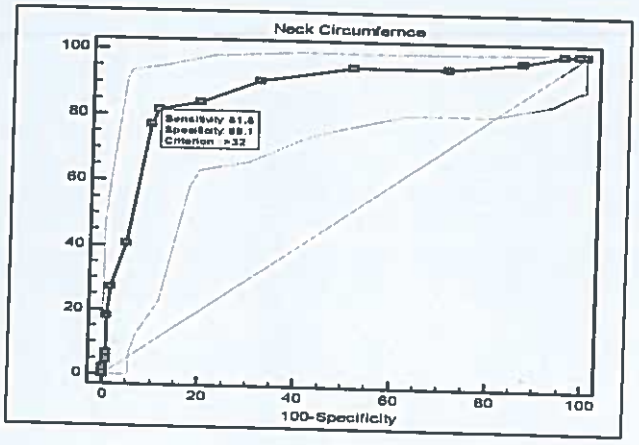

Figure 1: ROC for NC in boys

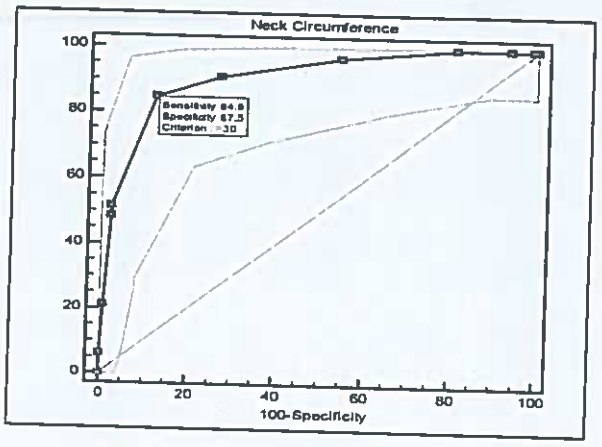

Figure 2: ROC for NC in girls.

Table 3 shows the AUC (area under curve) including the optimal NC cutoffs. Neck circumference cutoff value in boys was 32cm with the corresponding sensitivity of (81.82%), specificity (89.06%), positive LHR (7.48) and negative LHR (0.20). Neck circumference cutoff value in girls was 30cm and the corresponding sensitivity was (84.85%), specificity (87.5%), positive LHR (6.79) and negative LHR (0.17)

DISCUSSION

The present study conducted on children aged 13 - 17 years had shown a significant association between neck circumference and other anthropometric measurements of obesity in both boys and girls.

Childhood obesity has become a major public health problem in children. Many studies had shown increased adverse health outcomes of childhood obesity both short-term as well as long-term consequences.[6,18] Controlling the epidemic of childhood obesity, detection, early prevention and treatment of childhood obesity are important priorities that need accurate diagnostic measures. Screening and monitoring tools must be low-cost, quick and easy to use, and generally acceptable to both patients and health practitioners.

Several methods are available for assessing obesity in children and include weight, WC, WHR, BMI and weight height ratio. BMI may not reflect body fat distribution and waist circumference measurement though reflect central obesity it is time consuming, cumbersome and may be effected by post prandial abdominal distension, bowel dysfunction etc. Direct measurement of body fat by USG, DEXA, CT etc are expensive and not feasible and hence anthropometric measures which are reliable and easy to perform at point of care should be used.

Studies conducted in adults had shown that neck circumference can be used as a simple screening tool for identifying individuals with high BMI with good inter and intrarater reliability and various studies had found an association between neck circumference with other obesity indices.[7-9] However, there are limited studies on the neck circumference measurement as an index of obesity in the paediatric age group.

Vague J was the first person to suggest that different body morphology and type of fat distribution are associated with the health risk of obesity and used a neck skin-fold to assess upper body fat distribution.[10]

Hatipoglu et al suggested NC can be used as an additional measure to screen children with overweight and obesity and also found a positive correlation between NC and BMI, WC. The cut-off values that showed higher sensitivity and specificity for NC to detect overweight in pre-pubertal and pubertal period were 28 -31 cm for girls and 29-32.5cm for boys respectively.[11]

A study conducted by Nafiu et al on 1102 children aged between 6-18 years had shown that NC correlated with age, BMI, and waist circumference in both boys and girls and NC cutoff values were given according to age, optimal NC cutoff indicative of high BMI in boys ranged from 28.5-39 cm, in girls 27-34.6 cm respectively.[12] Similar results were also found in other studies by Roberta de et al and Mozaffer et al.[13,14]

Some studies shown association between neck circumference and increased risk of adverse health consequences of excess weight. Renata et al shown association of neck circumference and high blood pressure in children and adolescents.[15] Katz et al had shown that neck to waist ratio, an index of body fat distribution predicts obstructive sleep apnoea in overweight/obese children.[16] Another study conducted in 324 Greek children aged 9 - 13 years found that NC was associated with most cardiovascular disease (CVD) risk factors. The study showed that the association of NC and CVD was comparable to the observed co-relations of BMI, WC, hip circumference (HC), waist-to-hip ratio (WHR) and WHtR with CVD.

The present study had similar results with other studies. Neck circumference cutoff value in boys was 32 cm with sensitivity of (81.82%), specificity (89.06%), in girls was 30cm with sensitivity was (84.85%), specificity (87.5%). Neck circumference is a reliable and inexpensive, quick and easy to measure than other indexes of adiposity.

The study had some limitations that it was a cross-sectional observation study with small sample size and limits its interpretation as to causality of associations. Although neck circumference had a strong correlation with various obesity parameters there is a need to derive and validated neck circumference cutoff for different pubertal stages, different BMI catagories and different age groups for our Indian population.

CONCLUSION

The findings of the present study are consistent with other studies in children and adolescents, so we conclude that neck circumference could be a useful, simple screening measure for identifying overweight/obese children.

Indexing

Authors should cross-check the authenticity of claims of indexing before submitting to IABCR. We strongly encourage authors to take 'informed decision' before submission of any manuscript. In order to help the authors to take 'informed decision', we are providing web-links/proofs beside most of our claims of indexing or journal evaluation services. In addition, authors should visit the official site of the indexing organization or journal evaluation services before submitting any manuscript. We hope scholarly communities will appreciate our efforts to maintain integrity and transparency.
